Introduction

ASCONE Corporation thanks you for purchasing KOMPAS-3D system and hopes you will find it a reliable and trustworthy partner in your daily work that will significantly expand the scope of tasks addressed with CAD at your enterprise.

The main task solved by the KOMPAS 3D system is modeling products in order to reduce the design period and getting them in production as soon as possible. These goals are achieved due to:

- ▼ fast generation of design and process documentation required for product manufacturing (assembly drawings, BOMs, detailings, etc.)
- ▼ making product geometry available to structural simulation software,
- ▼ making geometry available to development packages of CNC processing stations,
- ▼ creating additional views of products (for example, when creating catalogues, making illustrations for technical documentation, etc.).

The main components of KOMPAS 3D are the three-dimensional solid modeling system, a graphic drafting editor and a BOM (Bill Of Materials) design system.

The three-dimensional solid modeling system is designed for creating three-dimensional parametric models of standalone parts and assemblies that contain both original and standardized structural elements. Parametric technology helps to quickly create models of typical parts based on a once designed prototype. Numerous utilities facilitate solving collateral tasks of design and production line maintenance.

The graphic drafting editor serves to automate design and development activities in various branches. It can be well used in Mechanical Engineering, Architecture, Civil Engineering, making plans and diagrams — wherever you need to develop and produce graphical and text documents.

Graphic and text documents in KOMPASGraphic are created in the same way as in KOMPAS3D, therefore, while working with KOMPASGraphic, one can use the first and second volumes of the present User Guide.

BOM design module can be used together with any of KOMPAS3D components, allowing producing various BOM, schedules and other table documents.

A BOM document can have associative relations with an assembly drawing (its one or multiple sheets) and the three-dimensional assembly model.

KOMPAS 3D functionalities and interface were developed to accommodate typical Engineering Design techniques.

We assure you that you made a right choice by starting collaboration with ASCONE Corporation — one of the leading firms developing Computer Aided Design systems!

How to use the Guide

We hope that acquaintance with description of work in KOMPAS-3D will be useful both for non experienced users and for those who already know the previous system versions (3.x and 4.x, that work in MS DOS environment, as well as 5.x and higher, that work in Windows environment).

The designer who starts to create drawings using the automated design system for the first time, should better first receive basic knowledge on the computer and Windows OS. The contents of the present Guide is intended for a user who already has initial knowledge and skills to work with Windows, namely: work with menus, windows, dialogues, control elements contained in dialogues, etc.

The first volume of the Guide contains information on the system interface, general work methods, as well as detailed description of commands to create and edit objects in graphic documents. The second volume deals with creation of drawings and text documents, describes the document printing procedure, and also service functions. The third volume is devoted to 3D modeling in the system KOMPAS-3D.

An experienced user familiar with Windows and SAPR systems, can ignore the beginning of the Guide, selecting only those chapters that contain description of the concerned function or specific attributes to perform an operation.

Conventions and Abbreviations

To make the text shorter, the following scheme is used to describe the selection of commands from the menu: **Name of a Main Menu Item — Name of the Command Group** (if available) — **Command Name**.

For instance, if the command description writes «...call the command **Highlight — Layer — By Instruction...**», it means that you have to perform this sequence of operations.

1. Select the item **Select** in the Main menu.
2. In the list of commands of the menu **Select** that appears, select the group **Layer**.
3. In the list of layer highlighting methods, that appears, select command **By instruction**.

A similar scheme is used to describe the setup process: **Service — Options... — Name of the Setup Dialogue Tab — Section Name** (group of setup objects) — **Subsection Name** (subgroup of setup objects).

For instance, if the text says: “...call the command **Service — Options — New Documents — Graphic Document — View Arrow...**”, this means that it is necessary to perform such an operational sequence.

1. Select the item **Service** in the Main menu.
2. Select the command **Options...** in the list of commands of the menu **Service** that appears.
3. In the dialogue that appears, activate tab **New Documents**.
4. In the object setup list (located in the left part of the tab) open the **Graphics Document** section.
5. Highlight item **View Arrow**.

If the described command can be called with a button, the icon of this button is to be located in the left field of the paragraph. If the text mentions any buttons, icons, cursors, etc., the corresponding images are also to be located in the left field.

The names of keyboard keys are in angle brackets and italicized. The key combinations are recorded using the "plus" sign, for instance, *<Ctrl> + <F6>*. Such a record means that one should press the key *<Ctrl>*, and then, without releasing it, press the *<F6>* key.

Notes, tips and especially important details are highlighted with horizontal lines and marked with the following signs:

— Note,

— Tip,

— Attention!

Technical support and maintenance

In the case of any installation and operation problems of the KOMPAS system, as well as HASP operation problems, it is recommended to perform the following actions.

1. Refer to the system documentation and try to find information about correcting the encountered errors.
2. Refer to the interactive Help system.
3. If possible, please visit the Internet page of the Technical support service of ASCON company with answers to frequently asked user questions.

Customer technical support site:

<http://ascon.net/support/>

4. If the mentioned sources do not have recommendations regarding the problem you have, get help from the technical support service of your vendor of KOMPAS products (the regional dealer).

Address and phone number of the regional dealer: _____

5. If your vendor could not help you with the problem, please contact ASCON directly.

1. Preliminary Information

1.1. System Installation

1.1.1. System requirements

KOMPAS-3D is intended for use on personal computers based on Intel-compatible platforms running on following operating systems (Table 1.1.1).

Tab. 1.1.1. Supported operating systems

OS	KOMPAS-3D 32-bit version	KOMPAS-3D 64-bit version
MS Windows 8 and later	+	+
MS Windows 7 SP1 and later versions	+	+
MS Windows Vista SP2 and later versions	+	+

The KOMPAS-3D 64-bit version can be installed on a PC with the 64-bit OS version only.

Minimum possible PC configuration for system **installation** and **launch** is the same as for the respective operating systems.

Free disk space required for the installation is specified in Table 1.1.2.

Tab. 1.1.2. Hard disk space required for installation

The installable part of the installation package	KOMPAS-3D 32-bit version	KOMPAS-3D 64-bit version
Pro version	1.5 Gb	1.5 Gb

DVD-ROM drive is required for installation from the distribution disk.

To obtain hard copies of documents use any printers and plotters with available driver for Windows version installed on your PC.

Please note during configuration selection that requirements to computers increase along with tasks complexity growth (drawings saturation, assemblies' complexity).

Operating speed of KOMPAS-3D on a certain computer depends also on PC components' (CPU, RAM etc.) specifications. Ask your vendor about optimum PC configurations.

1.1.2. Installation, launching and deletion of KOMPAS-3D

The KOMPAS-3D system is installed on a computer as follows.

1. Installation of the Basic package. At the same stage, security dongle software is installed.
2. Security dongle connection to computer USB port.

It is recommended to shut down antiviral programs and firewalls (e.g Windows Firewall) during the KOMPAS-3D system installation.

Protection of KOMPAS-3D against unauthorized access is described in Appendix VIII on p. 2121

1.1.2.1. Installation of the Basic Package

In order to install the Basic package onto your computer hard disk please do the following.

1. Start Windows.
2. From the KOMPAS-3D distributive disk, launch the *Setup.exe* file from the following folder: *KOMPAS-3D_V15\KOMPAS-3D*.
3. Follow installation program prompts.

Specify the necessary installation type in **Installation type** window — **Complete** or **Custom** (Fig.1.1.1).

Fig. 1.1.1. Selecting installation type

The first option means installing all system components onto the computer. The second option means selection of components to be installed (fig.1.1.2, 1.1.3).

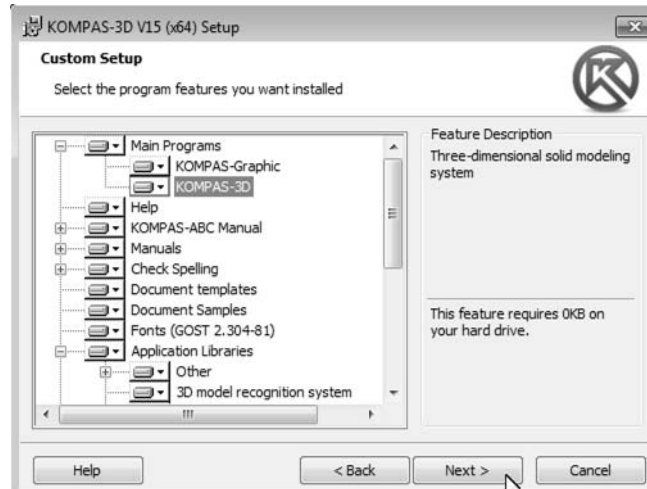

Fig. 1.1.2. KOMPAS-3D component selection

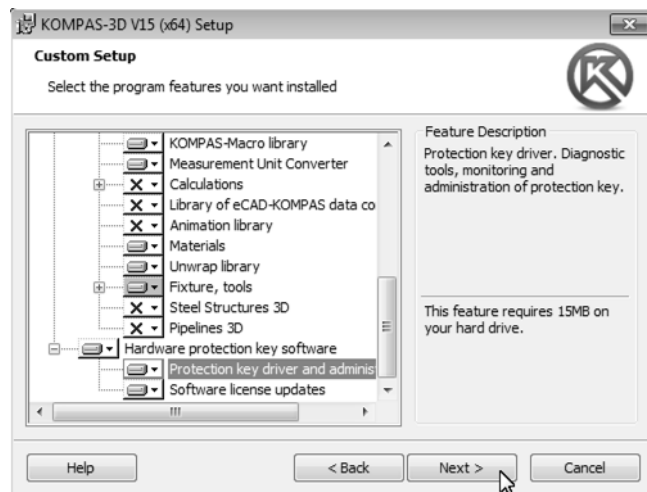

Fig. 1.1.3. Security dongle programs selection

Installation program will copy system files sequentially from the CD to the specified folder on the computer hard disk and then unpack them.

4. If you have to terminate installation before its normal completion for any reason click **Cancel** button.

1.1.2.1.1. Features of KOMPAS-Macro applied library installation

To install KOMPAS-Macro applied library, select this component in KOMPAS system installation window (Fig.1.1.4).

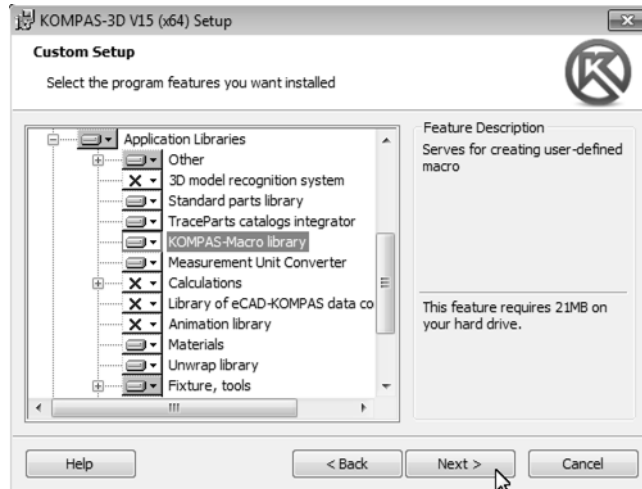

Fig. 1.1.4. System components selection

Python Pywin32 language extension is installed onto computer automatically together with KOMPAS-Macro applied library.

1.1.2.1.2. Preparation to working with the Materials library

In order to connect the “old” database, copy its *MatSort.mdb* file to the *..\\ASCON\\KOMPAS-3D V...\\Libs\\Materials* folder. Then, run the *Materials.exe* file located in the same folder in order to convert the database. Wait until the database is converted and close the library. This conversion is performed only once and will not be repeated afterwards.

For correct operation of the library, users should be granted rights to save in the *..\\ASCON\\KOMPAS-3D V15\\Libs\\Materials* folder.

If the library's database is located in a different folder, the library setup program should be started (*MaterialsCfg.exe*) from the *..\\KOMPAS-3D V15\\Libs\\Materials* folder, and path to the database should be specified.

1.1.2.2. Installation of fonts

Fonts needed for KOMPAS documents execution are installed automatically during KOMPAS-3D installation (see Table 1.1.3):

- ▼ Fonts containing symbols those face corresponds to GOST2.304–81 «ESKD. Drafting typefaces»,
- ▼ fonts containing special symbols.

Font files are copied into the system folder *Fonts*.

Tab. 1.1.3. KOMPAS-3D fonts

	TrueType fonts	Vector fonts
	font name; file name	font name; file name
GOST2.304–81 “ESKD. Fonts typefaces”	GOST type A; <i>gost_a.ttf</i> GOST type B; <i>gost_b.ttf</i> GOST type AU , Unicode font; <i>gost_au.ttf</i> GOST type BU , Unicode font; <i>gost_bu.ttf</i>	GOST type A (plotter); <i>gost_a.fon</i> GOST type B (plotter); <i>gost_b.fon</i>
Special symbols	Symbol type A; <i>symbol_a.ttf</i> Symbol type B; <i>symbol_b.ttf</i>	Symbol type A; <i>symbol_a.fon</i> Symbol type B; <i>symbol_b.fon</i>

1.1.2.3. Possible problem fixing

1.1.2.3.1. System and updates installation, installation recovery

1. During the installation process, we recommend to disable all protective software installed on the machine, such as antiviruses and firewalls (for example, the Windows Firewall).
2. Problems may appear during system installation, update or recovery due to features of users accounts control (UAC). Therefore, if user accounts control is active on the computer, it is recommended to deactivate it for installation, update and recovery period and activate it again after completion of the task.
3. A message about Windows® Installer work termination may appear during KOMPAS-3D installation or configuring. Possible reason is outdated Windows® Installer version (below 4.5). In order to obtain more information and download the Windows® Installer, visit the Microsoft website.

<http://www.microsoft.com/download/en/details.aspx?displaylang=en&id=8483>

Once the Windows® Installer is updated, launch the installation process again.

4. KOMPAS-3D requires Microsoft.NET Framework version 4.0 or a version installed on the machine. Microsoft.NET Framework has to be installed, and the computer should be rebooted prior to starting the KOMPAS-3D installation.

Installation package of Microsoft.NET Framework (*dotNetFx40_Client_x86_x64.exe file*) is available on the KOMPAS-3D distributive disk.

You can also install Microsoft.NET Framework from the Microsoft website:

<http://www.microsoft.com/en-us/download/details.aspx?id=24872>

1.1.2.3.2. Working with applications and libraries Help systems

Operating systems Microsoft Windows Vista and Microsoft Windows 7 contain no program for viewing help in HLP format (files with HLP extension) that was included in previous Windows versions. Therefore, Help systems cannot be used while working with a number of applications and libraries in KOMPAS-3D.

In order to obtain more information and download the HLP help viewer application, visit the Microsoft website.

<http://support.microsoft.com/kb/917607/en-us>

1.1.2.3.3. Displaying KOMPAS documents

In KOMPAS-3D, models are always displayed on the screen using OpenGL. Graphical documents can also be displayed using OpenGL (this is the default method in the Construction configuration). Drawing with the use of OpenGL is possible with hardware acceleration and without it.

If the machine, on which you plan to work with KOMPAS-3D, does not provide enough software and hardware support of OpenGL, display defects and failures may appear when working with KOMPAS-3D.

Possible solutions are presented below.

1. PC upgrade, which may consist of as follows:

- ▼ video card driver update,
- ▼ video card replacement and installation of the respective driver.

Stable operation with built-in video cards (those located on the PC's motherboard) is not guaranteed. We recommend to use video cards with graphical processors.

- ▼ NVIDIA:
 - ▼ Quadro FX 380, 580, 1800 and later;
 - ▼ GeForce of 7XXX series and later;
- ▼ ATI (AMD):
 - ▼ FirePro V5700, V7750, V8700;
 - ▼ FireGL V5600, V7600, V7700, V8600;
 - ▼ Radeon of HD2XXX series and later.

Drivers for video cards can be downloaded from the following websites: NVIDIA (<http://www.nvidia.com/download/index.aspx?lang=en>) and AMD (<http://support.amd.com/en-us/download>). You will have to provide the required information.

2. Disabling hardware acceleration (drawing may slow down).

- ▼ In order to disable hardware acceleration when displaying graphical documents, call the **Service — Parameters — System — Graphical Editor — Image Management** command and disable the **Use Hardware Acceleration** option in the right section of the appearing dialog. Restart KOMPAS-3D.

- ▼ In order to disable hardware acceleration when displaying models, call the **Service — Parameters — System — Model Editor — Image Management** command and disable the **Use Hardware Acceleration** option in the right section of the appearing dialog. Restart KOMPAS-3D.
- 3. Disabling OpenGL (for graphical documents).
In order to disable OpenGL, call the **Service — Parameters — System — Graphical Editor — Image Management** command and disable the **Use OpenGL** option in the right section of the appearing dialog. Restart KOMPAS-3D.

1.1.2.4. Security dongle installation

Security dongle should be inserted in a free USB-port.

No further actions required, since the KOMPAS-3D system checks automatically if a dongle is installed on the computer.

1.1.2.5. Starting KOMPAS-3D

In order to begin working with the system, call **KOMPAS-3D** command from the program group **ASCON — KOMPAS-3DV...** This program group is created automatically during system installation onto hard disk.

Once started, KOMPAS-3D automatically restores its condition at the end of the previous session (loaded documents, window size and location, etc.).

If the previous session has been terminated abnormally (power outage, etc.) with auto save enabled, upon restart the system will restore the opened documents using their temporary copies.

After running KOMPAS-3D for the first time, you will see the main system window without any open document windows. To display remaining interface elements on the screen you shall open a document (see Section 1.3.4.1 on p. 72).

You can also start KOMPAS-3D and simultaneously open a document, for example, by double-clicking the document file's name in the Windows Explorer. In this case, there are several things to take into account.

After starting the system using this method, libraries, that were connected when the previous session was terminated, will not be connected to KOMPAS-3D this time, as well the documents open during the previous session will not be loaded. If, during the session after starting the system in this way, libraries are connected and/or documents are opened, the respective information will not be saved after termination of the current session.

1.1.2.6. Uninstalling KOMPAS-3D

KOMPAS-3D can be uninstalled as normal via the Windows control panel.

All system files are deleted from subfolders of the main system folder during KOMPAS-3D deletion. The resulting empty subfolders are also deleted.

The following files are not deleted (remain in the same folders on the disk):

- ▼ configuration files **.ini*, **.cfg*, **.dsk* и **.prj*,
- ▼ KOMPAS-3D fonts.
- ▼ security dongle driver,
- ▼ files saved in the main folder and its subfolders (document template files, text templates, various libraries etc.).

While working with KOMPAS-3D, users may make changes to any supplied lines style library files (**.lcs*), hatches (**.lhs*), layouts (**.lyt*). Furthermore, users may edit user menu file (*Graphic.pmn*), densities reference file (*Graphic.dns*).

During the KOMPAS-3D deletion, among others, all supplied libraries and files *Graphic.pmn*, *Graphic.dns*, located in *\SYS* subfolder are deleted, no matter if they were edited by the user or not. If these files should be retained for any reason, make their backup copies before KOMPAS-3D deletion.

1.2. System Interface

1.2.1. System window

KOMPAS-3D is a standard Windows application. That is why the workspace you see after launching the system and loading a document is virtually identical to other application windows (Fig. 1.2.1).

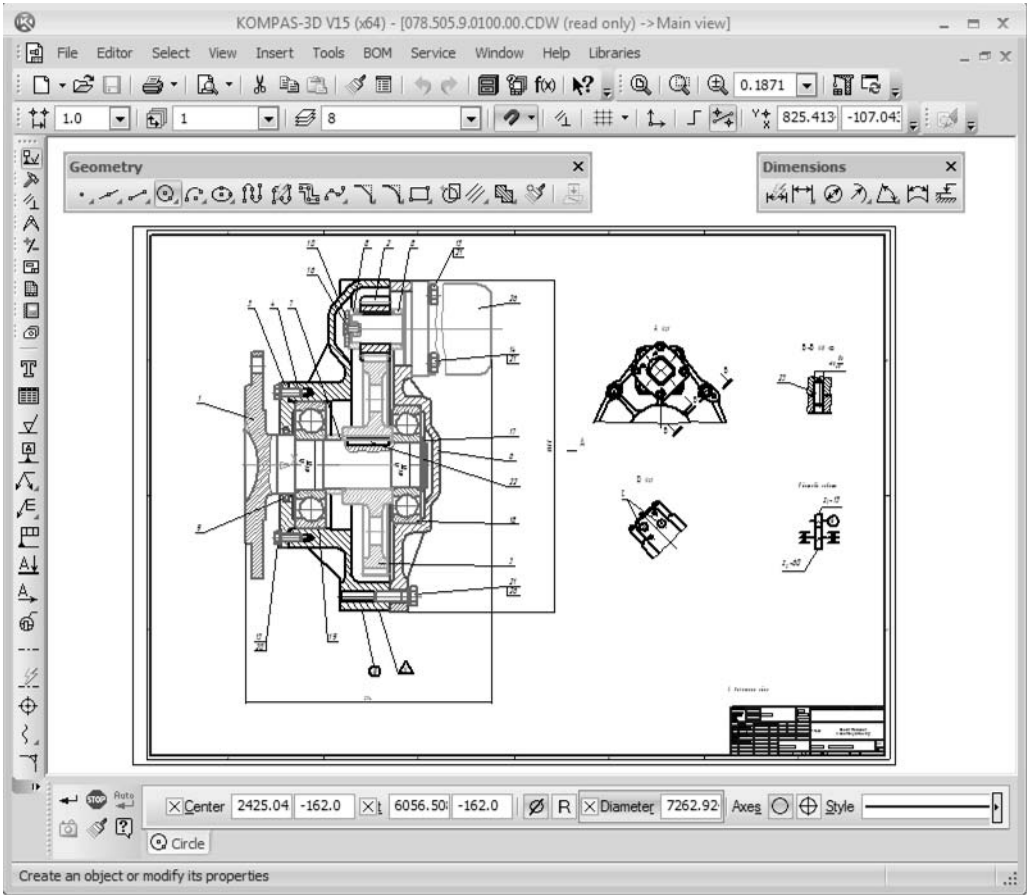

Fig. 1.2.1. KOMPAS-3D interface elements

The functions of the KOMPAS-3D interface elements are represented in Table 1.2.1.

Tab. 1.2.1. KOMPAS-3D interface elements

Name	Description
Header	Contains name, system version number, current document* name, system menu button and the system window management buttons.
Main menu	Serves to call system commands. Contains names of menu pages. The Main Menu contents depend on the current document type and system work mode.
Toolbars	Contain system command calling buttons.
Compact Toolbar	Contains several toolbars and the buttons to switch between them (for more information, see Section 1.2.2.1.1 on p. 53). Compact bar contents depend on the active document type.
Variables window	Serves to work with variables and expressions (for more information, see Section 7.1 on p. 1569).
Library Manager	Serves to work with KOMPAS-libraries. For details on Library Manager, see Section 12.1.1 on p. 2035.
Properties bar	Use this bar to set up an object when during its creation or editing (more details can be found in Section 1.2.2.1 on p. 52).
Line of messages	Contains system messages that are relevant to the current command or to a working window element pointed at by the cursor.
Tree model	Displays the model (drawing) creation order and links between its elements and components. Can only be placed inside the Document window (for more — see Sections 2.1.2 on p. 104 and 3.6.1.1 on p. 1207) .

* In order to choose a variant of file name display (full or short), call the **Service — Parameters...** command. — **System — General — File names displaying** command.

The Header and the System main menu are permanently displayed on the screen. Display of remaining interface elements is controlled by a user. Commands for enabling or disabling these elements can be found in the **View — Toolbars** menu.

1.2.2. Bars (panels) and windows

1.2.2.1. Toolbars

All toolbars presented in the KOMPAS-3D window by default, can be subdivided into two groups.

- ▼ The first group contains **Standard**, **View** and **Current Status** bars. These bars contain the buttons to call the commands to work with a document as a whole (saving, scale editing commands, etc.). However, only some commands are universal and can be used when working with a document of any type. Therefore, depending on the type of the current document the contents of the first group bars are changing: buttons for command that are not required at the moment are deleted while buttons for required command are added.
- ▼ The second group contain all remaining toolbars. They contain buttons for calling commands for creating and editing objects related to a certain document type. Buttons on bars are grouped by function and they form an advanced command bars (see Section 1.2.2.1.2).
The second group bars are grouped into the system compact bars for every document type (for more about compact bars see Section 1.2.2.1.1).
Object types are determined by a document type (for example, a drawing can not contain bodies, a model can not contain views). Therefore, when switching to another type of document, components of the compact bar, i.e. toolbars contained in it, will change completely.
Display of bars is enabling and disabling by commands that are located in the **View – Toolbars** command submenu.

After connecting libraries to KOMPAS-3D, their toolbars become available.

A bar displaying of which is enabled can be in the “floating” or fixed state. “Floating” bar can be located in any place of screen, fixed— only inside KOMPAS-3D window with docking at some of its borders.

To fix a bar next to a border of window, drag with the mouse at its title to this border. To return a bar to a “floating” state, perform a reverse action, namely, drag it in the window center direction.

If the bar is fixed, then instead of the title there is an embossed line by the left or top end of the bar.

For quick switching between “floating” and fixed bar state, you can double click its title.

If necessary, you can create user-defined toolbars and place on them buttons of any commands (see Section 9.4.2.2 on p. 1874).

1.2.2.1.1. Compact bars

Fig. 1.2.2. System compact bar used when working with a graphic document

The compact bar contains a number of toolbars represented by buttons for switching between them and by buttons for calling commands of the active bar. Activation of a certain toolbar is performed using switch buttons.

By default KOMPAS-3D, the system compact bar is displayed in window. It contains toolbars for creating and editing objects related to the document of a given type.

You can change contents of the system compact bar. Next to the switch buttons there are drag markers. To remove a toolbar from the system compact bar, “drag” its respective marker by the mouse outside the system compact bar.

Release the mouse button. The selected toolbar will appear on the screen. Its respective button will disappear on the system compact bar.

Any toolbars, except **Standard**, **View**, **Current Status** and also compact bars, can be grouped into a user-defined compact bar.

To do this, press and hold the <Alt> key and then “drag” one bar to another with the mouse at its title. When, upon overlapping the panes, the “+” sign appears next to the cursor, release the mouse button, and then release the <Alt> key. The user-defined compact bar will be created. It is automatically assigned with name “Compact bar № N”, where N is a sequential number of user-defined compact bar.

To restore or add a toolbar in the compact bar, “drag” the toolbar’s heading so that it “overlaps” the compact bar, keeping the <Alt> button pressed. After the “+” sign appearance, release mouse button and key. Toolbar will be included into the compact bar.

1.2.2.1.2. Advanced Command Bars

Buttons for calling commands are grouped by their purpose and represented on the toolbar by the button of a command of the group. If a command’s button is clicked and kept clicked, an **expanded bar** appears next to the button comprising all commands of a given group. For example, an advanced bar called by the **Arcs** button of the **Geometry** bar contain different methods of arcs creation: by three points, tangent to curve and other.

The buttons that produce an additional command bar are marked by a small black triangle in the lower right corner (Fig. 1.2.3, a).

The expanded command bar can be transformed into a separate bar with a generalized heading, for example **Arcs** (Fig. , b).1.2.3

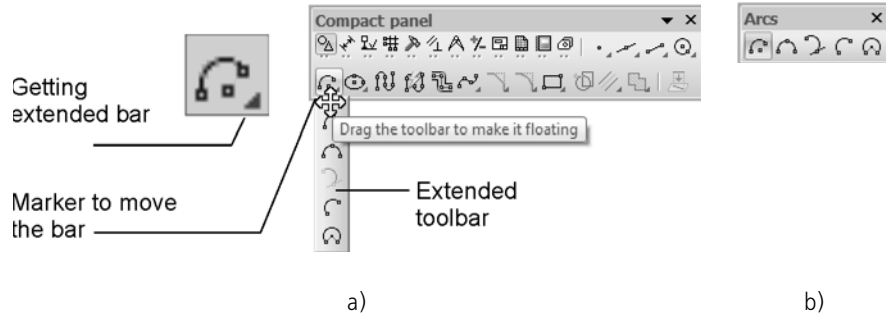

Fig. 1.2.3. Extended Command Panel:
a) within the toolbar, b) separate

 To detach the extended panel from the toolbar, perform the following actions. On the command button: Call the extended panel, keep the left mouse button pressed, move the cursor to the drag marker— “wavy” line at the panel edge. After the cursor turns into a four-sided arrow, release the mouse button— the extended panel shall stay on the screen. Click the mouse left button and drag the panel to any place on you screen.

To delete a separate expanded bar from the screen, close it. Create it again, if you want it back. Individual expanded bars cannot be included into compact bars; you cannot change the button set and their order in expanded bars.

Commands on separated expanded bars and on toolbars are equally available for calling. At the same time, expanded bars can be used without having a toolbar on the screen which was used to create them.

1.2.2.2. Windows

A window is widely used in KOMPAS-3D as a control element. This is a specific section of the screen. You can modify the size and position of this section. The main part of the window is a field for information entry and output. Windows can have their own toolbars. Examples of windows: Variables Window, Library Manager, **Properties** window, **Numbering** window, **Technical requirements** window, **document tree** (for assembly) window, and an additional Tree window. Some windows, for example, the **Document Tree** window, are parts of documents. Therefore, they can only be positioned inside the document window. Other windows (like the **Properties** window) belong to the whole KOMPAS-3D system and can be positioned in any part of the screen.

Property bar is also a window (see Section 1.4.2.1 on p. 82).

1.2.2.3. Controlling the state of bars and windows

Bars and windows may be displayed on the screen in one of the following two states: “floating” or fixed.

If necessary, you can fix positions of both floating and fixed bars and windows (see Section 1.2.2.3.5).

Bars can be fixed beside a border of a system window. To fix a bar, drag with the mouse at its title to the required border. To return a bar to a “floating” state, perform a reverse action, namely, drag it in the system window center direction.

Windows that belong to a document (such as **Document Tree** and **Technical Specifications**) can be fixed next to the vertical border of the document’s window. Such windows can be fixed in the same way as bars, i.e. by “dragging” their header with the mouse.

Other windows belong to the whole KOMPAS-3D system and can be fixed next to any border of a KOMPAS-3D window (**Numbering** and **Properties** windows can be fixed only next to vertical borders). The windows can be fixed in the following way:

1. Hover the mouse's cursor over the window's header, press the left button and move the mouse.

In the center of the KOMPAS-3D window and beside those its borders where the window being moved can be fixed, control elements for selection of its position appear.

2. Move the mouse button to the required control element.

In the KOMPAS-3D window, the border area, which will be occupied by the window being moved, will be highlighted by color.

3. If the position of the window is what you need, release the mouse button.

The window is fixed next to the chosen border.

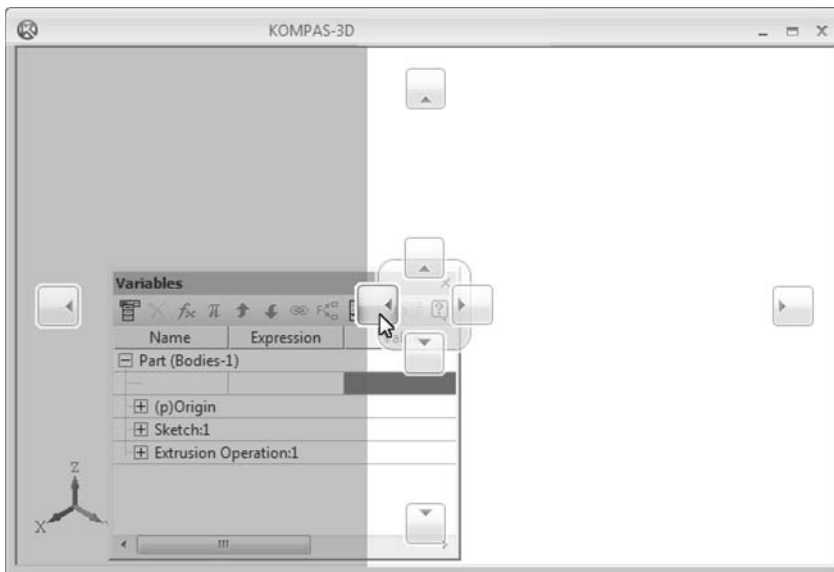

Fig. 1.2.4. Fixing the Variables Window next to the left border of the system window

To lock the property bar near the required system window boundary, you can also use **Location – Up/Down/Left/Right** commands from the contextual menu of the Bar.

For quick switching between “floating” and fixed bar or window state, you can double-click its header.

1.2.2.3.1. Combining windows

Windows with similar fixation variants (to any KOMPAS-3D window border or to vertical borders only) can be combined. The windows can be combined in the following way:

1. Hover the mouse cursor over the header of one window, press the left mouse button and move the mouse, so that the cursor is positioned within the borders of the second window.

Control elements for selection of the first window's position will appear in the center of the second window (Fig. 1.2.5, a).

2. Move the mouse button to the required control element. In the second window, the area to be occupied by the first window (the one being moved) will be highlighted in gray color.

- ▼ The central control element makes it possible to combine windows by overlapping them; in this case, tabs will be formed (Fig. 1.2.5,b).

- ▼ Other controls make it possible to combine windows by dividing the area of the second window vertically or horizontally (Fig. 1.2.5, c).

3. If the position of the window is what you need, release the mouse button.

The first and the second windows are combined forming a single window.

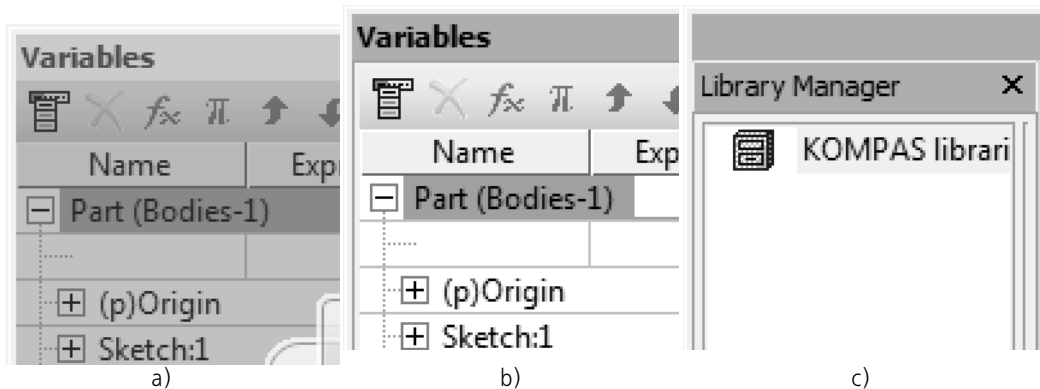

Fig. 1.2.5. Combining windows:

a) combination variant selection, b) window with tabs, c) window divided vertically

In order to overlap windows with forming tabs, you can also “drag” the first window to the second window's header.

1.2.2.3.2. Combining the Properties window with the Property bar

The purposes of the **Properties** window and the Property bar makes it impossible to use them at the same time: the **Properties** window is used for changing properties of selected objects, while the Property bar is designed for specifying properties of an object being created (edited). To save screen space, you can combine the **Properties** window and the Property bar in a single window. You can do this in one of the following ways:

- ▼ by calling the **Location — Combine with the Properties window** command from the Property bar's context menu,
- ▼ or by calling the **Combine with the Property bar** command from the context menu of the **Properties** window's header.

The combined window is positioned vertically; it can be fixed beside the vertical border of a KOMPAS-3D window.

Depending on the currently performed operation, the combined window displays:

- ▼ the Property bar — during creation (editing) of an object,
- ▼ the **Properties** window displaying objects' properties — if selected objects are present in the window,
- ▼ the empty **Properties** window — if there are no selected objects.

If you need to cancel the combining:

- ▼ if the combined window displays the Property Bar, call the **Location — Combine with the Properties window** command from the context menu or disable the display of the Property Bar and enable it again;
- ▼ if the combined window displays **Properties** window, call the **Combine with the Property bar** command from the context menu in its header or disable the display of the **Properties** window and enable it again.

1.2.2.3.3. Automatic minimization of windows

A window (including windows formed by overlapping or combining with other windows), fixed beside a system window or document border, can be automatically minimized to the border. This allows to use working field more effectively: if you do not work with a window, it will disappear automatically, and its label will be visible on the border of the system window or document with its name displayed. In order to display the minimized window on the screen and continue working with it, place the cursor in the label's area.

In order to enable/disable automatic minimization of the window, use the **Fix** button in its header.

1.2.2.3.4. Commands for controlling a window's status

To manage a window's status, use contextual menu commands in its header (Tab. 1.2.2).

If the Property bar is docked horizontally (by the top or bottom border of the system window), then instead of the title there is an embossed vertical line by the left end of the Bar (see Fig. 1.2.1 on p. 51).

Tab. 1.2.2. Window status management commands

Name	Description
Floating	Switches a docked window into the “floating” state. The Floating command is not available, if automatic minimization of a window is enabled, or if floating windows' position is fixed.
Fixed	Docks a “floating” window. Once the command is called, the window will be fixed near the border where it was positioned before becoming the “floating” one. The Fixed command is not available, if automatic minimization of a window is enabled, or if docked windows' position is fixed.
Minimize	Enables automatic hiding of a “fixed” window. To disable the auto hide, call the command again. Hiding a docked window can be controlled also by the Fixation button located in the window's header. The button image will change after the clicking, which indicates the auto hide mode:  <ul style="list-style-type: none"> — window's automatic minimization is enabled, — window's automatic minimization is disabled.
Close	Closes a window. After closing the window, it will disappear from the screen. To display it again, you will need to call the window display command.

If the **Technical Specifications** or **Document Tree** window is in the “floating” state, it can be displayed with different transparency degrees. In order to adjust transparency, call the **Transparency — N%** command from the window's header (Fig. 1.2.6). If you left-click a transparent window, it will become non-transparent.

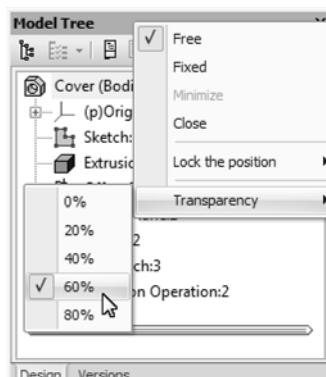

Fig. 1.2.6. Example of window transparency adjustment

On a PC with Microsoft Windows XP, there is no **Transparency** command in the context menu of the **Technical Specifications** and **Document Tree** “floating” windows' headers. The **Technical Specifications** and **Document Tree** windows are displayed as non-transparent.

1.2.2.3.5. Fixation of bars and windows

You can fix positions of bars and windows. For this purpose, call the **View — Toolbars — Fix position** command. The submenu with the following commands will be displayed: **Floating bars**, **Fixed bars**, **Floating windows** and **Fixed windows**. Commands can also be called from the window's header context menu or from the menu of the arrow button on the bar's header (Fig. 1.2.7).

Fig. 1.2.7. Example of calling the command

As a result of fixing the position:

- ▼ the following operations will be blocked for bars and windows:
 - ▼ movement
 - ▼ resizing
 - ▼ switching between the “floating” and fixed states by double-clicking the header;
- ▼ the following operations will be blocked bars:
 - ▼ modification of commands' order and set,
 - ▼ separation of expanded command bars and menus (for fixed bars);
- ▼ the following context menu commands will become unavailable for windows:
 - ▼ **Floating**,
 - ▼ **Fixed**.

If a window is formed by combining other windows, fixing its position will block their borders' movement (in case of external borders, only if the window is fixed).

During interface setup (see Section 9.4.2 on p. 1872), bars' fixation will be temporarily disabled. You can modify the order of commands, the set of command, as well as control their display mode.

If you try to move a fixed bar or window, the cursor will be transformed into a warning symbol.

In order to temporarily disable fixation of bars and windows, press and hold the **<Ctrl>** key.

1.2.3. Document Window Management

KOMPAS-3D allows working simultaneously with several different documents.

Any document, whether a newly created one or opened for editing, is displayed in a separate window.

If necessary, you can work with the same graphic document or model document in several windows. In order to open an extra document window, call the **New Document Window** command from the **Window** menu or from the context menu of the document's tab. Different parts of a document can be displayed in different windows to different scales.

Each window has a title that contains the name of the displayed document, the system menu button and the window management buttons.

The techniques of using windows are standard (dragging a window by the header, resizing the window, etc.) and identical to those of other Windows applications. To conveniently arrange document windows on the screen, use the commands **Cascade** and **Tile...** in the **Window** menu.

Any document window can be minimized to a button, or icon. This can be convenient in the case, when the document is needed only temporarily, and the user would prefer not to close it at all. To orderly place document icons (which are usually displayed in the bottom part of the main KOMPAS-3D window), use the **Window — Arrange Icons** command.

To cyclically switch through document windows, you can use the <Ctrl>+<F6> keys combination, and for random access — the **Window** menu commands. Additionally, you can use document tabs to select the current document (see Section 1.2.3.1 on p. 61).

Managing documents and windows is also possible in the **Windows** dialog called by the command **Window — All Windows**.

The view window of the dialog lists all windows open during the current session.

Select one or several documents in this list and perform one of the following actions using the relevant buttons:

- ▼ activate (possible when one document is selected),
- ▼ save,
- ▼ close,
- ▼ cascade,
- ▼ tile horizontally,
- ▼ tile vertically,
- ▼ minimize.

The **Cascade**, **Horizontally**, **Vertically**, and **Minimize** buttons are available in the **Windows** dialog, if displaying of tabs is disabled (see Section 1.2.3.1 on p. 61).

1.2.3.1. Document tabs

The main purpose of the tabs is to enable quick switching between document windows. The document's file names are displayed in the document's tabs (Fig. 1.2.8).

You can enable or disable tabs using the **Window — Display Tabs** command. If a check mark is displayed next to this command in the menu, the tabs are displayed.

Location and appearance of tabs, document file names format (full or short) are adjusted in the document tab setup dialog (see Section 9.1.3.7 on p. 1684). You can also enable and disable tabs in the dialog.

Tabs can be used only with maximized document windows. Therefore, when enabling tabs display, all windows maximize automatically. The **Minimize** and **Restore** system buttons for windows will disappear, while the **Close** button will be placed on the right on the current document's tab or in the tab row depending on the setup (see Section 9.1.3.7 on p. 1684).

In order to enable a document's window, click its tab and select the required document in the list which is displayed after clicking the arrow button in the right part of the tab row (Fig. 1.2.8).

Fig. 1.2.8. Document Tabs

The document tab's context menu contains the following commands:

- ▼ **Save;**
- ▼ **Save as;**
- ▼ **Close window;**
- ▼ **Close all other windows;**
- ▼ **Close all;**
- ▼ **Close other document windows;**
- ▼ **New document windows;**
- ▼ **Open folder with file;**
- ▼ **Copy full name of file;**
- ▼ **Customize...;**
- ▼ **All windows...**

In order to close a window, double-click the left mouse button or click the middle mouse button (wheel) once on the document's tab.

In order to create a new document, double-click the left mouse button on a free space of the tab row.

If displaying document tabs is enabled and more than one window is opened, the workspace of the main system window can be divided into several parts (see Section 1.2.3.2).

1.2.3.2. Workspace

You can divide the workspace of the main system window into several parts. One or several document windows can be in each of them.

Splitting is possible when more than one window is open (as well as for one document) and tabs are shown.

To split the workspace vertically, “drag” any tab by the mouse into a document window or to the right-hand border of the workspace. The workspace will be divided in two parts. The document window, whose tab was moved, will be on the right-hand part, while the other windows — on the left part.

The left part can be divided in two more parts in the same way, provided that it still has more than one window.

Horizontal splitting of the workspace can be done in the same way. For this purpose, “drag” any tab to the lower border of the workspace.

You can move windows across sections by “dragging” the tabs by the mouse from one section to another.

To change sections width, “drag” their borders by the mouse.

To return to the original view of the work area (i.e., put all of its parts back together), “drag” to any part of the work area the tabs of all windows that are outside this part.

1.2.4. Context menus and context bars

The context menu appears when you right-click the mouse. The menu contents depend on the object on which the cursor rested when you right-clicked and on the action being performed. The menu contains the most typical commands at the given project stage (Fig. 1.2.9).

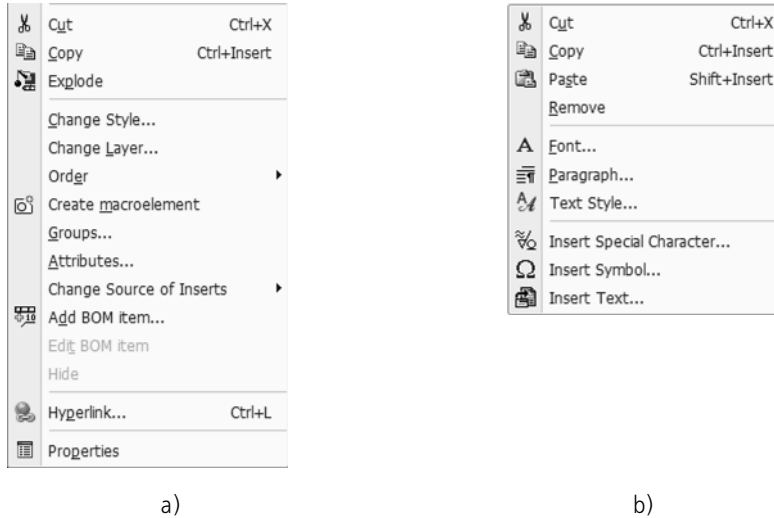

Fig. 1.2.9. Contextual menu:
 a) for several selected geometric objects,
 b) for the selected text fragment

The context toolbar is displayed:

- ▼ when objects are selected in the document window,
- ▼ when objects are selected in the Drawing Tree or in the Model Tree,
- ▼ At a mouse click in any free space of the document
- ▼ when the context menu is called, except when calling the context menu during some command execution.

The context bar includes the most frequently used command buttons. The bar content depends on the type of the selected object, the document type and the current work mode.

The context bar will not appear when selecting the following objects:

- ▼ designations for civil engineering
- ▼ Designations for mechanical engineering, except for leaders and position designation,
- ▼ Bent radial dimension and level dimension
- ▼ OLE-insert.

In Fig. 1.2.10, you can see some context bars.

Fig. 1.2.10. The context toolbar when you select: a) a geometric object in a drawing or fragment, b) a body face in an assembly, c) a text fragment in a text document, d) a geometric object in a 3D element sketch

You can configure contents of the context bar. This can be done with the **Customizing Interface** button in the right part of the toolbar (Fig. 1.2.11).

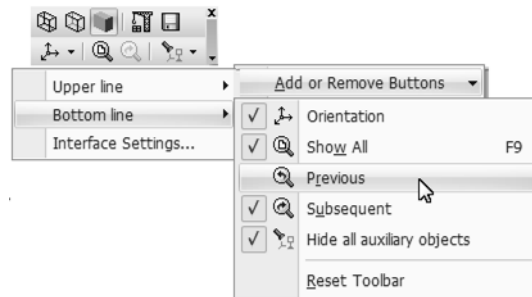

Fig. 1.2.11. Configuring contents of the context bar

Besides, you can set up display parameters for the context toolbar (in particular, it can be disabled in documents of one or another type). To do this, call the **Service — Parameters... — System — General — Context bar**.

The context bar appearing at context menu call does not include the **Customizing interface** buttons.

The context bar looks semi-transparent, but becomes non-transparent when pointing the cursor on it. The context bar disappears when moving the cursor out of the selected object or calling any command.

The convenience of context menu and toolbars is provided for by grouping together commands scattered across various sections of the main menu but frequently used in work. Moreover, commands are activated quicker because the context menu is displayed in the screen area, where it was called by a mouse click, and the context toolbar — near the cursor.

Press the <Esc> key to close the context menu and/or context bar.

1.2.5. Mode icons in the document window

Mode icons serve to inform the user of the current mode of the object (model, graphic object, BOM item, etc.) and to exit from the mode.

An icon that corresponds to the mode button on the panel and which appears in the document window when the system switches to a particular mode and disappears when leaving it. Several icons can simultaneously display in the Document window.

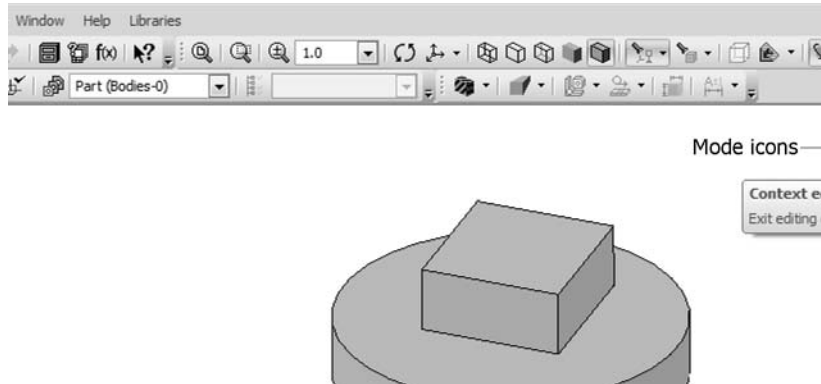

Fig. 1.2.12. Mode icon displaying

The **Show mode icons** command from the **View** window serves to control the appearance of icons on the screen, while commands from the icon's context menu are used for location in the document window.

Icons are displayed for the following operating modes:

- ▼ editing graphical macroelement,
- ▼ editing technical requirements,
- ▼ editing BOM items,
- ▼ sketch,
- ▼ flat pattern,
- ▼ recalculating of dimensions based on tolerances,
- ▼ context editing,
- ▼ components exploding,
- ▼ model section,
- ▼ preview mode before printing,
- ▼ editing the title block table.

In order to exit the mode, you will need to click the icon.

1.3. KOMPAS-3D Documents

1.3.1. Document Types

The type of the document created in the KOMPAS-3D system, depends on the type of information stored in that document.

Each document type has a file name extension and an individual icon.

1.3.1.1. 3D Models

Part

Part — model of the product manufactured using a homogeneous material without assembly operations.

A part file has the *m3d* extension.

Assembly

An **Assembly** is a model of a product consisting of several parts with a certain mutual position.

The assembly can include other assemblies (subassemblies) and standard products.

An assembly file has the *a3d* extension.

Technological assembly

The **Technological assembly** is an assembly that contains technological data, for example, the result of model size recalculation taking account of tolerances, technological objects (center holes, mounting holes, and so on), technological models (lunettes, centers, instruments, and other equipment).

The technological assembly's file has the following extension: *t3d*.

1.3.1.2. Graphic documents

Drawing

A main type of graphic document in KOMPAS-3D — **drawing**. A drawing contains a graphical image of the item, a title block, a border, sometimes — advanced layout elements (a symbol of unspecified surface finish, the specifications, etc.). A KOMPAS-3D drawing may contain one or several sheets. For each page, you can set format, multiplicity, orientation and other properties. Aside from drawings (in terms of USDD — the Unified System of Design Documentation), the file of the drawing KOMPAS-3D may contain diagrams, posters, and other graphical documents.

A drawing file has the *cdw* extension.

Fragment

A special type of graphic document in KOMPAS-3D — **fragment**. Fragment differs from a drawing because of absence of border, title block and other document layout elements. It is used for storing drafts that do not need to be laid out as a separate sheet (such as sketches, roughs, etc.). Additionally, you can use fragments to store standard solutions for further use in other documents.

A fragment file has the *frw* extension.

1.3.1.3. Text documents, BOMs

Bill of Materials (BOM)

Specification is a document with information about the contents of assembly represented in the form of a table. BOM uses a format frame and a title block. It is often multipage.

A BOM file has the *spw* extension.

Text Document

The document that contains mostly text info — **text document**. Text document uses a format frame and a title block. It is often multipage. You can create explanatory notes, notifications, technical specifications and so on, in a text document.

A text document file has the *kdw* extension.

1.3.2. Coordinate systems and measurement units in documents

1.3.2.1. Coordinate Systems

When working with KOMPAS-3D the standard right-hand oriented Cartesian coordinate systems are used.

In every graphic and model document there is an absolute coordinate system. It is not possible to delete it from the document.

In a 3D model, the coordinate system defines coordinate planes. The coordinate system is conventionally displayed on the screen as three orthogonal segments, while planes are represented as rectangles lying in these planes. If needed, local coordinate systems may be created. For detailed description of coordinate systems in 3D models, see Section 2.8.3 on p. 595.

The coordinate system in a graphical document is located in a plane parallel to the screen, and is displayed as two orthogonal arrows. If needed, local coordinate systems may be created. For detailed description of coordinate systems in graphics documents, see Section 3.1.5 on p. 887.

1.3.2.2. Measurement Units

Standard metric system of measurements is used in KOMPAS-3D.

Default length unit — millimeter.

These units are used to set and display linear parameters (for example, length of the segment, circle radius, offset value) on the property bar, values in dimension texts of the dimensions, cursor coordinates, and so on.

You can set other length unit for graphic documents— centimeter or meter (see Section 9.2.6.2 on p. 1760).

Default angular unit— degree.

Angular parameters are set and displayed in these units (for example, arc opening angle or rotation angle of an object copy) on the Properties bar. You can set other angular units for the Properties bar fields— degrees, minutes and seconds, radians (see Section 9.1.2.2 on p. 1668).

Values in dimension texts of angle dimensions are expressed in degrees by default. You can set another unit— degrees and minutes or degrees, minutes and seconds (see Section 9.2.6.10.1 on p. 1771).

When calculating mass-inertia properties, you can control the representation of results choosing the required units directly in the measurement process (kilograms or grams for mass; millimeters, centimeters, decimeters, or meters for length).

When drawing in KOMPAS-3D, **the user always uses real dimensions of objects** (1:1 scale), while the image's positioning on the drawing of the required format is ensured by choosing the appropriate scale view (see Section 3.5.4.1 on p. 1161).

1.3.3. Creating and saving documents

1.3.3.1. Creating Document

To create a new document, click **File — Create**.

A document creation dialog will appear (Fig. 1.3.1).

Fig. 1.3.1. Dialog to Create a Macroelement

On the **Templates** tab you can select the desired template for the new document.

If you do not need a template, then select the document type on the **New Documents** tab.

Click the **OK** button to create a document of a specific type or by a specific template.

Another way to create a new document is selecting it from the **New** menu button. (Fig. 1.3.2).

The commands of this menu can be placed as buttons on a separate bar and then moved to any convenient location. To do this, drag the **New** button with the mouse at its title in any direction. The **New Document** toolbar will be created (Fig. 1.3.3).

Fig. 1.3.2.

Fig. 1.3.3.

Note the difference between the **New Document** bar and the other toolbars: you cannot change the composition or the order of buttons on them.

Default templates and formats are used to create new documents. If necessary, you can customize the template and the format of an active document (see Sections 3.5.2.1 on p. 1151 and 4.1.5.2 on p. 1343).

1.3.3.2. Saving Document

To save a document to a file on your hard drive, call the **File— Save** command.

The document will be saved automatically to the same folder and file as the previous time. In other words, the file created last time you saved a document will be replaced with a new file containing the document with changes.

If necessary, you can save the document under a different name or in a different folder (see Section 1.3.3.2.2).

1.3.3.2.1. Saving a Document for the First Time

To save the document, click **File — Save**.

The Save file wizard dialog will appear. Specify the folder to which you would like to save the document, enter the filename, and click **Save**.

By default, the system suggests a file extension matching the document type.

Do not change the standard document file extension unless it is absolutely necessary, as this will make it difficult to find the file in the future (it will not be displayed in the list of documents of this type).

When you try to save a document to the existing file, the request will pop up to confirm rewriting (replacement of the old document with a new one). If the existing document is open at the moment, it cannot be replaced with a new one; the write failure message will pop up.

After the File Save dialog closes, the Document Summary dialog will appear (see Section 1.3.5 on p. 73).

1.3.3.2.2. Saving Document under a Different Name

Sometimes you may need to save, a document after editing, while keeping the old file version unchanged. In this case, save the document under a different name or in another location on the disk.

Call the command **File—Save As...**

The further steps are identical to those when saving a document for the first time (see Section 1.3.3.2.1). The only difference is that the Document Summary dialog will not appear.

In addition, the **Save as...** command allows you to save KOMPAS-documents as templates for new documents, convert KOMPAS-documents to other formats, and, when working with 3D models, you can save a part in an assembly file and an assembly - in a part file. To save the document as a template, for conversion or to change model type select the required line from the **File Type** list.

1.3.3.2.3. Saving All Documents

To save all open documents at once, click **File — Save All**.

When saving documents that are being written on a disk for the first time, a standard dialog will appear, in which you need to define the file name and the storage location. After this dialog closes, the Document Summary dialog will appear.

1.3.4. Opening and closing documents

1.3.4.1. Opening Document

To open an existing document, click **File — Open**.

In the dialog that appears, select the document type, specify the filename, and click **Open**.

You can also open a KOMPAS-3D document using Windows Explorer. To do so, in Windows Explorer double-click the file you need to open or right-click the file and select **Open** in the context menu.

If you attempt to open a document, which has already been loaded for processing, KOMPAS-3D will not open it again, but rather activate this document window.

If you have recently edited a document and then closed it, you can reopen it faster. In the bottom part of the **File** menu, a list of the last nine documents, with which you had worked, is displayed. Indeed, this is a list of documents in the order in which those were closed. To open the desired document, simply select its name in the menu.

You can configure the number of recently opened files that are displayed in the **File** menu. To do this, call the **Service — Parameters... — System — General — File names displaying** command.

You can open documents from one folder on by one without calling the **File— Open** command or using Windows Explorer.

To switch between documents, **Previous document** and **Following document** commands are used.

The preceding (following) document with respect to a given document is the document contained in the same folder as the given document and preceding (following) it, if sorted by file type.

When calling the **Previous document** command, the preceding document with respect to the current one is opened in the active window. If the **Following document** command is called, the next document is opened.

Thus, if the current document had been opened from a window, this document will be closed when **Previous document** and **Following document** commands are called.

If the document opened in active window is the last in the file list sorted by type, **Next Document** command is unavailable. If this document is the first one, the **Previous document** command is unavailable.

The **Previous Document** and the **Next Document** are the viewer application commands. In order to use these commands in KOMPAS-3D, add them to any menu or bar (see Section 9.4.2.1 on p. 1872).

1.3.4.2. Closing a document

To close a document, call the **File — Close** command.

If any changes to the document have not been saved, a prompt will be displayed about saving the document being closed.

If the document was displayed in several different windows, all those windows will close.

To close only one document window and leave the remaining windows open, double-click the system menu button of the window you want to close.

1.3.5. Document Information

The document information is various reference data about this document, which are stored with it, such as the author's name, creation date and time, attributes, etc. You can view and edit these data in the **Document Information** dialog (Fig. 1.3.4).

Click **File — Document Information...** to open this dialog. The dialog appears automatically when you save a document for the first time. The document summary dialog control elements are presented in Table 1.3.1.

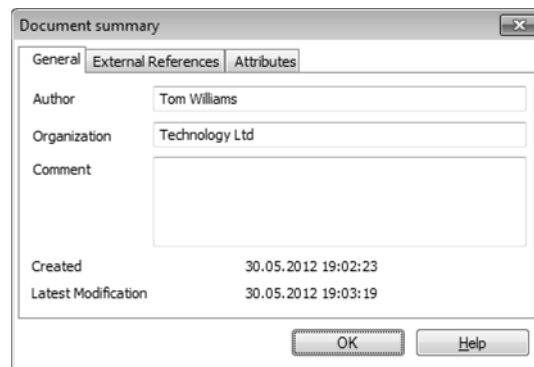

Fig. 1.3.4. Document Info Dialog

Tab. 1.3.1. Document Info Dialog

Element	Description
Tab General Information	Contains general document information.
Author	Author's name.
Organization	Company name.
Comment	Document comments. A comment can span multiple lines.
Created	Document creation date and time*.
Last Modification	Date and time of last document saving*.

Tab. 1.3.1. Document Info Dialog

Element	Description
Tab External Link	<p>The viewing pane of this tab lists all external files referenced by this document, and with which it is linked:</p> <ul style="list-style-type: none"> ▼ Format libraries ▼ Fragment libraries ▼ Style libraries ▼ Attribute type libraries, ▼ BOM documents attached to the current assembly or drawing, ▼ Assemblies or assembly drawing sheets attached to the current BOM, ▼ Documents attached to the BOM objects in the current document, ▼ Documents, whose BOMs the current document is connected to, ▼ Inserted fragments ▼ Files of parts related with associative views ▼ files of the parts and assemblies inserted in the model, ▼ E-mail addresses and external hyperlinked files.
Whole Path	<p>If the full path and filename do not fit into the viewing window, the path will be compressed. To view the full path to the file, check the Full Path option.</p>
Save to File	<p>Button that lets you save information on the document's external links shown in the page window to a text file.</p>
Tab Attributes	<p>This tab appears when viewing the information about a graphics document or a BOM. It contains a list of attribute types assigned to the current document.</p>

* This field is filled in automatically and cannot be edited by the user.

By default, the author and company information match those specified when installing KOMPAS-3D (in the **User Information** dialog). This information, including comments, may also be obtained from document properties (see Section 5.1.4.1.1 on p. 1385).

If necessary, you can modify the default data (see Section 9.2.3 on p. 1748).

1.4. General Document

1.4.1. Using the Document Viewing

1.4.1.1. Graphic Cursor

The cursor is the main working tool in KOMPAS-3D. The cursor is used to execute commands from menus and buttons, create and edit objects, and perform numerous other actions.

The shape of the cursor depends on the active document type and the operation being performed.

The standard shape of the cursor located within the field of a graphic document or model document is a square “trap”. The cursor parameters (size, color, etc.) can be customized. This customization is made in the dialog activated by the **Service — Settings... — System — Graphic Editor — Cursor** command.

The following methods on cursor controlling are possible.

- ▼ **Moving using the mouse** is the main method that is available in all types of documents.
- ▼ **Moving using the keyboard.** You can move the cursor by using the arrow keys on the main or extended keyboard. In this case, the movement will not be arbitrary as in the case of using the mouse, but rather incremental.

When within a text document and BOM (while entering the text portion of the object), pressing an arrow button moves the cursor by one character or one line.

The minimal increment of the cursor motion in graphical documents, as governed by clicking an arrow button, obeys the defined cursor step. The cursor step value can be specified in the **Cursor's Current Step** on the **Current Status** bar. The step value can be entered from the keyboard or selected from the list. To quickly activate the **Cursor's Current Step** field, use the keyboard shortcut *<Shift> + </>* (press the *</>* key on the numerical keypad). The list of steps and default step can be specified in the cursor setup dialog (see Section 9.1.7.1 on p. 1703).

- ▼ **Setting Cursor Coordinates.** When working with graphic documents, you can enter the coordinates of the point where the cursor should be placed in the **Cursor Coordinates** on the **Current Status** bar.

To quickly activate these fields, use the keyboard shortcut *<Alt> + <X>*. After pressing it, the X coordinate field becomes active. Enter the desired value there. To go to the Y coordinate field, press the *<Tab>* key. Enter the value.

Confirm the new cursor coordinates value by pressing the *<Enter>* key.

You can specify the increments of the current coordinates in the cursor coordinate fields. To do this, enter the *^* character, and then — the increment value

If the **Current Status** bar is arranged vertically, click the relevant buttons to access the **Cursor's Current Step** or **Cursor's Coordinates** fields.

- ▼ **Fixing the cursor.** In graphic documents and model documents, after you set the cursor in the desired point you need to **fix** it — confirm that this exact point should be used for creating the object.

You can fix the cursor by left-clicking the mouse or pressing *<Enter>*.

For example, to create a line you need to specify and fix its start and end points. When creating a hole in a model, you can change its default location, specifying and fixing a new location of the anchor point.

1.4.1.2. Document view scale

KOMPAS-3D offers a wide selection of tools for zooming the image. It must be understood that changing the image scale does not affect the actual size of the objects (part dimensions, line length, font size, etc.). To draw an analogy: a sheet with a drawing is attached to a drawing board, and you are moving relative to it. When you move to or from the drawing, you will see a bigger or smaller image.

The zoom commands are grouped under the **View** menu. The main ones can be called by the buttons on the **View** bar.

The set of available commands for zooming the image depends on the current document type.

The commands for zooming the image in or out and specifying the zoom factor are available at all times.

The automatic scale setting is available when you work with text documents or BOMs, enter BOM text, and in some other modes.

The remaining zoom change commands are available in graphic documents and model documents.

1.4.1.2.1. Zooming Image In or Out

To zoom the image in or out, click **Zoom In** or **Zoom Out**.

By default, the zoom factor is 1.2.

In order to change the factor for model documents, call the **Service — Parameters...** command. — **System — Model Editor — View Control** command.

In order to change the factor for graphic documents, call the **Service — Parameters...** command. — **System— Graphic Editor— Edit** command.

In order the change this factor for text documents, reports and BOMs, call the **Service — Parameters...** command — **System— Text Editor— Edit** command.

In the right-hand part of the appearing dialog, type in or select from the list the desired value of the **Scale Change Factor**.

By default, when you work with graphic documents and models, the buttons for zoom in or zoom out are not available on the **View** toolbar. You can add these buttons to the toolbar (see section 9.4.2.1 on p. 1872).

1.4.1.2.2. Explicit Setting of Image Scale

The view scale in the current window is shown in the **Current Zoom** field on the **View** bar.

To change the scale, unfold the list and select the desired value. You can also type the value on the keyboard.

If the bar is positioned vertically, click the **Current Zoom** button to access this field.

If you need to set the current scale factor to 1.0, use the **Scale 1.0** command.

1.4.1.2.3. Zooming in a Random Image Section

To zoom in a random image section, click **Zoom In by Marquee**.

Click with the mouse on the first corner location of the zoom area. Then move the cursor to get the desired marquee size. The ghost marquee box will be reflected on the screen.

After fixing the second corner of the box, the image will be magnified so that the document portion within the frame will fit in the entire window.

1.4.1.2.4. Zoom to Selection

You can set the maximum view scale so that all objects selected in the document will fully fit in the window (fit the scale to the size of the selected group of objects).

To do this: click **Zoom to Selection**.

Selected construction lines and empty (containing no objects) views are ignored when running the command. A single selected point is also disregarded.

The **Zoom to selection** command is inaccessible if no object has been selected (see Section 3.1.3 on p. 876 for techniques of selecting objects).

1.4.1.2.5. Smooth Zooming

If the required zoom factor is unknown, you can select it visually by zooming the image in or out.

To do this: click **Zoom In/Out**.

The external cursor appearance will change.

Press the left mouse button and move the cursor vertically. As the cursor moves up, the image will be smoothly zoomed in, in the reverse direction — zoomed out. The center of scaling is the point, in which the left mouse button was pressed. When you reach the end of the screen, release the mouse button, move the cursor to the middle of the screen and then press again the left mouse button and move the mouse.

To have the panning center in the center of the screen, hold the *<Shift>* key pressed.

If you are using a mouse with a wheel, then you can spin the mouse wheel to pan the image. The panning center is at the point, where you start moving the wheel. You can also adjust the direction of the mouse's wheel rotation (see Section 9.1.2.10 on p. 1678).

To have the panning center in the center of the screen, hold the *<Shift>* key pressed.

The mouse wheel can be also used for panning an image in text documents and BOM documents. To do this, rotate the wheel and keep pressed button *<Ctrl>*.

1.4.1.2.6. Display the whole sketch

You can set the maximum view scale of the current sketch so that it is fully fit in the model window. To do this, call the **Show the sketch in full** command.

Construction lines and projections, created in a sketch are ignored when running the command.

1.4.1.2.7. Displaying Entire Document

To display the entire document being edited, call the **Show All** command.

1.4.1.2.8. Transition to the Previous or Next Display Scale

When working with graphic documents or models, you can return to one of the previous display scales in the window.

To return to the previous scale, call the **Previous Zoom** command.

To advance to the next scale, call the **Next Zoom** command.

1.4.1.2.9. Auto Scale

You can change the scale of the current text document, specifications, report, title block table or BOM so that the document page will fully fit in the window horizontally (the horizontal size of the image becomes equal to the window width) or vertically (the vertical size of the image becomes equal to the window height).

For the scale to be set automatically, call the **Zoom to Page Height** or **Zoom to Page Width** command.

1.4.1.3. Moving the Image

Moving (scrolling) the image means moving the document in the window without changing the image scale.

It must be understood that image offset in the window not affect the actual objects position in the document. To draw an analogy: a sheet with a drawing is attached to a drawing board, and you are moving relative to it. As you move to the left, to the right, up or down, your field of vision will include not the entire image but only a part of it.

To move an image while working with a graphic document or model, call the **View — Move** command or press the **Move** button of the **View** toolbar.

The cursor will change its shape.

The Move command can be actuated by pressing the keyboard shortcut **<Shift>+<Ctrl>** and then the left mouse button.

Move the cursor while holding the mouse button pressed (if you have actuated the command using the **<Shift>+<Ctrl>** keyboard shortcut, hold these keys as well). When you reach the end of the screen, release the mouse button, move the cursor to the middle of the screen and then press again the left mouse button and move the mouse.

Once the working field is moved into the desired position, release the mouse button and the keys.

If you use a mouse with a wheel or a three-button mouse, then to move the image in a graphic, text or BOM document, move the mouse and hold the middle button or wheel pressed.

Basically, this image moving technique can be used to increase the size of the document working field. This technique is convenient to use when the range of the scroll bars is not enough.

1.4.1.3.1. Scroll Bars

The scroll bars allow moving the image either vertically or horizontally. They are displayed in the document window at the bottom and on the right.

To scroll the image in the window, keep pressing the arrow buttons located at the ends of the rulers. You can also move the slider on the scroll bar.

If you are using a mouse with a wheel, then to scroll the image while working with text documents and BOM documents you can spin the mouse wheel. To scroll page by page, you need to hold the <Shift> key in addition.

You can configure the way the scroll bars are displayed in the current window. To do this, call the **Service — Parameters... — Current window — Scroll bars**.

The **Scroll Bars** group, which controls the way the scroll bars are displayed, is located on the right-hand side of the dialog that appears.

1.4.1.4. Refresh Image

While running various creation and editing commands, auxiliary lines and symbols may be appearing on the screen. In most cases, KOMPAS-3D automatically deletes those temporary objects upon completing a command. However, sometimes you may need to force the screen cleanup from “debris” — refresh the image.

To refresh the image in the active window, click **Refresh Screen**.

The refreshing also allows re-displaying objects with corrupted images. Such corruption is caused by removing or moving one of the superimposed or overlapping objects. For example, when you delete construction lines from the screen, the drawn outline can also disappear. It will reappear after you refresh the image.

1.4.1.5. Leafing through Documents

When working with text documents or BOMs, as well as when entering BOM text, you can leaf through the document — scroll it page by page.

To move sequentially from one page to the next, press <Page Up> and <Page Down>. To go to a specific page enter its number in the **Current page** field on the **Current status** bar and press <Enter>. The cursor will be set at the start of the first line on the page with the specified number.

If the **Current status** bar is positioned vertically, then to access the **Current page** field you need to click the respective button.

1.4.1.6. Undoing and Redoing Actions

Actions can be undone and redone using the **Undo** and **Redo** commands in the **Edit** menu. The respective command buttons are located on the **Standard** panel.

Command **Undo** reverts the document to a state it was in before the last action.

Redo, repeats the reverted action. The redo command is available only after you use the undo command.

Not all commands can be undone and redone. In particular, this applies to the commands of filling the title block, removing the entire document contents, saving the document to disk.

Note that all parameter editing operations (for example, changing unit sizes) for a component inserted into the assembly from the library are considered a single operation. Thus, it is impossible to cancel one of the library component editing operation: the **Cancel** command deletes the component from the assembly, while the **Repeat** command returns it with the parameters it had prior to the deletion.

In a graphic document, besides undoing and redoing commands, you can undo and redo actions within the current command. In this case, only those actions that pertain to the given command are undone. For example, you have constructed several circles in your document. If, without ending the **Circle** command, you click **Undo**, the created circles will disappear one by one, and after you click the **Redo** button, they will be restored.

You can configure the parameters of the undoing process for graphic and text documents: set up number of steps and also enable or disable grouping of similar operations (see Sections 9.1.7.11 on p. 1713 and 9.1.8.2 on p. 1721).

1.4.1.7. Recalling Recent Commands

The last command can be recalled not only from the toolbar, but also from the context menu or the **Edit** menu. This can be accomplished by clicking **Recall: (Command)**. You can execute a command by pressing the <F4> key. Besides the last executed command, several recent commands are available in the context menu (Fig. 1.4.1).

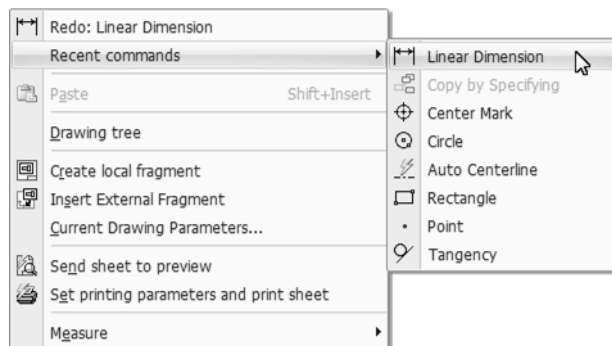

Fig. 1.4.1. Example of the recent commands list while working with a drawing
Recent commands lists are created for the following KOMPAS-3D document types:

- ▼ part
- ▼ assembly
- ▼ drawing
- ▼ fragment

- ▼ BOM
as well as for the following operating modes:
- ▼ sketch mode,
- ▼ table editing mode.

When you work with a text editor, you can recall only one last command. The recall command is executed in the **Edit** menu.

Categories of commands added to lists are shown in Table 1.4.1.

Tab. 1.4.1. Categories of commands that can be recalled depending on the document type and operating mode

Document type or operating mode name	Command categories*
Part	Edit, Tools, Select, Edit Model, Features of Sheet Body, 3D Lines, Surfaces, Construction Geometry, Dimensions and Process Symbols, 3D Measurements, Filters, BOM
Assembly	Edit, Tools, Select, Edit Model, Mates, 3D Lines, Surfaces, Construction Geometry, Layout Elements, 3D Measurements, Filters, BOM
Drawing	Edit, Tools, Select, 2D Measurements, Views, Pages Management,
Fragment	Edit, Tools, Select, 2D Measurements, Views, Pages Management,
Bill of Materials (BOM)	All edit commands, all BOM commands, commands of libraries working with BOM.
Text Document	All Commands of Text Editing
Table editing mode	Edit, Insert to Text, all table editing commands
Sketch mode	Edit, Tools, Select, 2D Measurements

* Commands included in each category are listed in the **Interface Setup – Commands** dialog (see Fig. 9.4.1 on p. 1873).

The commands are included in the list regardless of whether they have been completed or not.

A command will not be recalled if it was executed by double-clicking an object.

If the command execution conditions have not been specified, it cannot be recalled. For example, to run the **Tracing** command, it is required to select the source objects. If no object has been selected in the document, the **Copy** command will not be available in the recent commands list.

The number of “memorized” commands can be set up in the dialog which is called by the **Service – Settings... command. – System – General – Recalling commands** command. In the same dialog, you can disable the displaying of the latest commands in the context menu. At the end of a KOMPAS-3D session, the command lists are emptied.

1.4.2. General Methods of Performing Operations

1.4.2.1. Properties Bar

The Property bar (Fig. 1.4.2) serves to control the process of running a command.

Toggle the Property bar display by the command **View – Toolbars– Property bar**.

Setting the appearance of the Properties bar is described in Section 9.1.3.6 on p. 1683.

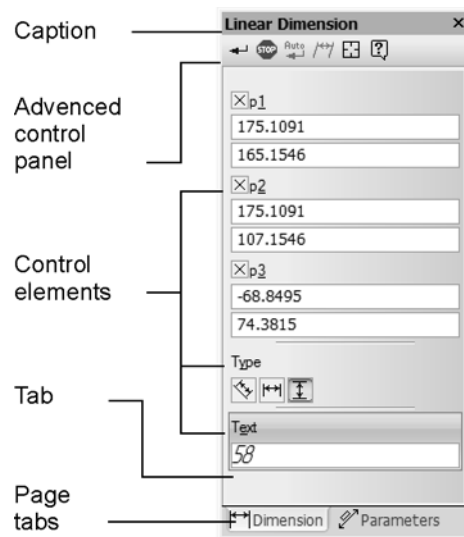

Fig. 1.4.2. Example of Property Bar

The Advanced Control Panel is located in the upper or in the left section of the Property Bar.

On the Advanced Control Panel there are the buttons, with which the special actions are executed, such as inputting an object, terminating the current command, turning On an auto object creation etc.

1.4.2.2. Property Window

The **Properties** window (Fig. 1.4.3) serves for viewing and changing the properties of the objects selected in a graphic document or in a model.

In graphical documents, the **Properties** window can be also used when copying properties between objects for viewing and selection of copied properties (see Section 3.4.1.2 on p. 1117).

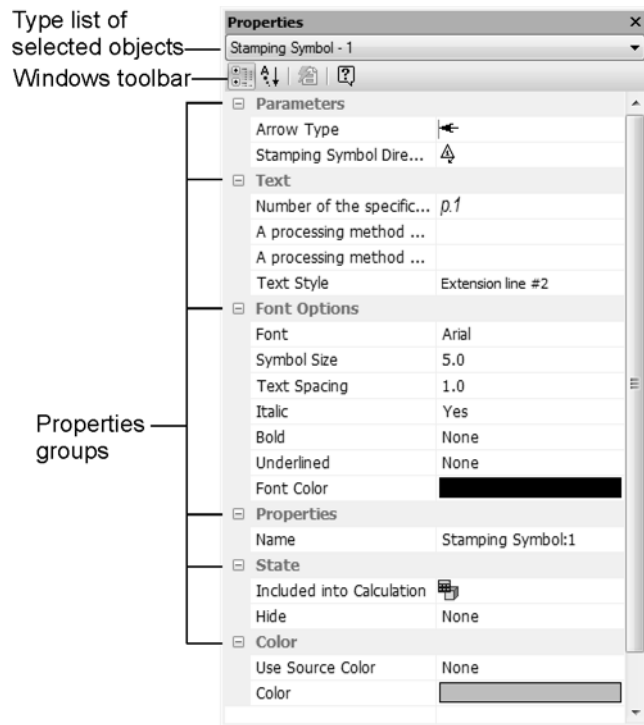

Fig. 1.4.3. Stamping symbol properties in a model

To display the **Properties** window on a screen, call the **Edit – Properties** command or press the **Properties** button in the Standard bar.

In a graphical document, the **Properties** command can be called from the context menu of selected objects.

The upper part of the **Properties** window contains a list of the types of the objects selected.

The window's toolbar can be found below the list.

The major part of the **Properties** window is occupied by a table of object properties.

The table consists of two columns. The first column contains the names of object properties, the second one contains the values of properties.

If the **Group** switch is enabled in the toolbar, the properties in the table are grouped. By default, groups are shown expanded, i.e. you can see on the sheet contents of groups— properties included in them. To minimize the group so as only its name would remain in a window, click on the “minus” icon to the left of the group name. If you click this icon again (after minimizing the group it is displayed as a “plus”), the group will be maximized.

If you enable the **Sorting** switch in the toolbar, the properties in the table will be sorted by names in alphabetical order.

The **Select by Properties** as a command button for selecting objects by a set of properties, excluding objects from the selected ones by a set of properties, and inverting the selection (for

details, see Section 3.1.3.3 on p. 879). The button is available in graphical documents.

Peculiarities of working with 3D objects in the **Properties** window are described in Section 2.14.3.6.1 on p. 793; description of working with graphical objects can be found in Section 3.4.1.2.1 on p. 1118.

1.4.2.2.1. Changing Properties

Using the **Properties** window, you can change the properties of a separate object or a group of objects without editing each of them separately. If the window is not displayed on the screen, enable it by clicking the **Properties** button.

To change the properties of objects, you must select them using any method. When editing the properties, you can add objects to the objects already selected or exclude any objects from those selected using any method.

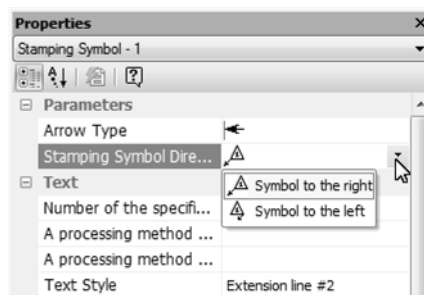

Fig. 1.4.4. Object properties changing

The list of object types in the **Properties** window contains the **All — N** line, where N is the total number of objects selected, and the lines are formed by the **Type Name — n** template, where Type Name is the name of object type and n is the number of the selected objects of this type (Fig. 1.4.4).

If there are selected the objects of one type only, then the **All** line does not present in the object type list.

If additional objects are selected or some objects are excluded from the selected ones, the list of types dynamically changes.

The table of properties represents:

- ▼ Names and values of all properties of selected objects of the same type— if a certain type of objects is chosen in the type list
- ▼ Names and values of the properties, which are common for all selected objects, if the **All** line is selected in the list of types.

Values of properties, that are not available for editing, are displayed in the cell in gray color.

To change the value of any property, perform the following operations:

1. Click the cell of the property value to be changed.
 - ▼ If the value is numerical (e.g. radius of circle), the cell will become available for its entry.
 - ▼ If the value is non-numerical (e.g. line style), the button with a black triangle appears in the right part of the cell. It makes it possible to open the list of values.
 - ▼ In case of a text value (e.g. surface finish parameter), the text input dialog will be displayed.
 - ▼ If the value is a hyperlink, the hyperlink editing dialog will be displayed.
2. Modify the property's value.
3. Press the *<Enter>* key or click outside the editable cell to confirm input of a numerical value. Close the text input or hyperlink editing dialog with the **OK** button. The non-numeric values do not require confirmation.

The objects (object) will be modified automatically in accordance with the new property value. In this case, the objects remain selected, and you can continue to change their properties.

Peculiarities of working with the **Properties** window in graphical documents are described in Section 3.4.1.2 on p. 1117; description of working with the window in models can be found in Section 2.14.3.6.1 on p. 793.

1.4.2.3. Running and stopping operations

To run an operation, you should call its respective command. For this purpose, you can choose the command name in the menu or click the respective command's button on the toolbar. For some commands, calling is possible only from menu or only from toolbar.

Once an operation has been run, the elements appear on the toolbar to control the parameters of the operation and/or object to be created in the document as a result of the operation.

To run the majority of operations, confirmation is required. To confirm operation, click the **Create Object** button on the Special Control panel or press the *<Ctrl> + <Enter>* key combination. The **Create Object** command is available in the context menu and in the **Editor** menu.

For some operations, objects can be created automatically. By default, Auto-sorting is enabled. In this case, operation is confirmed automatically right after setting the required minimum of parameters. For example, a circle is automatically fixed in graphic document if two points are defined: center and point on circle. For more information on automatic and manual creation of objects refer to Section 1.4.2.10 on p. 93.

Some operations allow to create several object of the same type in a row (or to perform several actions of the same type). For example, several segments can be built by running one segment building operation. To exit the operation after construction of the last object, click the **Interrupt command** button on the Special Control bar.

It is impossible to create several objects one by one (to perform several actions) for other operations. Such operations are automatically finalized after confirmation. For example, only one sector can be cleared using the respective operation. Pressing the **Interrupt Command** button before confirmation on operation performing means canceling an object creation (an action completing).

The **Interrupt Command** command is also available under the context menu.

To finish operation you can also perform one of the following actions:

- ▼ Press the <Esc> button,
- ▼ release the command button,
- ▼ execute any other command.

1.4.2.4. Object Parameters

After executing most of the object creation commands, you need to specify various parameters for these objects.

For example, after executing the command to create a circle, you have to specify the location of its center and its radius, and after executing the command to create an extruded solid — the extrusion direction, depth and draft value.

To create an object, it means to define all its parameters. When developing models and drawings using KOMPAS-3D, all parameters of the created objects are displayed on the Properties bar (see Section 1.2.2.1 on p. 52). Each parameter has a corresponding element on the bar (Fig. 1.4.5).

The parameters can be divided into numerical (point coordinates, length, angle, number of vertices, etc.) and non-numerical (line style, presence of axes of symmetry, etc.).

Fig. 1.4.5. Circle Parameter

A switch is provided next to the labels of most of the numerical parameters on the Property bar, which has an indicator corresponding to the parameter state (Table 1.4.2).

Tab. 1.4.2. Parameter status icons

	Name	Description
	Fixed	The box of a fixed parameter has a cross. This parameter value is accepted by the system. It will stay unchanged through the modifications of the other parameters and will be displayed on the object ghost. Any numerical parameters can be fixed.
	Active	A “check mark” is displayed on the active parameter’s box. The system expects this parameter value to be entered by selecting a point with the mouse in the document window. Active can be only the parameters representing the point coordinates.

Tab. 1.4.2. Parameter status icons

	Name	Description
	Auxiliary	The auxiliary parameter switch is empty. This parameter value is either not yet defined or depends on other parameter values (in this case, it shall be recorded automatically upon recording the parameter, on which it depends). An auxiliary parameter can be defined and fixed at any time. Before fixing, the auxiliary parameter value stays in the field. Any numerical parameters can serve as auxiliary parameters.

Unlike the non-numerical object parameters, which allow definition solely by selecting the desired choice in the Property bar, there are several ways to define numerical parameters.

- ▼ The first, most simple and obvious method of defining parameters is selecting the desired points in the document window (see Section 1.4.2.4.1 on p. 88). This method can be applied mostly to graphical objects, since among the three-dimensional objects there are too few whose parameters can be defined by specifying just points.
- ▼ The second method — entering parameters in a predefined order — allows more flexible control over the object parameters (see Section 1.4.2.4.2 on p. 88). This method is available when creating most of the objects — both graphical and three-dimensional.
- ▼ The third method is defining parameter values on the Property bar — which is less visual but universal and can be used when creating objects of any type (see Section 1.4.2.5 on p. 90).

You can combine any of the described methods of defining object parameters.

After all object parameters are defined, you need to confirm its creation. This can be done in one of the following ways:

- ▼ click the **Create Object** button on the Special Control panel,
- ▼ call the **Create Object** command from the **Editor** menu or from the context menu,
- ▼ press the keyboard shortcut `<Ctrl> + <Enter>`.

An automatic creation capability is provided in most commands for creating graphical objects (see Section 1.4.2.10 on p. 93). By default, Auto-sorting is enabled.

In subsequent descriptions of the object creation commands, the word “click” means pointing with the cursor to a specific element on the working field (i.e., placing the cursor on top of this object and left-clicking), while the word “specify” means specifying parameters in any way.

The chapters devoted to object creation describe the easiest and most commonly used ways. This applies to both the way and procedure of specifying the object properties. For example, to create a line, you have to specify its length, direction and position. You can do it like this, for example: enter the start point coordinates, then the slope angle to the X axis of the current coordinate system, and, finally, click the end point of the line with the mouse. Naturally, this way is as correct as all the others; moreover, in some cases it can be the only possible way. Still, the description of the line segment creation contains only two basic creation techniques: using two points and using one point, length and angle, since these two techniques are the easiest and most commonly used.

1.4.2.4.1. Specifying Points in the Document Window

To specify a point in the document window, it means to set the mouse pointer in it and fix.

In a graphic document and in a sketch, you can use snaps to position the cursor accurately (see Section 3.1.1 on p. 865) or the cursor coordinate fields on the **Current status** bar (Fig. 1.4.6).

Fig. 1.4.6. Cursor coordinate fields

Fixing the point at the cursor location is necessary to have this point coordinates passed to the Property bar fields (i.e., to make them the object parameters). A point can be fixed in two ways:

- ▼ by clicking the left mouse button (this fixing method is convenient if the point was selected by the mouse “by sight” or with the use of a snap),
- ▼ by pressing the `<Space>` or `<Enter>` key (this is convenient if the point is specified with the use of the keyboard — by typing in the cursor coordinates or by using keyboard snapping).

For example, to create a line segment, it is enough to specify and fix two points: the start and the end. Note that in this case not only the line endpoint coordinates will be entered in the Property bar fields, but also its length and angle (they are calculated automatically).

You can change the default sequence of specifying the points, i.e. specify the parameters in a sequence other than that offered by the system (see Section 1.4.2.8 on p. 91).

1.4.2.4.2. Entering Parameters in a Predefined Order

This method of defining object parameters implies the following.

The order of entering parameters, which are not point coordinates (length, angle, distance, name, etc.), is predefined for various objects and is stored in the system. Therefore, the value (number or text), typed in from the keyboard at the time of creating or editing an object, is instantly accepted by the system as the value of a predefined parameter and is entered in the predefined field. To cancel an entered value, press the `<Esc>` key; to fix it and proceed to the next predefined field — press `<Enter>`. When specifying a point or object in the document window, the fixing of the input value and jumping to the next parameter occur automatically.

The parameters of the predefined input can be assigned in an arbitrary order. To navigate through the predefined fields in the forward direction, use the `<Tab>` key, in the reverse direction - the `<Shift>+<Tab>` keys. Upon fixing the value in the selected field, there is an automatic jump to the next field of the predefined input.

If the currently focused field is **Text** (for example, when creating a Surface Finish symbol), then the respective dialog appears on the screen upon entering the first characters of the text.

Let's review in detail the method of inputting parameters in the predefined order on the example of creating a line segment, for which we know the start point, the length and the inclination angle. Obviously, constructing it by specifying the start and end points is not rational in the least.

Fig. 1.4.7. Property bar when creating a line segment

The predefined sequence of inputting line parameters includes the **Length** and **Angle** fields. Upon calling the **Line** command, the **Length** field is focused on in the Properties bar — it is framed and has a different background (see Fig. 1.4.7). Enter the line length. You will see this value entered in the **Length** field. Note that the field is de-focused. This happened because the Properties bar became active when you were entering a value, and the predefined entry mode is active only when the document window is active (for details on switching between the Properties bar and the document window see the following section). Specify by the mouse the start point of the line in the window. You will see a ghost line of the specified length with the first point fixed in the document window. Since the document window became activated upon selecting the point, the predefined input mode is back On: the next field has become focused on in the Properties bar — **Angle**. Enter the angle value. It will be entered in the **Angle** field. Press **<Enter>**. The angle value and the line itself will be fixed.

You do not have to specify the start point of a line after entering the length. This can be done either before defining the length, or after defining the angle.

If for some reason you need to specify the line's inclination angle first, and then its length, do the following.

1. Call the **Line** command. Without exiting the predefined entry mode, i.e., without entering the length value, press **<Tab>**.

The focus will switch from the **Length** field to the next predefined field — the **Angle**.

Since the Properties bar activates upon inputting the value of the predefined parameter, then pressing the **<Tab>** key or the **<Shift>+<Tab>** key combination activates at this moment the next or the previous control on the Properties bar.

2. Enter a new value and press the **<Enter>** key.
The angle will be fixed, and the focus will automatically switch to the **Length** field.
3. Enter a new value and press the **<Enter>** key.
The line will be fixed.

Switching between the Properties Bar and the Document Window

The document window becomes active immediately after you execute the command to create a graphic or 3D object, meaning that the system waits for you to specify the object parameters by clicking points or existing objects.

The part's Properties bar becomes active at the time of switching to defining the object parameters by the Properties bar. This happens when:

- ▼ entering values in the predefined fields (see the previous section),

- ▼ activating the Properties bar control by the mouse or an accelerator key,
- ▼ clicking the mouse on a free space on the tab,
- ▼ switching between tabs by clicking on a tab tag.

Note that the Properties bar does not activate when clicking its title, using its context menu, clicking any other button on the Advanced Control panel or using the geometrical calculator.

When the Properties bar is active, switching to the document window occurs when:

- ▼ the *<Enter>* or the *<Esc>* key is pressed,
- ▼ clicking the mouse in the window,
- ▼ switching to another Windows application window.

1.4.2.5. Entering Values in the Properties Bar Fields

To explicitly define a parameter value in a field of the Properties bar, click the left mouse button in that field. It will become editable. Enter the desired number.

Another way to access a parameter field is pressing the *<Alt>* key and another key corresponding to the underlined letter in the parameter name (for example, *<Alt>+<E>* to enter the line inclination angle).

The numerical parameter values of the graphical objects can be “read” from the existing objects by means of the geometric calculator (see Section 3.1.2 on p. 871). Note that calling the geometric calculator on a parameter field is possible if this field is **not active**.

In the Properties bar fields you can enter not only the numerical values of the parameters but also the expressions for their calculation. Syntax of expressions is described in detail in Section 7.1.3.3.1 on p. 1580.

If an expression begins with the *<^>* symbol, for example, *^5+M_PI*, the expression calculation result will be added to the value contained in the field prior to entering the expression.

After entering an expression, press *<Enter>* to calculate it.

The described methods can be used for parameters in different states: fixed, active, auxiliary (see Fig. 1.4.5 and Table. 1.4.2 on p. 86).

When jumping to the next parameter, the value of the current parameter is automatically fixed.

The numerical values in the Properties bar fields are displayed with the precision defined in the ‘Number Scheme Setup’ dialog (see Section 9.1.2.2 on p. 1668). This precision does not affect the parameter value stored inside the system — it is always equal to the number specified by the user.

Setting the cursor in a field with an already defined parameter and pressing the *<Enter>* key means a repeated input of this parameter value. At the same time, the system stores the value that was displayed at the moment you pressed *<Enter>*, meaning that the number is stored with the number of decimal places displayed.

1.4.2.6. Fixing Parameters

Fixation is possible for all the numerical parameter values of the graphical objects and the point coordinates of 3D objects.

Value of fixed parameter stays constant, other parameters become available for modification. The indication of a fixed parameter is a cross displayed on the switch next to the parameter field (see Fig.1.4.5 and Table 1.4.2 on p. 86).

Parameter fixing can be viewed as limitation of the possible configurations of the object being created.

Suppose you need to draw a line whose length should be exactly 60 mm. Fix the line start point, and then enter the value 60 in the line length field and press the *<Enter>* key. Now, upon any cursor movements, only the line inclination angle will change, while the length will remain equal to 60.

Notably, when you specify a point on the working field or remove a parameter of an existing object (see Section 3.1.2 on p. 871), this parameter becomes fixed automatically.

If, while moving the cursor, you reach a desired value of any parameter and want to fix it, without moving the mouse activate the parameter field using the relevant keyboard shortcut (for example, *<Alt>+<E>* for the line slope angle) and then press *<Enter>*.

1.4.2.7. Releasing Parameters

To cancel the fixation of a parameter value, left-click the switch next to the parameter name. The fact that the fixation has been canceled is indicated by the absence of a cross on the relevant switch (see Fig. 1.4.5 and Table 1.4.2 on p. 86).

Assume that while drawing a line you specified the start point and then entered and fixed the length value equal to 60 millimeters. After that, upon any cursor movement, only the line inclination angle changed. If you now release the line length, then you will be able again to vary either the inclination angle or the length.

While creating an object, you can repeatedly fix or release its parameters.

1.4.2.8. Activating Parameters

This method is accessible in graphic documents when constructing the following objects: arbitrary, parallel and perpendicular line segments, circles by two points, by three points, tangent line to one curve, arcs.

Parameters defined by fixing the cursor at a certain point within the document (for example, point coordinates, start and end angles of an arc) may be activated.

When defining such parameter, a “check mark” is displayed on the parameter’s switch, meaning that the parameter is active (see Fig. 1.4.5 and Table 1.4.2 on p. 86), i.e., the system expects a value to be input for this particular parameter. After you specify the value, a parameter becomes fixed, and the next parameter becomes active.

When creating objects, their parameters become active in the order set in the system by default. However, the user can change it if necessary.

To activate an object parameter, click the left mouse button on its name (not on the switch, nor in the input field!). The parameter will become active, and you will be able to specify its value.

Suppose, you need to create a line with a specified length, parallel to another one and ending at a given point. Call the parallel line creation command, select the current line, enter the line length and fix it. By default, the point that you select in the document field will be treated as the start point of the line, therefore currently “checked” is the **p1** parameter. To be able to select that same point as the end point of the line, activate the **p2** parameter by clicking the mouse on its name. The check mark on the switch of parameter **p1** will disappear, appearing on the switch of parameter **p2**; the ghost of the line being entered will rotate by 180°. Now specify the line end point, for example, executing the snapping to the required point.

You can activate both the auxiliary and fixed parameters (for example, when editing objects). In this case, the activation of a parameter is identical to releasing its value.

1.4.2.9. Saving Parameters

Quite often you need to draw several objects with a number of identical parameters. A typical example is concentric circles (their identical parameter is the center point coordinates).

KOMPAS-3D allows memorizing parameter values and using them before the **current command is completed** when creating the next objects.

Perform the following actions to use identical parameters while creating objects.

1. Specify the parameters that have to be memorized.
2. Click the **Remember Status** button or press the `<Ctrl> + <Shift> + <P>` key combination. The button will stay pressed, indicating that the parameter is remembered.
3. Keep constructing as long as the remembered parameters are needed.
4. Click the **Remember Status** button.

If the entered parameters uniquely define the object (for example, an already fixed center point and circle radius), then the **Remember Status** button will become inaccessible.

You can memorize parameters when completing various operations. Below are several examples of how this functionality can be used. After reviewing them, try to create the following object groups:

- ▼ concentric arcs with an identical opening of the angle,
- ▼ same-length lines with the same start point,
- ▼ same-length lines parallel to the same object,
as well as perform the following actions:
- ▼ make identical the radii of several circles and arcs,
- ▼ measure the length of several sections of a curve starting at the same point.

Example 1. Concentric Circles

1. Click **Tools — Geometry — Circles — Circle**.
2. Specify the circle center point.
3. Click the **Remember Status** button.

4. Now subsequently select the points lying on the respective circles.

If the **Auto Create Object** button on the Special Control panel is pressed, the circles will be created automatically. Otherwise, you will have to confirm the creation of each circle by clicking the **Create Object** button.

The automatic and manual object creation is detailed in Section 1.4.2.10 on p. 93.

If you unfix the center coordinates and then select another center point, you can create a new family of concentric circles.

Example 2. Placement of Several Points on a Single Vertical

1. Call the command **Tools — Adding Constraints — Points — Align Handles Vertically**.
2. Select the first point for a symmetric constraint.
3. Click the **Remember Status** button.
4. Sequentially specify the remaining points to be aligned.

Example 3. Measuring the Distance from one Point to Several Others

1. Call the command **Service — Measure — Distance between 2 Points**.
2. Specify the point from which you want to measure the distance.
3. Click the **Remember Status** button.
4. Sequentially specify the points to which you want to measure the distance.

The values of the measured distances will appear in the info window.

1.4.2.10. Automatic and Manual Object Creation

When you modify object parameters while constructing an object, sometimes you will not need to create an object immediately after specifying all defining parameters. It is convenient to decide first whether the parameter values are correct, and only after that to confirm the object creation.

Two buttons are displayed after you execute the majority of the object entry commands on the special control panel (see Fig.1.2.2.1 on p. 52).

One of them, **Object Auto Creation**, is pressed by default. While it is in pressed state, all objects are created (fixed) immediately after you enter parameters sufficient for constructing it. The remaining parameters of the object will retain current values. For example, in order to create a circle, it is sufficient to set the center's position and a point on the circle. Therefore, if autocreation is enabled, the circle is fixed in the document after specification of two points. Presence of axes depends on the switch enabled in the **Axes** group. Thus, in order to create a circle with axes, ensure that axes drawing is enabled prior to center and point on the circle setting. If it is disabled, enable it.

If there is no need to create objects automatically, release the **Autocreation** button. Now, to confirm the creation of every subsequent object, you will additionally have to click the **Create Object** button. Until this button is pressed, the object is not fixed, so you can modify any object

parameter (see Section 1.4.2.8 on p. 91) any number of times. In the example above, it was possible to enable/disable circle axes both prior to and after specification of points. Each modification will be immediately reflected in the object ghost in the document window, helping you to make sure you are entering the correct values.

You can also call the **Autocreation** command (and, respectively, enable/disable autocreation of objects) using the `<Ctrl> + <Shift> + <Enter>` key combination.

The automatic creation is not provided for some graphic objects (for example, equidistant). You have to fix them manually.

To fix a graphic object, you can simply click it.

When describing commands for construction of objects for which auto create is supported, it is implied that it is enabled. The cases when autocreation should be disabled are specifically mentioned.

1.4.2.11. Reselecting Objects

When executing numerous commands, you are required to select an object that will be used as a reference object for construction.

Once you have selected an object, you can create several objects on its basis.

To select another object as the reference object and create a new group of objects, click the **Reselect** button or press the `<Ctrl> + <Shift> + <Z>` key combination. The constructed objects will be fixed, and the system will wait for you to select a reference object again.

You can use this button to construct several groups of lines parallel or perpendicular to a specific object, several groups of angular dimensions from a common datum, etc.

Another purpose of the **Reselect** button is reselecting the reference object without repeating the command.

For example, if you accidentally specified a wrong curve for constructing a tangent arc, click the **Reselect** button. The selected curve will be unselected, and the system will wait for you to specify another reference object.

1.4.2.12. Copying object properties

Sometimes, you may need a new or edited object has a number of properties similar to a previously created object. When working with graphical documents and sketches, it is possible to copy some properties of an existing object without leaving the creation or editing process.

The properties are copied according to the following rules:

- ▼ The **Current Line Style** property is copied among all objects allowing the change of a line style (for example, a circle line style can be copied into a line, equidistant line, wavy line, a brace, etc.).

- ▼ The properties **Text Style**, **Font Options** and **Paragraph Properties** are copied among all objects that contain text and allow changing of these properties.
- ▼ Some properties are copied only between objects of the same type (e.g. leader arrow view can be copied to another leader only and not to a dimension).

Object properties are copied using the **Copy Properties** command. The **Copy Properties** command is available in the Special Control Panel after calling most of the commands located in **Geometry**, **Dimensions**, **Designations**, and **Designations for Construction** bars.

In order to copy an object's properties:

1. In the Special Control Panel, click the **Copy Properties** button or select the **Copy Properties** command in the context menu.

The cursor will change its appearance.

2. Specify the object to be the source of properties being copied. For this purpose, hover the cursor over the object whose properties should be copied. When the selected object highlights, click the left mouse button.

The system will automatically return to the command from which the **Copy Properties** command has been called.

3. Specify the parameters of the new or edited object.
4. Finish creating or editing the object.

The object will have the properties of the source object.

The **Copy Properties** command can be interrupted before returning to the command from which it has been called using one of the following methods:

- ▼ Click the **Interrupt command** button the Special Control Panel,
- ▼ Call the **Interrupt command** command from the context menu.
- ▼ Press the <Esc> key.

The **Copy Properties** command can also be called using the <Ctrl>+<Shift>+<C> key combination.

1.4.2.13. Displaying Object Parameters Next to the Cursor

When you create and edit geometric objects, their parameters can be displayed not only in the Properties bar fields, but also next to the cursor (Fig.1.4.8) This helps control the correctness of the construction.

Fig. 1.4.8. Displaying object parameters next to the cursor:
a) when creating an arc using three points, b) when creating a line parallel to an existing line

The command parameters display is controlled by the **Display Commands Parameters** option (see Section 9.1.7.1 on p. 1703) in the cursor parameters setup dialog.

1.4.2.14. Rounding Parameter Values

When working with KOMPAS documents you can turn on the rounding of linear values. This function is used in various commands creating and editing graphical and three-dimensional objects.

The enabling and the switching off the Rounding mode in the current document window (windows) is done by the **Rounding** button on the **Current Status** bar or by the <F7> key.

The default setting of the rounding mode (On or Off) for new document windows is done in the Cursor Properties dialog (see Section 9.1.7.1 on p. 1703).

When On, the parameter values are rounded to the nearest value — a multiple of the cursor current step. The value is rounded to the smaller one if the difference between the value and the nearest multiple is less than half the cursor step; otherwise it is rounded to the greater one.

Let's review working in the rounding mode in detail based on a rectangle creation example. For this, do the following.

1. Make sure the rounding mode is turned off.
2. Set the cursor step equal to 5 mm.
3. Call the **Rectangle** command.
4. Specify the first rectangle's vertex position.
5. Move the cursor and watch the values in the **Height** and **Width** fields on the Properties bar.
6. You will see that these fields display decimal values with an accuracy of up to four decimal places.
7. Click the **Rounding** button.
8. Make sure the **Height** and **Width** fields now display integer values multiple of 5, i.e., the rectangle dimensions change in increments with the step equal to the cursor step.
9. Change the cursor step from 5 to 2.
10. Make sure the rectangle's dimensions became a multiple of 2.

Note that the rounding mode is temporarily suspended when a snap activates. For example, if the end point of a line segment being constructed is specified by some kind of a snap, say, **Nearest Point**, then the line length will not be rounded. It will be exactly equal to the distance from the start point to the point of the snap.

Additionally, no rounding of the fixed parameter values is done. For example, when constructing a line segment parallel to a given one, you can enter any value in the **Distance** field on the Properties bar and fix it. When selecting the start and end point of a line, its length will be rounded, while the distance to a reference will not.

The rounding of values when working with three-dimensional objects takes place when “dragging” their defining points. Note that in parts and assemblies it is possible to round not only linear but also angular values.

2. Three-dimensional modeling

2.1. General information

2.1.1. 3D Modeling Main Definitions

2.1.1.1. Model in KOMPAS-3D

KOMPAS-3D supports creating two **types of models**: part and assembly.

- **A Part** is a model type designated for presentation of products manufactured without assembly operations. Is created and stored in a document «Part», a file extension— *m3d*.
- **An Assembly** is a model type designated for presentation of products manufactured with assembly operations. Is created and stored in a document «Assembly», a file extension— *a3d*. Technological assembly is a variety of an assembly. Is created and stored in a “technological assembly” document: file extension — *a3d*.

Three-dimensional model in KOMPAS-3D consists of **objects**. Objects are divided into:

- geometrical,
- layout elements,
- measurement objects,
- components.

Geometrical objects include: bodies, surfaces, curves, points, sketches, construction geometry objects. Layout elements include dimensions, cosmetic thread, leader lines, surface finish symbols, datum symbols, positions, position reference numbers, shape and position tolerance symbols.

A Component is an object of a model which, in its turn, is a model: part or assembly.

Model objects are created and edited by performing **operations**. During object creating and editing its associative linking with other object is possible. An **associative relation** is a one-way dependence of an object's position or geometry on another object's position or geometry. The dependent object is considered **derivative**, while the object on which the derivative object depends, is considered to be a **source object** with respect to the derivative one.

You can assign MP calculation parameters to a model as a whole, or its parts (bodies, components)—material and material density, as well as you can assign **properties**—data about the product that the model (part of the model) represents.

Model contents, sequence of its construction, and relations between model objects are displayed in the **Design Tree**.

2.1.1.2. Model objects

2.1.1.2.1. Geometrical Objects

Geometrical objects consist of **primitives**. Primitives are:

- vertex,
- an edge,
- face.

Vertex— primitive, being a kind of a point or end of edge. Special vertex case is a zero length edge (for example, cone vertex)

An edge is a primitive representing a section of a curve or border line of a face limited by vertices and containing no other vertices inside. In special cases, an edge may not be limited by vertices (closed edges).

A face is a primitive representing a surface's part or a surface limited by edges and containing no other edges in it. In special cases, face may not be limited by edges (for example, spherical and toroidal faces).

Such objects like planes and axes do not have primitives.

Other objects, depending on their type, consist of one or several primitives. For example, object “point” consists of one vertex, polylines and sketches— of edges and vertices, bodies— of edges, vertices and faces.

Body is a model object having a certain volume and related to a material. A body does not have a separate file that represents it.

As a rule, body is a set of faces, edges and vertices. In special case, body may be represented as one face (for example, spherical or toroidal bodies).

Body faces form closed surface. The closeness failure results in the breach of the body's integrity.

Body construction in a model is described in Section 2.3.

Specific body type— **sheet bodies**. They are provided for modeling parts obtained from the sheet material using bending operations. Sheet body constructing is described in Section 2.4.

Surface is a geometric object represented by a coherent sum of faces or by one face. Faces of a surface cannot be faces of other objects (other surfaces and bodies).

Constructing surfaces is described in Section 2.6.

A sketch is a 3D model object created using the drawing graphical editor on a plane or on a flat face.

Sketches are used in some operations. For example, a sketch may shape a section of a body resulting from the extrusion operation, rib contour, etc.

Requirements to a sketch are defined by an operation in which it is used.

Drawing sketches is described in Section 2.2.

Construction geometry objects are:

- coordinate systems,

- coordinate and auxiliary planes,
- coordinate and auxiliary axes,
- control points,
- attachment points.

Constructing auxiliary geometric objects in a model is described in Section 2.8.

2.1.1.2.2. Layout Elements

Layout elements are:

- cosmetic thread,
- dimensions:
 - linear,
 - angular,
 - diameter,
 - radial,
- designations:
 - surface finish symbol,
 - Datum symbol,
 - leader
 - ref.No. leader,
 - shape and position tolerance symbol.

Constructing layout elements in a model is described in Section 2.9.

2.1.1.2.3. Measurement objects

Measurement object— an object containing measurement operation results.

Measurement objects are:

- distance and angle,
- edge length,
- area.

The measurement object value always corresponds to actual value of the model's measured parameter.

Making measurements in a model is described in Section 2.15.2.

2.1.1.2.4. Components

Component is an object of a model represented by another model saved in a separate file. Components include parts, assemblies, standard products and library elements. Local part is a special component type. A local part has no individual file representation and is stored within its model. Components, in turn, can consist of other components, etc.

One and the same component can be inserted in different models. You can insert one and the same component twice in a model.

Operations that imitate processing an assembled product, e.g. create a hole that passes through several components, can be performed within a component-containing model. The result of such operations is not passed to the component files.

Components can be linked by **matings**. Two types of matings are available:

- positioning matings fix an object with respect to another object in a certain way,
- mechanical matings define the law of how one object moves relative to another.

For details about adding components to a model and applying matings to them see Section 2.11.

2.1.1.3. Modes of working with a model

KOMPAS-3D offers special modes for working with 3D models. (Table 2.1.1). To enable and disable these modes, buttons of the **Modes** bar are used. Another exception is sketch mode and on-the-spot editing mode—their buttons are found on the **Current status** panel, and model section mode—its button is found on the **View** panel.

Tab. 2.1.1. Modes for working with models

	Name	Purpose	Specifics
	Sketch mode (see Section 2.2.1.2)	Creation of a new sketch or editing an existing sketch.	Commands for creation of geometric objects and dimensions are available.
	The mode for displaying a model in the perspective projection (see Section 2.1.3.5)	Displaying a model taking account of the perspective.	The degree of the introduced image perspective distortion can be adjusted.
	Surface smoothness test mode (see Section 2.15.4)	Visual assessment of smoothness of faces' joints, as well as identification of minor curvature changes inside the faces.	All faces of a model are presented as mirroring the specified image. The image's type can be customized.
	Model section mode (see Section 2.15.5)	Visual assessment of mutual position of parts and nodes of an assembly model, a part's design elements, its wall thickness, etc.	Model is displayed by a truncated intersecting plane or a set of planes. In operations in this mode you can specify vertices, edges, and faces of the model, including truncated, but you cannot specify vertices, edges, or faces of a section.

Tab. 2.1.1. Modes for working with models

	Name	Purpose	Specifics
	The mode for presentation of a sheet body in the fully fledged form (see Section 2.4.7.2)	Displaying bends, selected by the user, in the bent form, while other bends are displayed in the open form.	Only the following actions can be performed: <ul style="list-style-type: none"> – model viewing and printing; – modifying geometric and mass center characteristics of the model.
	Assembly component separation mode (see Section 2.15.7)	Displaying assembly component in the exploded form (this may be needed for a more intuitive appearance of the assembly).	Only the following actions can be performed: <ul style="list-style-type: none"> – model viewing and printing; – creation of reports.
	The mode for editing a component at place (see Section 2.11.6.2.1)	Editing the selected component in the current assembly window, surrounded by other components.	All construction and editing commands affect only the selected component. Other assembly components are shown in the window, but not accessible for editing, they can be used when executing commands (selecting faces, edges, vertices).
	The mode for recalculation of model's dimensions with tolerances applied (see Section 2.10.3)	Recalculation of model's dimensions taking account of the assigned tolerances. Dimensions of a model are calculated in accordance with the current recalculation (see Section 2.10.3.1).	Only the following actions can be performed: <ul style="list-style-type: none"> – model viewing and printing; – modifying geometric and mass center characteristics of the model. – creation of reports.
	The mode for displaying dimensions of a selected element (see Section 2.9.2.2.2)	<ul style="list-style-type: none"> – Viewing an object's (sketch or operation) dimensions outside the process of its editing. – Modifying object dimensions' values. 	Once an object is selected, its dimensions are displayed on the screen – dimensions of sketches and operations expressed in linear and angular values.

2.1.1.4. Base point of a three-dimensional object

Base point of a 3D object is a point to be used as the origin for construction of an object's geometry in a model. The base point position is determined by the system automatically and depends on the object's type and method of construction. For example, the base point of a component is the starting point of its absolute coordinate system while the base point of an operation built on a sketch is the center of gravity of the sketch curves.

The base point is represented on the screen as three mutually perpendicular vectors.

For example, the base point is displayed when a copied object for an array creation is selected (Fig. 2.1.1).

Fig. 2.1.1. Examples of displaying the base point of a 3D object:
a) a component's base point; b) base point of the extrusion operation built on a sketch

2.1.2. Model tree

During operations with any part or assembly, a window with a **Model Tree** may be displayed. This window is always positioned inside the model document window.

The window contains two tabs – **Construction** and **Versions**. The **Construction** tab displays the model's Design Tree. It is described in this section. The **Versions** tab displays the model's Tree of Versions. The tab is described in Section 2.13.1.2.

The model's Design Tree (hereafter – the Design Tree) is a graphical representation of an object set making up the model. Root object of the Design Tree is the model proper, i.e. a part or an assembly. Object icons automatically appear in the Design Tree right after such objects are created in the model. Section 2.1.2.5).

Model and assembly components may be located in the Tree in the order of their creation (see Section 2.1.2.1) or be combined by types and groups (see Section 2.1.2.2).

Components of a model—parts and subassemblies—are independent models. Therefore, their constituent objects are also placed in the relevant tree branches.

There is a control panel with four buttons in the top part of the **Construction** tab (Table 2.1.2).

Tab. 2.1.2. Buttons of the **Construction** tab toolbar

Name	Description
	Model structure display Controls method of data presentation in the Design Tree. If this button is enabled, the model structure is displayed in the tree window (see section 2.1.2.2); if the button is disabled, the tree window displays the model construction sequence (see section 2.1.2.1).
	Components of the Model tree Allows to specify which types of items will be displayed in the Design Tree, and which will be omitted. You can also enable component grouping for assemblies (see Section 2.1.2.3). Adjustment of structure is only enabled when the Model structure display button is selected.
	Relations Controls the special area display in which hierarchy of relations is shown for the object selected in the Design Tree (see Section 2.1.2.7.2). The area is displayed in the lower section of the Tree's window.
	Additional tree window Allows to create additional Design Tree window and to display the section or item which had been selected in the tree before pressing this button (see Section 2.1.2.4).

The Design Tree is intended not only for item fixing, it also facilitates selecting and specifying items during command execution (see Section 2.1.4.1.5).

Icon size in the Design Tree can be customized, see Section 9.1.3.8.7.

Context menus of items and sections of the Design Tree contain the most frequently used commands, such as: commands for item display control, commands for item inclusion in/exclusion from calculations, commands for editing, deletion etc.

The tree may contain additional information about the model represented as special icons used for marking objects. The list of such icons and their descriptions are given in table 2 Appendices I.

All commands of the section context menu, excluding the **Attributes** command, are applicable for all items included in the section.

The **Design Tree** may be hidden. To do this, call the **View – Model tree** command. To enable displaying of the window, call the command again. In the enabled state, a “checkmark” is displayed next to the command name in the menu.

The **View – Model tree** command controls only the main window display of the Tree. Additional Tree windows, if any, have to be closed manually.

If several windows are open with the same model document, then the **Design Tree** can be shown or hidden in any of them. Different sets of additional Tree windows may also exist in different model windows

2.1.2.1. Display of model design sequence in the Design Tree)

Stages of the model's construction are displayed in the Design Tree, if the **Display model's structure** button is disabled. The button is located in the toolbar of the **Construction** tab in the **Model Tree** window. Model objects are displayed in the Design Tree in the order of their creation (Fig. 2.1.2).

Fig. 2.1.2. Model creation sequence

The following features are accessible for operations with the Tree reflecting model creation sequence:

- Changing creation sequence (see Section 2.14.3.6.3),
- Use of creation finishing pointer (see section 2.1.2.6).

2.1.2.2. Display of model structure in the Design Tree

The model's structure is displayed in the Design Tree, if the **Display model's structure** button is disabled. The button is located in the toolbar of the **Construction** tab in the **Model Tree** window (Fig. 2.1.3).

The model's structure is a set of sections into which model's objects are grouped by types. These sections are displayed in the Design Tree. Each section of the Tree has a name and an icon.

A Design Tree section is a named part of the Tree containing model objects of the same type, for example, **Sketches**, **Bodies**, and so on.

Items inside sections are positioned in order of their creation. The section names, their icons and types of constituent objects are given in Table 1 of Appendix I.

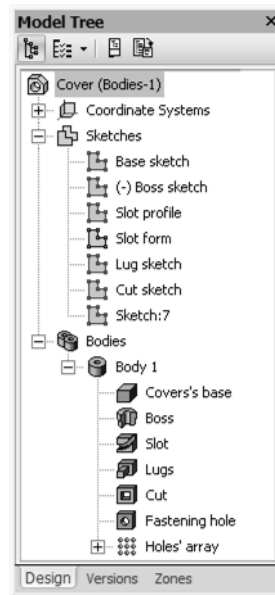

Fig. 2.1.3. Model structure

Such items as *Surface Splitting*, *Delete faces*, *Surface Knitting* may be located in section *Surface* or *Body* depending on what they refer to. For example, splitting operation of body surface is placed in the section related to this body, while surface splitting operation—in the *Surface* section.

The items which belong to several bodies, to a body and surfaces, or to a body and a component simultaneously, are located at level one of the Tree (i.e., a Chamfer object applied to body and surfaces; a Hole object applied to a body and to a component).

Additionally, some error operations are displayed at level one of the Design Tree (for instance, the operations containing an “Undefined Operation Applicability Range” error).

Objects may be duplicated in the Design Tree:

- Items included in macro elements are located in their places and in “*Macro*” section
- the surfaces which formed the body as a result of the “*Surface Knitting*” operation are located in section “*Surfaces*” and in the section related to the body.

The user can setup the Design Tree's composition by enabling and disabling sections' visibility; for assemblies, it is also possible to set up splitting components into the following groups: *Assembly units*, *Parts*, *Library components* and so on (see Section 2.1.2.3).

The Fig.2.1.2 shows display of creation sequence for the same part whose structure is provided in Fig. 2.1.3. In other words, these Figures demonstrate different representations of the same model in the Tree.

Model can include identical components. For example, creating a pattern enables creation of several identical components. Identical components form a branch in the *Components* section or in a group, if grouping is enabled. The branch name is formed according to a template. *<Component Name> (xN)* where N is the total number of identical components. Displaying of components grouped by types is illustrated in Fig. 2.1.4.

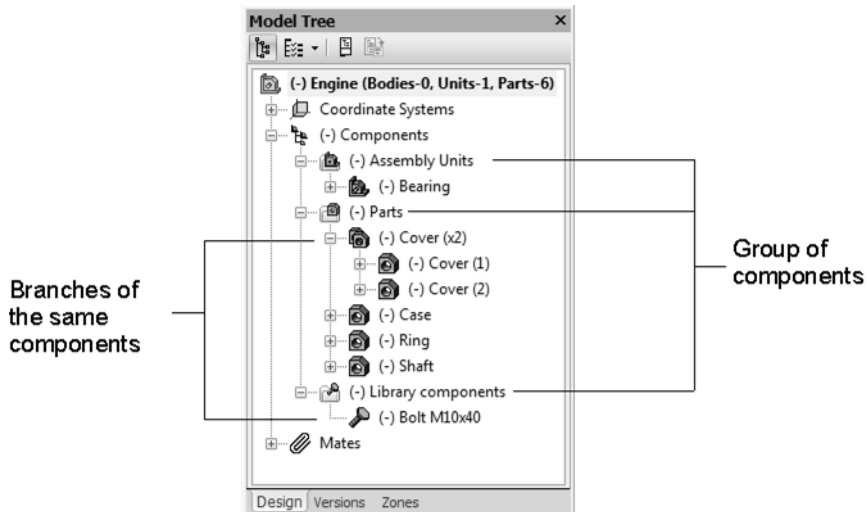

Fig. 2.1.4. Assembly structure with the display of groups

2.1.2.3. Setup of Design Tree display

You can enable and disable display of sections or component groups on the Design Tree, as well as select a default information presentation method, i.e. model structure or model creation sequence.

The **Model Tree Structure** button is located on the toolbar of the **Construction** tab, the **Model Tree** window; you can use this button to customize the default structure of the Design Tree and choose the Tree type to be saved.

This button is available if the **Display model structure** button is enabled in the toolbar of the **Construction** tab.

The setup dialog, which is described in Section 9.2.7.4.12, appears after the **Model Tree Structure** button is clicked.

Clicking the triangle on the right of the **Model Tree Structure** button expands the menu of this button which contains commands corresponding to sections' names (Fig. 2.1.5). To turn on/off the section display in the Design Tree, call the respective command.

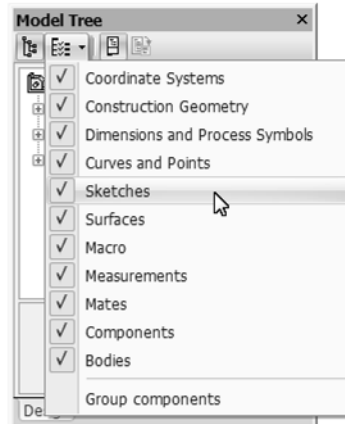

Fig. 2.1.5. Tree content setup

You can use the **Group components** *command* to divide the Design Tree's components into groups depending on type — Assembly units, Parts, Library components, and so on.

A tick on the left of a command's name means that displaying of the respective section or component grouping is enabled; if there is no tick, it is disabled.

Empty sections and groups cannot exist in the Tree. Therefore, the sections displaying of which is enabled or groups will appear in the Tree only after the first relevant item of this type has been created in the model. For instance, if a model does not have a single sketch, there will be no *Sketches* section in the Tree.

The objects in a disabled section remain in the model window (if their display is not disabled manually).

If a model is opened in several windows, the setting up of the Tree contents made in one of them is applied to all the windows the model is in.

2.1.2.4. Optional window of the Design Tree

Optional Design Tree window is a special window in which a part of the Tree is displayed (i.e. an object, a section, or relations). For instance, Fig.2.1.6 shows an optional window of the Design Tree which displays the "Sketches" section.

Fig. 2.1.6. Sample optional window of the Design Tree

In order to create an additional Design Tree window, in which an object or a section will be displayed, and click the **Additional Tree window** button on the control

panel of the Design Tree. Description of the Tree's additional window for an object or section can be found in this section.

In order to create an additional window of the Design Tree, select the required object in the Design Tree or in the model window and call the **Relations in Additional Window** command from its context menu. Viewing relations in the window is described in Section 2.1.2.7.2.

A copy of the selected part of the Design Tree is displayed in the additional window for the object or section. The header of the additional Tree window contains the name of the object/section shown in the additional window.

Changing the information presentation method in the Design Tree as well as Tree content does not influence the Tree optional window content. They can only be affected by changes in the model concerning the object/section that is being shown in the additional window.

For example, when the model structure was shown in the Tree, an additional window containing section "Sketches" was created. After this, the display of section "Sketches" in the Tree was disabled. The additional window still displays section "Sketches" with its content. Then, structure display was disabled in the Design Tree, which also disabled object grouping by section and displayed all the objects in the order of their creation. The additional window still displays section "Sketches" with its content.

Creating a new sketch in the model will cause a new object to appear in the additional window with section "Sketches". Deleting, hiding or excluding a sketch from the calculations will also be shown in this additional window.

If you delete the object (or all objects in the section) that is shown in the additional window, the window will be closed automatically.

The same object context menus are available in the additional window as in the Design Tree. Using these menus you can quickly call frequently used commands, e.g., Edit Object or Delete Object. Selecting an object in an additional window is equal to selecting it in the Design Tree.

The set of additional windows is remembered by the system before closing the model window, in which they were created. If you open this model again, as well as if you open it in a new window, additional windows of the Design Tree will not be available.

Additional windows of the Design Tree are useful while arranging quick access to frequently used model objects — sketches, construction geometry, etc.

For instance, by enabling model structure display in the Tree, you can create optional windows with "Sketches" and "Auxiliary geometry" sections. Later, you can disable displaying these sections in the Design Tree to shorten it or enable the model creation sequence in the Tree if it is more convenient.

If there are several additional Design Tree windows in the model window, the following location variants are recommended for them to use the screen area more rationally:

- Fix all additional windows at one of the borders of a document window and minimize them
- Fix all additional windows at one of the borders of a document window in such a way as to create a single bar.

2.1.2.5. Names and icons of items in the Tree

The name of each object can be entered during its creation. By default, it is assigned to objects automatically depending on their type (*Part*, *Assembly*, *Assembly unit*, *Body* and so on) or method of their creation (*Axis through edge*, *Rotation operation*, *Chamfer*, *Coaxiality (Cap – Gasket)* and so on).

Names of parts and subassemblies are taken from files of those components.

Many items of the same type can exist in a model. For recognition purposes, a sequential number of the given item type is added automatically to item names which were assigned by default. For instance, *Fillet:1* and *Fillet:2*, *Trim by plane:1* and *Trim by plane:2*.

You can change the objects' names:

- for the model's root object, components and bodies — using the command for assigning properties of a model, component, body (see Section 5.1.4.1.1).
- for other objects — during their editing (on the **Properties** tab of the Property bar).

You can also rename any object directly in the Design Tree. For this, do the following.

1. Select item name item in the Design Tree.
2. Click on the name selected or press <F2>.
3. Enter the new item name.
4. Click outside the tree items list or press <Enter>.

The new item name will be saved in the Design Tree.

For a model's root object and components, you can enable displaying names consisting of two parts, *name* and *designation* (see Section 9.2.7.4.13). The designation should be set as an object's property to be displayed (see Section 5.1.4.1.1). When renaming an object in the Tree, you can only change its name, not the designation of it, even if it is displayed.

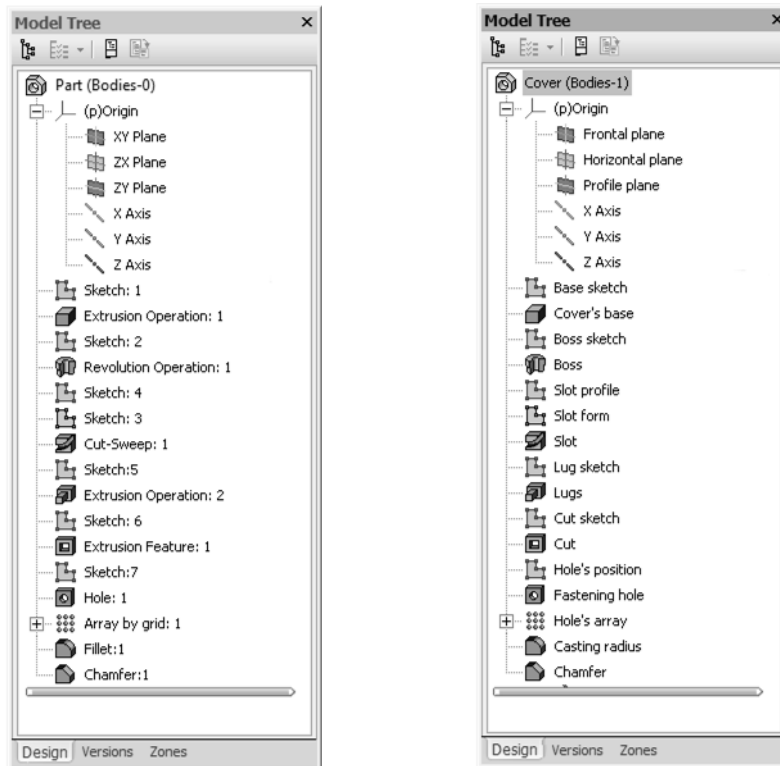

Fig. 2.1.7. Renaming objects in the Design Tree

An icon is displayed to the left of each item in the Tree. It corresponds to the item creation method. Unlike the object name, the icon cannot be changed. Due to this, visual information about creation method remains in the Design Tree after item renaming.

Usually, icons in the Design Tree are displayed in blue. If an object is selected, then its icon in the Tree is green. If an object was selected before executing the operation, then its icon in the Tree is red.

In the Design Tree, objects' icons may contain symbols indicating an object's state. For example, a read-only indication may be added to a component's icon, error symbol and so on. After the object's state changes, the symbol disappears or will be replaced by a different one.

Additional designations are listed in Table 2 of Appendix I.

2.1.2.6. Pointer of model creation finishing

The Model creation finishing pointer is a horizontal line that terminates the Design Tree at the bottom or splits it in two portions.

The pointer of model creation finishing is displayed in the Tree if model creation sequence display is enabled in the Tree (see section 2.1.2.1).

Position of the model creation finishing pointer may be changed. To relocate the pointer, move the cursor to it. As the cursor becomes a two-pointed arrow, press the left mouse button. While holding down the button, move the pointer up or down.

Items which appear in the Design Tree beneath the pointer, will be conditionally deleted. These items and their derivatives will not be displayed in the model window, but the information about them will not be removed from the document. The icons of the excluded elements are displayed in gray color and marked with a “lock” icon in the Design Tree.

Instead of moving the Pointer by the mouse, you may use the **Pointer under selected item** command. The command is called from the context menu of the item selected in the Design Tree.

Moving the pointer by the mouse allows to bring it next to the top border of Design Tree window; however, it can actually be placed only in between operation icons.

Upon every pointer relocation in the Design Tree, the model is updated.

To quickly move the pointer to the end of the Design Tree, you can use the **Roll-back Bar to End of the Tree** command from the pointer context menu.

After the pointer has been moved down, the conditionally deleted model items will be restored.

2.1.2.7. Hierarchy of model objects

Hierarchy of model objects— the order of their submission.

To create any model object, there should be used already existing objects (for instance, to create a sketch, a plane or face is required, to create a chamfer — an edge etc.).

An object, acquiring under its creation certain parts and/or properties of another object, is considered **dependent** to this other object.

For example, the sketch is built on a extrusion feature face — then, the sketch is dependent on the feature. A sketch contains projections of edges of the forming element — the sketch is dependent on this feature. The cut forming element is created by an operation with a sketch — the element is dependent on the sketch. When creating a forming element, its extrusion depth was defined up to a vertex of a rotative element — then the extruded feature is dependent on the revolved feature. A chamfer was created on an edge of a sweep — then the chamfer is dependent on the sweep. The construction axis is drawn through vertices of forming elements — the axis becomes dependent on those elements. The construction plane is drawn through the axis perpendicular to a element face — the plane becomes dependent on the axis and the forming element. This repeats on and on.

There are two types of relations between objects in the KOMPAS-3D model object hierarchy.

- If the object is subordinate to another object, it is called **derived** with respect to the subordinating object.

- If the object is subordinating to another object, then the subordinating object is called **original** with respect to the subordinate.

In certain systems of 3D-modeling the original objects are referred to as “parents”, and the derived objects — “children”.

Coordinate system, existing in the model from the very creation, always is original object (you can create the first sketch and other model objects only on base on it or its elements— coordinate planes) and never shall be the derived object (its parameters do not depend on other objects).

The last object in the Design Tree is never original (since no objects were created after it that could be based on it).

Any other objects can be either original or dependent. The same item can be a derivative and original at the same time but for different elements. For example, a hole is a derivative element of its own sketch and an original element for a chamfer created on that hole’s edge.

An element is always dependent on one or several elements that are above it in the Design Tree, and can be a parent to one or several elements, which are below it in the Design Tree.

However, this rule does not uniquely define relations between particular objects. Object position does not allow you to judge, which of them is original and/or derived with respect to this object.

If necessary, you can view relations of any objects in the model (see Section 2.1.2.7.2).

2.1.2.7.1. Hierarchical relations between the objects

Hierarchical relations between model elements are an inseparable part of this model. User can not refuse to make these relations or delete them.

Relations occur in the course of model object creation and will persist unless those objects are deleted or edited. Hierarchical relations are maintained through any model changes.

For example, when creating a sketch on a feature face, the hierarchical relation between sketch and face is created. As a result, this sketch will stay on its “home” face through any changes to the model (up until deleted or moved to another face).

Any item is involved in hierarchical relations together with its original and derivative elements. Relations have the following properties:

- At changing the parent object the derivative one changes too
- The derivative object can be changed both by editing of the source object and by changing own, independent parameters of this derivative object.

2.1.2.7.2. View of Objects Relations

To view relations involving a particular object, press the **Relations button** on the toolbox of the Design Tree. The relation view window shall appear at the bottom

part of the Tree. Then select the object needed in the Design Tree or any part of it (e.g. face of a shape-generating element) in the Model window. In the relation view area the information on the hierarchy of relations for the selected object will be shown (Fig. 2.1.8).

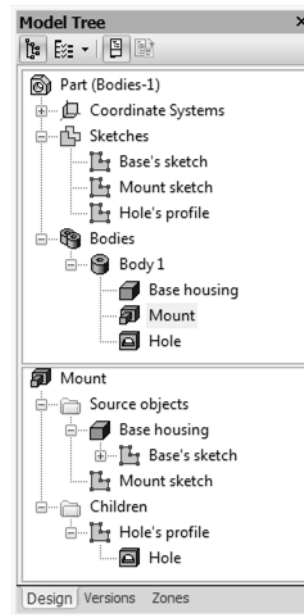

Fig. 2.1.8. View of hierarchy

The first line of the relations area shows the name of the element whose relations are considered.

The two sections subordinating to shown element display elements belonging to the described element's hierarchy as structured lists. Sections in these lists can be expanded and collapsed by clicking the mouse on the "+" and "-" signs next to their names. To view long lists, you can use scroll bars.

The **Source objects** list displays source objects, the **Children** list — resulting ones. The names of objects in the relation window are the same as their names in the Design Tree (if you entered new names of elements instead of the generated by default, these names will be shown in the relation window).

First level of **original** object list contains elements directly subordinating the current one. If these elements are in turn dependent on other elements, then the next layer of the list contains their original elements.

First level of original object list contains elements directly **subordinating** the current one. If these elements are in turn parents to other elements, then the next layer of the list contains subordinate derivative elements.

Therefore, the window allows tracking not only direct (explicit), but also indirect (implicit) dependency relations.

The hierarchy of object relations can be viewed in a particular window of the Design Tree (Fig. 2.1.9). To do this, you should select an object in the Design Tree or in the Model window and apply from the context menu the command **Relations in Additional Window**.

Fig. 2.1.9. Viewing of hierarchy in an additional window of the Design Tree

One would commonly need to know an element hierarchy in order to determine what elements changes (editing or deleting) could directly or indirectly affect the given element, and what elements can be affected by changes in the given element.

Let us see an example of definition of hierarchical relations of the object.

Fig. 2.1.8 and 2.1.9 show the element relations hierarchy *Boss*.

Boss, judging by its icon — an attached extrusion element.

What objects are original for *Boss*? To answer this question, let us analyze the structured list **Source Objects**.

At the level of the list, directly following the *Boss*, there are *Boss Sketch* and *Framework Base*. These objects are sources for the *Boss* because they are directly related to it: the sketch has been used for generating the extrusion element, and the framework base — for automatic definition of extrusion depth (to execute extrusion operation, option **To Vertex** has been enabled and the base vertex specified).

Framework Base, to judge by its icon, is an extrusion element. This extrusion element is based on the *Base Sketch* (it is located on the next hierarchic level).

Base Sketch, in its turn, was created on the *Plane XY* (it is located at the list's level, following the *Base Sketch*). *Base Sketch* and *Plane XY* are indirectly related to the *Boss*.

Boss Sketch was created on face *Framework Bases*. That is why the *Framework Base* is located at the level which follows the *Boss Sketch*.

The objects, being original for *Framework Bases*, has been considered above, their list is replicated following *Framework Base*. If the object is original for several other objects, it is (together with its original objects) replicated in the list (perhaps, at different levels) a certain number of times respectively.

Framework Base and its source objects are indirectly related to the *Boss*.

To see the derived objects of the *Boss*, let us analyze the structured list **Children**.

At the level, next to the *Boss*, an icon of the sketch, called *Hole Profile*, is located. This sketch is constructed on the *Boss* face and is indirectly derivative with respect to the *Boss*.

The *Hole Profile* has been used (judging by icon) for generating a cut rotative element — *Holes* (it is located at the list level next after the sketch). *Hole Profile* and *Hole* are indirectly related to the *Boss*.

There are no other objects in the hierarchy *Boss*.

Likewise, you can view hierarchical relations of any object of the three-dimensional model.

Hierarchy of relations is not fully displayed. This indicates that the sequence of model construction has been changed manually.

For example, the model had two extrusion elements, whereas the sketch of the second element was based on the face of the first one. Thus, the second element was derived with respect to the first one. The list of parent objects of the second elements included: its sketch, the first element, the sketch of the first element.

The first element is moved in the Tree to be lower than the second one (which is to be marked in the Tree as erroneous), then it is returned in place (then the error message disappears). As a result, only the sketch of this element remains as the parent object for the second extrusion element.

2.1.3. Model Display Control

2.1.3.1. Scaling, moving, rotating and rotation

You can control model scaling display as well as move, rotate and revolve the model.

If several model windows are open in KOMPAS-3D, each of them may have its own model position and image scale.

In some cases, results of changing model scale and position depend on the spatial location of its circumscribing rectangle. For instance, the model may revolve around the center of its circumscribing rectangle; Upon calling the **Show All** command, the scale of model display will change so that projection of its circumscribing rectangle on the screen surface will fill the model window.

Circumscribing model block is a conditional block whose faces are parallel to coordinate planes and pass through the points of model items which are most distant from each other.

You can select types of items which will be taken into account when creating a circumscribing block. To do this, call the **Service — Parameters... — System — Model editor — Dimensions command** and enable the required options in the appearing dialog.

2.1.3.1.1. Image scaling and moving

To change model scaling display and move, the following commands are used:

– **Move** command (see Section 1.4.1.3),

– Scaling commands (Section 1.4.1.2):

- **Show All**,

- **Scale Up in Frame**,

- **Zoom In/Out**,

- **Scale up**,

- **Scale down**,

- **Show sketch in full**,

- **Scale by selected objects**,

- **Previous scale**,

- **Next scale**.

The image moving command is in the **View** menu and the scaling commands are in the **View— Scale** menu.

The buttons to call the moving command and some scaling commands are on the **View** bar.

To quickly move the image (without calling the dedicated command), you can use **<Shift> + <arrows keys>**. Pressing any of these keys causes image to shift in the respective direction.

2.1.3.1.2. Revolve model

When modeling a part or an assembly, it is frequently required to view it from different sides. To rotate a model you can use:

- **Rotate** command,
- keyboard shortcuts,
- mouse.

Model rotation using the Rotate command

To rotate a model in the window, call the **View – Rotate**. This command allows rotating the model around the center of circumscribing block of the whole model or any of its objects, or around any object of the model. To do so, perform the steps described below after calling the command.

- **Rotate around the center of circumscribing block.**
Press the left button within the model window, the pointer will change—it will transform into a star with two arc-like arrows. Holding down the button, move the pointer.
 - **Rotate around a point** (vertex, center of a sphere).
Move the pointer to the desired object in the model window. As the object gets highlighted and the pointer takes the shape appropriate to the object being selected (see Table 2.1.8), click the left button. Then hold down the left button, and move the pointer (its shape is the same as when rotating around the center of the circumscribing block).
- The direction of rotation around the center point of the circumscribing block or around a point depends on the direction the pointer is moving (Table 2.1.3).

Tab. 2.1.3. Cursor movement dependence of model rotation direction

Cursor movement direction	Model rotation direction
Vertical	In vertical plane perpendicular to the screen surface.
Horizontal	In horizontal plane perpendicular to the screen surface.
By a diagonal	Direction is a resultant of relevant vertical and horizontal components.
Horizontal with pressed <Alt> key	Within the screen plane.

- **Rotating around a straight line** (axis, straight edge, conical or cylindrical face axis, tangent to a curve).
Move the pointer to the desired element in the model window. As the object gets highlighted and the pointer takes the shape appropriate to the object being selected, click the left button. An axis or curve tangent ghost will be displayed on the screen. Holding down the left button, drag the pointer (it has the shape of an axis with two arc-like arrows).
- **Rotate around a perpendicular to a surface** (face, coordinate or auxiliary plane).
Move the pointer to the desired point on the surface and click the left button. A ghost of the perpendicular to the surface in the given point will appear. Holding down the left button, drag the pointer (it has the shape of a plane with two arc-like arrows).
- **Rotate around the center of circumscribing block** (operation, curve, etc.)
Select an object on the Model Tree, then move the pointer into the model window. Holding down the left button, drag the pointer (it has the shape of two arc-like arrows).

To cancel selection of all the objects click **Re-select** on the Special Control Panel.

To exit the rotation command, click the **Interrupt command** or press `<Esc>`.

Rotating a model using the keyboard

To revolve the model around the center of a circumscribing block without calling a specific command, you may use the hot keys (the list is provided in table 2.1.4).

Tab. 2.1.4. Hot keys for model revolution

Hot keys	Direction of revolution
<code><Ctrl> + <Shift> + <^></code>	Up in vertical plane perpendicular to the screen plane
<code><Ctrl> + <Shift> + <v></code>	Down in vertical plane perpendicular to the screen plane
<code><Ctrl> + <Shift> + <right></code>	To the right in horizontal plane
<code><Ctrl> + <Shift> + <left></code>	To the left in horizontal plane
<code><Alt> + <right></code>	Counterclockwise in screen plane
<code><Alt> + <left></code>	Clockwise in screen plane
<code><Space> + <^></code>	90° up in vertical plane perpendicular to the screen plane
<code><Space> + <v></code>	90° down in vertical plane perpendicular to the screen plane
<code><Space> + <right></code>	90° to the right in horizontal plane
<code><Space> + <left></code>	90° to the left in horizontal plane
<code><Alt> + <^></code>	90° clockwise in screen plane
<code><Alt> + <v></code>	90° counterclockwise in screen plane

Model angle of rotation, upon enabling the `<Ctrl> + <Shift> + <arrow keys>` or `<Alt> + <arrow keys>` combination is called **model angle of rotation spacing**. Its value may be adjusted (see Section 9.1.11.5).

Rotating the model using the mouse

If you use a mouse with a scroll or a three-button mouse, you can rotate the model by dragging the pointer holding down the scroll or the middle button.

If the center of the circumscribing block is outside the borders of the screen (usually it happens when you have selected a very large image scale), the closest point of the model to the pointer is used as the center of rotation.

If this is not the case, rotation will be around the center of the block. To rotate around the closest point to the pointer, hold down `<Ctrl>`.

To make the model rotate in the screen plane, hold down <Alt> during rotation.

2.1.3.1.3. Model rotation

During parts and assemblies viewing, you can start continuous model rotation in the specified direction with specified velocity.

To start rotation, complete the following steps.

1. Call the **Rotate model** command .
2. Left-click the mouse in preview window, move cursor in the required direction of revolution and release the mouse button. Model will start to rotate around the center of the outline box in the specified direction.
 - 2.1. If you need to rotate the model around a point (a part's vertex, the center of a sphere, point), move the pointer to the desired element in the model window. The object will get highlighted and the pointer will take the shape appropriate to the object being selected (see Table 2.1.8). Click the left button, then hold it down and drag the pointer in the desired direction, then release the button.
 - 2.2. If you need to rotate the model around an axis, a straight edge, the axis of a conical or cylindrical face), move the cursor to the desired object in the Model window. The element will become highlighted and the cursor will take the shape that corresponds to the object being selected. Click the left mouse button. An axis or curve tangent ghost will be displayed on the screen. Click the left button, then hold it down and drag the pointer in the desired direction, then release the button.
 - 2.3. If you need to rotate the model around an axis passing through a given point of a face perpendicular to it, move the cursor to the required point in the model window and click. A ghost of an axis perpendicular to the surface running through it at the selected point. Click the left button, then hold it down and drag the pointer in the desired direction, then release the button.

Speed of the rotation will depend on how fast were the cursor movements when setting the rotation direction.

To cancel rotation, click the mouse in any part of the window. The model will stop. In this case, **Rotate Model** command is not interrupted and you can specify other direction and speed of rotation.

The **Rotate Model** command is the viewer application command. In order to use this command in KOMPAS-3D, add it to any menu or bar (see Section 9.4.2.1).

2.1.3.2. Model orientation

Position of a model in relation to the observer is called **model orientation**.

To change model orientation in KOMPAS-3D you, can use the model rotation command

Frequently, an orientation in which one of the projection planes is parallel to the screen plane is needed (in such a case, the model appearance corresponds to its image on a standard projection drawing, i.e., on the top or left view). It is hard to achieve such an orientation by rotating the model with the mouse. In this case, you can use a system-provided list of orientation names to change the orientation.

The **Orientation** button is located on the **View** toolbar. Clicking an arrow next to this button brings up a menu listing standard orientation names: **Top**, **Bottom**, **Left**, **Right**, **Front**, **Back**, **Isometric XYZ**, **Isometric YZX**, **Isometric ZXY**, or **Dimetric** (each of them corresponds to the respective viewing direction of the model).

Select a command corresponding to the desired orientation from this menu. 2.1.10). Model in window will be rotated in such a way that its position is in line with the specified sight direction.

The commands of this menu can be placed as buttons on a separate bar which then can be moved to any convenient location. To do this, drag the Orientation button by its title in any direction. The **Orientation** toolbar will be created (Fig. 2.1.11).

Note the difference of the **Orientation** bar from other toolbars: you cannot change the composition or the order of buttons on them.

Fig. 2.1.10. Orientation name selection

Fig. 2.1.11. Panel **Orientation**

Sometimes, you may need to orient an auxiliary plane or a flat face of a part parallel to the screen rather than a projection plane. In order to set such an orientation, select the required flat item and choose the line **Normal to...** from the list of orientation names or from the context menu. The model will rotate in such a way as to make the view direction perpendicular to the selected object. In this case, normal vector of flat object will be pointed at the user.

Along with using standard orientation names, you may also save current orientation under your own name (see Section 2.1.3.2.1), and then come back to it anytime, by selecting this name from the list. You can save in a user-defined orientation information about the layers at the time of creating it. In this case applying the orientation will affect not only the position of the model, but the state of the layers as well.

2.1.3.2.1. Saving current orientation

To save the current orientation of the mode, proceed as follows.

1. Click **Orientation** button on the **View** panel.

The **View orientation** will appear on the screen, see Fig. 2.1.12.

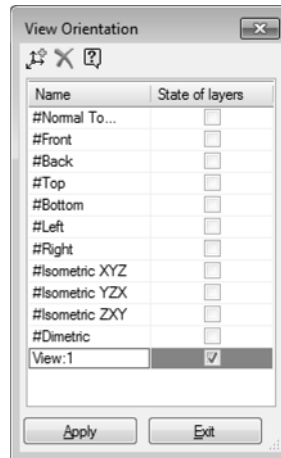

Fig. 2.1.12. View orientation selection dialog

The **Name** column contains a list of names of orientations existing in the model. The **State of layers** column shows whether the orientations store information about the layers. Layers in a model are discussed in detail in Section 2.15.13.

2. Click the **Add** button on the dialog toolbar. A new orientation will appear on the list. You can rename an orientation.

If a model, apart from the system layer, has at least one other layer, then by default the option in the **State of layers** column of the new orientation is selected. If the option is selected, along with information about the position of the model in the current orientation, layer information will be saved. To cancel saving layer status information, the option must be disabled.

3. Exit the dialogue box. To do so, click **Exit** button.

In the orientation selection dialog box, you may not only create a new orientation, but also select an existing one, as well as delete the orientation name created by user from the list.

- To select an existing orientation, focus on its name in the list and click **Apply**. The view will be re-arranged according to the sight direction specified.

- To delete an orientation from the list, highlight it and click the **Delete** button on the toolbar. The specified name will disappear from the list. You cannot delete standard orientation names (those starting with the “#” character).

User-defined orientation are also displayed on the orientation menu (Fig. 2.1.13). You may call the required command from this menu to setup a user-specific orientation.

Fig. 2.1.13. New orientation in menu

If several model windows are open in KKOMPAS-3D, each of them may have its own model orientation.

2.1.3.3. Managing orientations in the model window

You can change model orientation by rotating using the mouse **orientation control element**, found in the left bottom corner of the model window. It consists of three thick arrows — red, green and blue, indicating positive directions of the X-axis, Y-axis, and Z-axis, respectively (see Section 2.8.3.1).

Initial position of the element corresponds to the **YZX Isometry** orientation. In all isometric orientations, the central point of an element is shown as a small cube, in others—a sphere (Fig. 2.1.14).

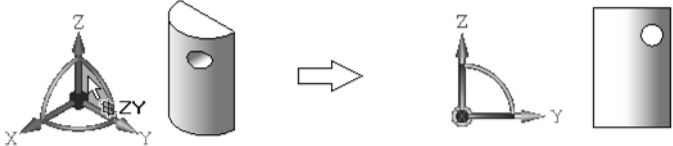

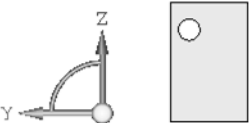

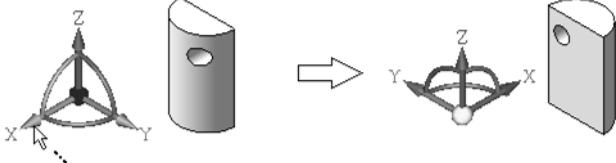

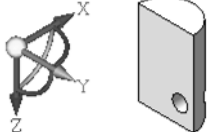

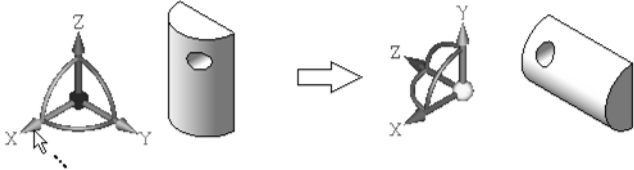

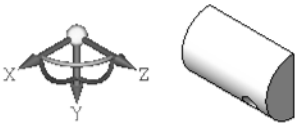

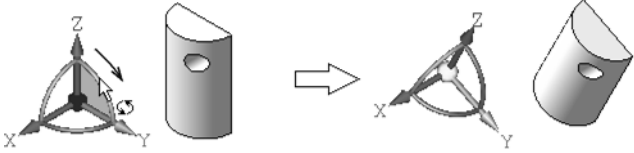

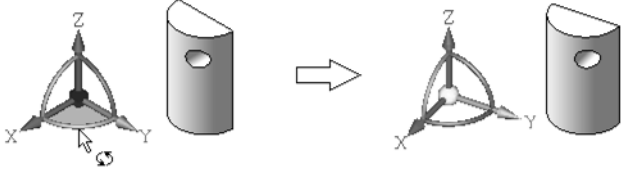

Fig. 2.1.14. Orientation control: a) in isometry, b) in any orientation

When the pointer is near the control, it activates and arcs appear on it. As you select arrows, planes or arcs on the element, they get highlighted, and the pointer changes shape. Clicking an arrow, plane, or arc (or rotating the arc by the mouse) rotates the model, clicking a sphere returns it to initial state. The techniques are detailed in Table 2.1.5.

Tab. 2.1.5. Orientation change techniques in the model window

Action	Result description
Click on arrow or perpendicular plane	Orientation front, back, top, bottom, left, right — the arrow points toward the observer . 
<Shift> + click on arrow or perpendicular plane	Orientation front, back, top, bottom, left, right — the arrow points in the opposite direction from the observer . 
<Ctrl>+ click on arrow	Rotate perpendicular plane 180° (around one of the axes of the plane): <ul style="list-style-type: none"> – if X arrow is selected—rotate plane YZ around the Z axis, – if Y—rotate plane ZX around the X axis, – if Z—rotate plane XY around the Y axis. 
<Ctrl> + <Shift> + click on arrow	Rotate the plane perpendicular to the arrow 180° (around another axis of the plane): <ul style="list-style-type: none"> – if X arrow is selected—rotate plane YZ around the Y axis, – if Y—rotate plane ZX around the Z axis, – if Z—rotate plane XY around the X axis. 

Tab. 2.1.5. Orientation change techniques in the model window

Action	Result description
<Alt> + click on arrow	Rotate the plane perpendicular to the arrow 90 ° around the axis. 
<Alt> + <Shift> + click on arrow	Rotate the plane perpendicular to the arrow 90 ° around the axis—in opposite direction. 
Arc rotation by the mouse	Rotate arc plane to an angle. 
<Ctrl>+ click on arc	Rotate arc plane with 15° step (by default). The step is set in the preferences (see Section 9.1.11.5). 
<Ctrl> + <Shift> + click on arc	Rotate the plane with a set step in the opposite direction. 
Click on sphere	Return to the YZX Isometry orientation position. 

Tab. 2.1.5. Orientation change techniques in the model window

Action	Result description
<Alt> + <Ctrl> + <Shift> + scrolling (when the pointer is near the element)	Enlarge/reduce the orientation control element.

During work with a model, e.g. when placing a component within an assembly, a similar control element will appear on the screen to change the position of the model. Working with the control is described in Section 2.11.2.5.3.

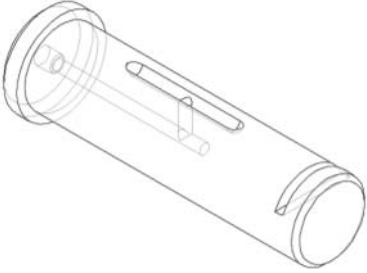

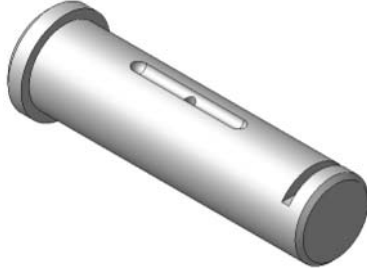

2.1.3.4. Model display

Several types model display are accessible in KOMPAS-3D. To setup the type of display, select its name in the **View – Display** menu, or press the relevant button on the **View** panel (see Table 2.1.6).

Tab. 2.1.6. Types of model display

Type	Description	Appearance
	Wireframe Range of all model edges and lines of model outline *.	
	Hidden Lines Removed Range of visible edges and visible parts of edges and lines of model outline.	

Tab. 2.1.6. Types of model display

Type	Description	Appearance
 Hidden Lines in Gray	Invisible edges, invisible parts of edges and invisible parts of outline lines are displayed in colors which differ from visible lines color * (the former are being lighter).	
 Display Shaded	Model surface display. Optical properties of surfaces (color, shine, diffusion etc.) are taken into account.	
 Halftone display With frame	Combining halftone display and display without invisible lines.	

* None of display types may influence model properties. For example, upon selection of the wireframe model display, the model remains solid filled with material (it does not turn into a set of "wire" edges), merely its surface and material are not displayed.

If several windows are opened in KOMPAS-3D, a different type of display may be enabled in each of them.

2.1.3.5. Perspective

Any optical instrument (for example, a human eye or a photo camera) captures the image of objects stretched in the instrument's axial direction with distortion, in other words, in perspective. In some cases, the perspective needs to be accounted for in order to obtain a realistic image of a three-dimensional model.

In KOMPAS-3D, the model perspective view display is supported. To get a model image that accounts for the perspective, call the **View** command. Relevant command button can be found on the **View** panel.

To switch off the perspective projection display of the model, release the **Perspective** button or repeatedly call the **Display – Perspective** command.

All types of displays listed in section 2.1.3.4 may be combined with perspective view

Fig. 2.1.15. Halftone perspective view of the model

2.1.3.5.1. Setting up options of perspective

The degree of the introduced image perspective distortion can be adjusted.

To do this, call the **Service – Parameters...**

The **Settings** dialog will appear on the screen

- If perspective view needs to be adjusted in the current window only, activate the **Current window** page and select **Prospective view settings** item,
- If perspective view needs to be setup in all newly opened windows, activate the **System** page and select **Model Editor— Prospective view setting** item.

The dialog has the single option— **Distance in Model Size**. It shows by how many times the distance from the part to the image plane is greater than the maximum part dimension. In other words, the model is shown on the screen in such a way that could be obtained by an optical instrument located at the specified distance from the model. The lesser the specified distance, the more noticeable is the image distortion.

2.1.3.6. Simplified model display mode

Parts and assemblies are displayed simplified by default.

Relatively small components and bodies of a part are replaced with rectangular blocks of appropriate size and colors in the following cases:

- Moving and rotating a model with mouse or by the commands **Shift** and **Rotate**,
- reorienting and rescaling (if the smooth transition is enabled, see Section 9.1.11.6)
- when setting small scale of display,
- moving and rotation of some components (under certain conditions).

Once the orientation or scale is changed or after zooming the display of model is restored. The mode of simplification works with all types of model displaying.

To disable simplified model displaying mode, call the command **View – Simplifications – Simplified displaying** or release button **Simplified displaying** on the **View** bar.

Settings for simplified displaying mode are changed in the dialog of system setup (see Sections 9.1.11.16.1 and 9.1.11.16.2).

2.1.3.6.1. Features of Simplifying Sub-assemblies

Displaying of sub-assemblies in the simplified mode has the following specifics.

- The rectangular box that replaces a sub-assembly is displayed in the color set for this sub-assembly when setting up its properties. Colors set for certain parts are not considered.
- If an assembly is exploded, the rectangular box that replaces the subassembly is located in the space according to the explosion parameters set for that subassembly. Explosion parameters set for certain parts in the sub-assembly are ignored.

2.1.4. General Working Techniques for Models

2.1.4.1. Selection of the objects

2.1.4.1.1. Object selection and indication

For execution of a number of 3D-element creation commands, it is necessary to **indicate** or **select** the objects on which this creation is based, such as sketches, vertices, edges and faces, auxiliary axes and planes, etc.

- Objects are **selected** when no three-dimensional construction command is active. Objects are selected in order to view them before calling a command. For example, an element needs to be selected in order to call the command of editing its parameters. In order to cancel selection of an object, you can click a vacant space of the model window and press <Esc>.
- Elements are **selected** upon defining parameters of the current command. For instance, after calling the lofted element creation command, specify the lofted sketches in succession.

To select or point an object, click it in the model window.

To execute the command, you often need to choose the object having certain geometric properties. For instance, to trim a model part by a plane, select the object that will serve as the trimming plane. Such object can be a flat face, a coordinate or an auxiliary plane.

Due to particular geometric properties, the object belongs to one of the types listed in Table 2.1.7.

Objects can be chosen in the model window (see Section 2.1.4.1.2) or in the Design Tree (see Section 2.1.4.1.5). The Design Tree makes it possible to choose the whole object and the model window makes it possible to choose separate ob-

ject parts, if any. For instance, to use the whole polyline as a path for a sweep operation, you should select it in the Design Tree, and to use one or more polyline segments, select them in the model window. One more example: by selecting an extrusion surface in the Design Tree, you can find all lines of intersection with its plane, and by selecting an individual face of this surface, you can find the line of intersection of the face with the plane.

Such object as a body can be selected in the Design Tree only. For this, the Tree must show model structure (see Section 2.1.2.2). The body can be selected not only in the Design Tree but also in the model window. Select a body face, edge or vertex for this and then call the **Select Body** command from the contextual menu.

Tab. 2.1.7. Types of model objects

Object type	Objects belonging to this type
Point objects	<ul style="list-style-type: none"> – Origin – geometric object handle in a sketch, – standalone point in a sketch, – standalone dimensional point, – 3D line vertex, – edge vertex, – group points, – points within point pattern instances, – control and connection points.
Straight Objects	<ul style="list-style-type: none"> – segment, – line in a sketch, – polyline segment, – coordinate or auxiliary axis, – straight-line edge.
Flat objects	<ul style="list-style-type: none"> – coordinate or auxiliary plane, – planar face, – sketch plane (for some commands).

2.1.4.1.2. Selecting objects in the window

When cursor moves above the model, the system automatically carries out **dynamic targeting** of items.

The dynamic targeting is a search of the object under the cursor. As soon as the object is found, it is highlighted and its symbol (see Table 2.1.8) will appear near the cursor. As the cursor moves away, the highlight goes off, the symbol disappears, and dynamic targeting resumes.

The dynamic targeting during an operation is performed taking account of the objects' types. When the cursor hovers the model, the object of the currently required type will be highlighted.

To pinpoint or select an object in the model window, move the pointer to it. When symbol of the current object appears next to the cursor and the object itself is highlighted, click the left mouse button.

Tab. 2.1.8. Cursor appearance when selecting different types of items

	Object
	Vertex
	Edge
	Face or surface
	Axis
	Plane
	Component
	Body
	3D curve or edge
	Surface
	Sketch
	Thread Notation
	The origin of the absolute or local coordinate system
	Point Control or Attachment Point
	Linear Dimension
	Linear Dimension from Line to Point
	Radial Dimension
	Diameter Dimension
	Angular Dimension

Tab. 2.1.8. Cursor appearance when selecting different types of items

	Object
	Surface finish designation
	Datum Symbol
	Leader
	Marking symbol
	Stamping symbol
	Shape and position tolerance symbol.
	Ref.No. Leader

When selecting object while holding down the <Shift> key, you select a component in the model window whose element that selected object is or to which it belongs. In this way, you can select, for example, a whole part by picking one of its elements, such as a face, an edge or a vertex. If, while holding down the <Shift> key, you select any auxiliary object, then the parts or the subassembly will be highlighted in the model window to which that auxiliary element belongs.

Sometimes, to perform a command, you need to select a group of objects.

To select multiple objects in the model window (faces, stitches, auxiliary elements, etc.), hold the <Ctrl> key down while selecting them.

To make multiple parts current in the Model window, select them while holding down the <Shift> key.

Selection of item groups and part groups may be combined This means, for example, that you may select several objects by holding down the <Ctrl> key, and then, releasing this key, press the <Shift> key (the objects will remain highlighted) and select several parts while holding it. Thus, a group of objects and a group of parts will be simultaneously selected in the model window.

2.1.4.13. Object Filters

Sometimes, when the cursor is hovered over a model, the cursor traps several objects at once (i.e. a face and its edge), and the wrong item is highlighted.

Object filters are used to help selecting objects of the desired type. To enable them, activate the **Filters** panel (see fig. 2.1.16).

By default **Filter all** button is pressed on the panel. Enabling this button indicates that all vertices, edges, faces, axes, and planes, etc.— all objects shown on the **Filters** panel— are highlighted and may be shown (selected).

If, to perform your intended action, you need to specify (select) certain objects (or object primitives), push the respective button on the **Filters** bar. Once any of those buttons is pushed, the **Filter All** button becomes released.

If all buttons corresponding to object or primitive types are switched off, then the **Filter All** button activates automatically (in other words, you cannot fully disable the selection of all types of primitives and objects).

Filtering commands are conditionally divided into three groups:

- 1st group — filtering out 3D primitives: faces, edges, vertices,
- 2nd group — filtering objects that have primitives; these include components, bodies, surfaces, sketches, curves, points,
- 3rd group — filtering objects that do not have primitives; these include constructive axes and planes, layout elements.

Buttons for calling commands of this group are separated in the **Filters** bar.

You can select several objects for filtering by pressing respective buttons on the **Filters** toolbar. You can switch the filter buttons at any time while working with the model.

Filtration by several filters at once can be done using the following methods.

- **Filter combination.** If filters are selected from 1st, 2nd or 3rd group only, in the result you will be able to filter either all primitives, or all objects whose buttons are enabled. In this case, objects are selected wholly.

- Example 1. When **Filter Components** and **Filter Surfaces** buttons are pressed, all model components and surfaces are available for selection.

If an object is selected, the cursor looks as if during the dynamic search of a component or surface.

- Example 2. When **Filter Vertices**, **Filter Edges** buttons are pressed, all model vertices and edges are available for selection.

If an object is selected, the cursor looks as if during the dynamic search of vertices or edges.

- **Overlapping of filters.** Filters are selected from the 1st and the 2nd group simultaneously, in the result you will be able to filter the primitives of the selected type of objects. Not the whole objects will be selected but only their primitives — edges, faces, or vertices.

- Example 3. When **Filter Edges** and **Filter Components** buttons are pressed, only component edges are available for selection.

If an object is selected, the cursor looks as if during the dynamic search of edges.

- Example 4. When **Filter Faces** and **Filter Points** buttons are pressed, filtering is not performing, because point do not have “face” primitive.

Filters of the 3rd group do not take part in overlapping but ensure filtering as if in a combination of filters.

2.1.4.1.4. Selecting hidden, overlapping or closely located objects

Sometimes the object to be selected in the model's window is located close to other objects or overlaps them, or is hidden beneath them. At the same time, it is difficult (or sometimes even impossible) to select it with the cursor.

To select any of the nearby-located objects (including overlapping ones), use the object picking over mode. Picking over is possible when the System is waiting for instruction or selection of an item, and the cursor traps more than one item.

In order to select one of the hidden, coincident or closely located items, do the following.

1. Point the cursor to the group of objects containing the desired object.
2. Without selecting any of them, call the context menu command **Object Picking Over**. You can also press the **<Ctrl>+<t>** keys.
3. Pick over objects by pressing the **<Space>** key or calling the **Next Object** command from the context menu. Objects pointed at by the cursor at the time of calling the picking over command will be highlighted one after another.
4. When the desired object highlights, finish the pick-over mode by confirming the selection. To do this, call the **Select highlighted object** command from the context menu or press the **<Enter>** key. You can also click the mouse on the highlighted object or at any free space of the document window.
5. To exit the picking over mode without selecting any object, call the context menu command **Cancel Picking Over**. You can also press the **<Esc>** key.

If picking over was used to select an object while performing some command, the system will return to that command.

2.1.4.1.5. Selection in the Design Tree

Some items should be selected and specified not only in the model editing window, but also in the Design Tree.

To specify or select an object in the Tree, click the mouse on its name or icon.

In this way you can select or specify a sketch, plane, axis, shape-forming or constructive element (i.e., boss-revolved element, or hole, or fillet), component or mating.

Picking and specifying objects in the Tree can be done only in the three-dimensional construction mode. If the system is in the sketch mode, then picking and specifying objects in the Design Tree is impossible (even though the Tree is displayed on the screen).

When specifying or selecting any item in the Tree, the relevant part of the model is highlighted or selected in the window.

If mate is selected in the Tree, the items are selected in the model window involved in the mating.

In order to select several items in the Design Tree, specify them by holding the <Ctrl> key.

To select multiple objects following one after another in the Design Tree, select the first (last) of them, press and hold the <Shift> key, and then select the last (first) object. The selection will be expanded to all objects in the group.

After the item has been selected using any method (including in the model window), the relevant blue icon in the Design Tree will turn green. For example, when selecting an edge, the icon of the operation that produced the edge will change color, and when selecting a plane, the icon of this plane will change color.

Once an object was selected by any available means, its respective icon in the Model Tree turns from blue to red. For example, when selecting a face, the icon of the operation that produced the face will change color, and when selecting a sketch, the icon of the sketch will change color.

Components are shown on the Design Tree as icons. There is a “+” sign next to an icon on the left side. This means that the list of items comprising the component is minimized. Therefore, the items which comprise the component may not be visible in the Tree even if they are selected in the model window.

Use **Service — Show in Tree** command to see the item in the Tree which is selected in the window model. After calling the command, the icon of the respective feature is highlighted green, while the Design Tree expands to bring the item into the view.

If the item belonging to a shape-forming element (for instance, face of extrusion element), is selected in the model window, upon calling the **Show in Tree** command the icon of relevant shape-forming element will be selected in the Design Tree, once the command Show in Tree is called.

2.1.4.2. Managing operation's parameters

2.1.4.2.1. General Information

In KOMPAS-3D, model's objects are created and edited by performing operations. Most operations have a certain set of numeric parameters. For example, numeric parameters of the extrusion operation are extrusion distance, inclination angle, and wall thickness; the numeric parameter of the scaling operation is the scaling factor.

A 3D object **handle** corresponds to each numeric parameter of operation. Handles are displayed as black squares when an operation is performed.

If a value of the operation's parameter is expressed in linear or angular values, the parameter is displayed as an (**operation's dimension** of the respective type).

In the examples above extrusion distance, inclination angle, and wall thickness are given as an appropriate dimension and a handle; scaling quotient is shown as a handle only.

Some operations are created on the basis of a sketch. If the user assigns dimensions to a sketch, these dimensions will be displayed during creation of the operation.

Dimensions of sketches and operations are displayed during creation or editing of operations only if the **Dimensions of sketches and operations** option is enabled in the dialog for setup of dimensions and designations (for more information about the setup of displaying dimensions and designations, see Section 9.1.11.12).

For more information about dimensions of sketches and operations, refer to section 2.9.2.2.

In Fig. 2.1.17, you can see an example of the extrusion element creation based on sketch. The following is displayed in the element's ghost:

- handles – as black squares,
- operation's dimensions – extrusion distance (25), inclination angle (10°), wall thickness (12),
- sketch dimensions – height (60), width (76).

Fig. 2.1.17. Example of the extrusion element creation based on sketch.

For each numeric parameter of the operation, a **variable** is created automatically. A sketch dimension variable can be created by the user (see Section 7.2.2.20). variable names are displayed beneath the dimension lines. If variable names are not displayed, call the command **View – Names of variables in dimensions**.

A number or a constant can be the value of the numeric parameter. Besides that, the parameter's value can be set by a mathematic expression.

In order to set numeric parameters of an operation, you can use the following methods:

- entry of the parameter's or expression's value for calculation of the parameter's value in the respective field of the Property bar (see Section 1.4.2.5 for more in-

formation about entry of values; information about the syntax of expressions can be found in Section 7.1.3.3.1);

- moving a handle with the mouse (see Section 2.1.4.2.2);
- setting the value of the sketch or operation's dimension (see Section 2.1.4.2.3).

If the numeric parameter of the operation is displayed as a dimension, you can assign a **tolerance** to the value of this parameter. Assigning a tolerance to the operation's parameter value is described in Section 2.10.2.2.

Numeric values of operations' parameters can be modified after creation of the operation. For more information about editing of operations' numeric parameters, see Section 2.14.3.3.

2.1.4.2.2. Objects' handles

During construction of objects, use of handles allows to change their various parameters (sizes, position, shape etc.) without keyboard, but by moving the points with mouse.

Handles of three-dimensional objects correspond to numerical parameters of the operation (numeric fields located on the Property bar). Handles are displayed as black squares.

Certain objects (for instance, spirals, extrusion features, etc.) have an abundance of numeric parameters. All handles of such objects cannot be displayed at the same time, and therefore, only the points corresponding to the numerical fields in the current Properties Toolbar tab are shown on the screen. As an example of such an object, let us consider a conical spiral. Right after calling the **Conical Spiral** command, the **Construct** tab activates on the Properties Toolbar. It has four numerical fields, and, therefore, the spiral ghost has four handles (Fig.2.1.18, a). When switching to the **Diameter** tab, these handles disappear, and the other ones corresponding to the numerical fields of the **Diameter** tab (Fig.2.1.18, b) come up.

Fig. 2.1.18. Handles of a conical spiral:

a) the **Construct** tab on Properties toolbar is active; b) the **Diameter** tab on Properties toolbar is active

To modify a parameter value, you need to activate its respective handle and move it.

To activate the point, move the mouse cursor to it. Once the point is selected and a label with the parameter name and value of the parameter appears next to it (or an expression for calculation of the parameter's value), click the left mouse button.

Drag the mouse while holding the button down. The selected handle will follow the cursor, and the respective parameter value will be changed and displayed in the text near the cursor. The object ghost will be updated dynamically. Once the desired value is reached, release the mouse button.

Some parameter values can be counted in either direction from a neutral position. When dragging a handle corresponding to such a parameter, the appropriate direction switch will be automatically activated on the Properties Toolbar. For example, an extrusion side wall draft can be directed inward or outward. When dragging an *Angle* handle from the zero position inward to the body, the **Draft Inside** switch will be activated, and when dragging it outward, the **Draft Outside** switch will be enabled.

It is more convenient to control a changing parameter value while dragging a handle in the Rounding (value approximation) mode.

To turn on this mode, press the  button on the **Current Status** Panel. When in the Rounding mode, the parameter corresponding to the handle to be moved may take only such discrete values that are multiples of the current cursor step. The value of the current cursor step is displayed in the same-name field on the **Current Status** panel. In this field, you can change— by entering from keyboard or by selecting from the drop-down menu— the cursor current step for the active window. For a shortcut to activate this field, use the **<Shift> + </>** combination (**</>** key should be pressed on auxiliary numeric keypad). The list of steps and default step can be specified in the cursor setup dialog (see Section 9.1.7.1).

2.1.4.2.3. Setting the value of operation's dimensions

One of the methods to setting the value of an operation's numeric parameter is setting the value of the dimension of operation.

In order to set the value of operation's dimension, do the following:

1. Call the dialog for setting the dimension's value. For this purpose, double-click the dimension text of the dimension in the model window.
2. Enter the dimension's value in the **Expression** field of the appearing dialog: a number, constant, or expression for calculation of the dimension's value. Syntax of expressions is described in detail in Section 7.1.3.3.1.
3. Click **Create Object** button. The dialog will be closed, and the model will be rebuilt according to the value of the parameter.

More information about the dimension value setting dialog and its usage can be found in Section 2.9.2.2.1.

The value of the sketch's dimension is set in the same way as the value of the operation's dimension.

Setting the value of the sketch's dimension is only possible if the dimension is the associative one.

2.1.4.2.4. Peculiarities of setting numeric parameters of operations in the Property Bar fields

When entering values of the operation's numeric parameters in the Property bar fields, the following peculiarities should be taken in to account.

- If a formula is input in a field, as you type it the field will display the formula, and after confirming the input (by pressing *<Enter>*)—the result of calculating it.
- The field of a parameter given as a formula has a yellow background color. To get information about the parameter, move the pointer to it. A box with the name of the parameter, name of its variable, the formula to calculate the parameter and the calculated value, will appear next to the pointer. If a new operation is created (not an existing one being edited), the text box will have no variable, since the variables corresponding to operation parameters exist in the model only after the completion of the operation.
- If a value given as a formula can be changed using a counter or a handle, a free term is added to the formula. The value of the constant term is equal to the value of the change. The sign in front of the constant term depends on whether the parameter's value increases or decreases.
- If the formula for calculating a value contains a variable non-existent in the model, after accepting the input the variable will take its default value, and the value of the operation parameter will be equal to the result of calculating the formula with the new variable. After creation of the operation, the new variable will automatically appear in the model, while its name and default value will be displayed in the main section of the Variables Window (for more details about variables, see Section 7.1).
- If only the name of the variable non-existent in the model is input in the field, the variable will take the previous value in that field. If the field contained an expression, the value of the new variable will be equal to the result of the expression's calculation. After creation of the operation, the new variable will automatically appear in the model, while its name and value will be displayed in the main section of the Variables Window.

2.2. Sketches

2.2.1. Work with a sketch

2.2.1.1. General Information on Sketches

Sketch is a 3D-modeling object, created by using tools of a drawing graphical editor. A sketch may be positioned on a coordinate or auxiliary plane, as well as on a flat face.

Sketches are used for different purposes, for example:

- ▼ setting the section form of a body or surface,
- ▼ path of the section movement construction
- ▼ Pattern instances position construction.

It is possible to use the same sketch in multiple different operations.

A special mode of working with model is used for working with sketches – **sketch mode**.

2.2.1.2. Sketch mode

Sketch mode is a special KOMPAS-3D three-dimensional model operation mode. You can switch to this mode when creating a new or editing an existing sketch.

Working in the sketch mode is practically the same as working with a KOMPAS fragment. The difference is that it is impossible to create such objects as technological designations and tables, hatches, fillings, break lines and some others. This is due to the fact that, unlike graphic objects, they are not involved in creating the three-dimensional feature geometry when sweeping the sketch and, unlike dimensions, they do not define the sketch configuration.

By default, the **parametric mode** is enabled in a new sketch. For detailed aspects of working in this mode, see Section 7.2.1.7; for detailed information about parametric mode setup in a sketch see Section 9.2.7.7.1 on p. 1864.

Commands for 3D modeling are not available in the sketch mode. Model objects can be used in a sketch for projecting or snapping (see Section 2.2.2.3 on p. 146).

When you finished working with a sketch, exit the sketch mode to continue creation of a model. See Section 2.2.1.4 for more information about using sketches in operations.

2.2.1.3. Sketch status diagnostics

If the sketch is a parametric one, it can be in one of the three states: **fully defined**, **not fully defined** or **redefined**. These statuses are indicated by symbols in front of sketches' names in the Design Tree:

- (+) — fully defined sketch, i.e. its objects having no freedom degree in the sketch coordinate system,
- (-) — not fully defined sketch.
- (!) — redefined sketch.

It is recommended, that all sketches in a model were fully defined. In this case, the equation systems of sketches are solved in a more stable fashion.

To view or edit sketch state, enter into its edit mode. Enable display of object constraints (see Section 7.2.5.1 on p. 1620) and degrees of freedom (see Section 7.2.5.2 on p. 1624), if it is disabled.

- ▼ If a sketch is fully defined, none of its objects has degree of freedom, i.e. if degrees of freedom are enabled, their symbols are not displayed.
- ▼ If a sketch is not fully defined, then at least one of its objects has at least one degree of freedom. In order to fully define a sketch, relation and/or limitation objects should be applied to it in such a way, so that none of the objects have any degree of freedom.
- ▼ A sketch is considered to be redefined, if surplus relations and/or limitations are applied to its objects (while objects' degrees of freedom may be present or absent). Surplus relation and/or limitation symbols are displayed in brown color. For example, a surplus relation is the *Parallelism* applied to segments that already have the *horizontality* limitation.

If a sketch is non-parametric (i.e. its objects are neither not related to each other nor to model objects and have no limitations), no symbols are used in front of its name in the Design Tree.

2.2.1.4. Using a sketch in operations

Outside the sketch mode, only some of graphical objects built in it are displayed – those that lie in the current layer and in active layers (there are may be several layers in a sketch, as well as in a fragment, see Section 3.5.6 on p. 1181) and are of one of the following types and/or styles:

- ▼ point,
- ▼ Centerline,
- ▼ Line with the *Basic* style,
- ▼ Line segment with *Axis* style.

When performing operations that use a sketch, only those its graphical objects are taken into account that are visible outside the sketch mode.

Dimensions that are set in the sketch are available when performing an operation and when enabling special mode (see Section 2.9.2.2 on p. 632).

Thus, if auxiliary objects are required for creating an image in a sketch (especially, parametric) that should not be taken into account when performing an operation, use the line style for them that is other than *Basic* or *Centerline*.

Move the dimensions, that should not be visible outside the sketch mode, to a hidden layer.

A sketch specified for using in an operation is interpreted by the system as one or several **contours** made of the sketch's lines.

Note that sketch's lines are always fully included in the sketch. For example, if two segments are created in sketch, and they connect with each other at the vertex, they make up the same contour, while if segments intersect with each other, there are will be two contours. Also, two contours are made by three segments with a common vertex.

If sketch's lines form several contours, correct performance of the operation usually requires that the contours have no common points, do not intersect or be tangent to each other. There are more requirements to sketches. These requirements depend on operations that use sketches and are described in sections dedicated to operations.

In some operations, you can use both the whole sketch (i.e. all of its contours), and in this case the sketch has to be specified in the Design Tree, or only some lines of the sketch, in which case they have to be specified in the Model Tree.

2.2.1.5. Selecting a plane for sketch construction

Operation sketch plane selection does not affect further steps of working with the model and its properties.

However, when selecting a plane for a sketch of the first body or surface, it should be borne in mind that object's position in the standard orientation will depend on this selection. For example, if section sketch of an extrusion body is constructed in the XY plane, then the body projection on the front view will coincide with the shape of the sketch (Fig. 2.2.1).

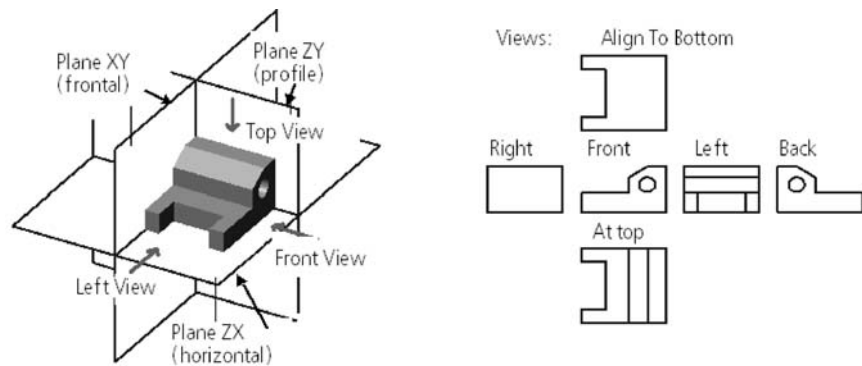

Fig. 2.2.1. Position of part relative to coordinate planes

2.2.1.6. Sketch from Library

Instead of creating a new image in the sketch from scratch, you may insert objects already available in the sketch library into it (for details, see Section 12.1.4.2 on p. 2044).

2.2.1.7. Orientation of sketch's plane and sketch's view scale

It is convenient to construct a sketch if its plane coincides with the plane of screen. If the sketch plane is perpendicular to the screen plane, construction is impossible.

By default, the system is set in such a way that when entering the sketch mode the model is automatically turned into **Normal to...** orientation relative to the sketch plane, and, upon exiting the sketch editing mode, it shall return into initial position.

The sketch's view scale is specified in the following way:

- ▼ when a new sketch is created, it is equal to 1 (if the sketch is created in the coordinate plane) or selected in accordance with the object's dimensions (if the sketch is created on an auxiliary plane or flat face),
- ▼ if an existing sketch is edited, it is selected by the image's dimensions in the sketch, i.e. the **Show the sketch in full** command is performed automatically.

Automatic setting of orientation and scale can be modified in the display settings dialog (see Section 9.1.11.5 on p. 1728).

If the model automatic reorientation is disabled, then the sketch plane can be manually reoriented parallel to the screen.

To do this, command **Normal to...** is used.

You can set the sketch plane into **Normal to...** orientation both before and after switching over into sketch mode. In the first case, you should select the plane of the future sketch and call the **Normal to...** command from the context menu. In the second case, selection of the plane is not obligatory—you may simply apply the **Normal to...** command from the context menu (it is accessible, if none of the geometric construction commands is active) or from the **Orientation** button menu.

2.2.2. Sketch creation

2.2.2.1. Sketch creation process

The sketch is positioned on a flat object — coordinate or auxiliary plane or flat surface. This object can be specified both before entering the sketch mode and afterwards.

1. Call the **Operations – Sketch** command or click the **Sketch** button on the **Current state** bar. The **Sketch** button will remain enabled. It means that the system is in the sketch edit mode.
 - ▼ If a flat object is selected prior to calling the command, the sketch will be created within this plane and the sketch's coordinate system will have the default position.
 - ▼ If no flat object have been selected, the process of sketch positioning will be run automatically (see Section 2.2.2.2 on p. 145). Specify the required flat object.

The operation's icon appears in the Design Tree. It is marked with the “lock” icon denoting that the sketch is currently being edited.

The compact bar and Main Menu will be modified. Commands for creation and editing of graphic objects, selection, measurements, dimension settings, parametric relations and limitations will become available.

The sketch's coordinate system will be displayed on the screen.

2. Create the required image in the sketch.

You can import a draft into a sketch from a previously created drawing or fragment via the clipboard. This helps to rely on existing drafting design documentation when creating a three-dimensional model.

- To return to the mouse of 3D construction, call the **Operations — Sketch** command again or release the **Sketch** button in the **Current status** bar or click on the sketch mode icon in the document window.

Right after leaving the sketch mode, the new sketch is selected in the graphic area.

Commands for running operations that can be performed based on the created sketch can be called directly in the sketch mode. For example, having created an extrusion body section in the sketch, you can immediately call the **Extrusion operation** command. The sketch edit mode will be finished automatically, and the extrusion body creation command will be run.

A sketch is an object that uses coordinate system (for object coordinate system, refer to Section 2.8.3.4.1 on p. 598).

2.2.2.2. Sketch Positioning

Sketch positioning is the selection of a plane for it and setting the position of its coordinate system on this plane.

The sketch positioning process starts after calling the **Sketch** command if no plane or flat face had been specified before running it.

By default, automatic object creation is enabled during the sketch positioning process (see Section 1.4.2.10 on p. 93). Therefore, once the plane or flat face for sketch positioning is specified, the system will immediately enter the sketch construction mode. If you need to perform other operations in addition to specifying a flat object, such as setting the position of the sketch's coordinate system or disabling the sketch's link to the plane in which it is positioned, switch off automatic creation by disabling the respective button in the Advanced Control Panel.

In the process of sketch positioning, a ghost of the sketch's coordinate system is displayed in the graphic area while the Property bar looks as is shown in Fig. 2.2.2.

Fig. 2.2.2. Property bar in the process of sketch positioning

In order to define a plane for sketch positioning, specify an auxiliary or coordinate plane or a flat face. The selected object will be highlighted in the model window, while its name will appear in the **Base plane** field in the Properties ar.

In order to move or turn the sketch's coordinate system with respect to its initial position, enter values for coordinates and angle in the **Snap point** and **Angle** fields in the Property bar. Change of coordinates and angle will be reflected in the sketch's coordinate system ghost, in the graphic area.

The coordinate system of the sketch may also be moved as needed or turned by the mouse. For this purpose, cancel fixation of the **Snap point** or **Angle** field in the Property bar and then specify the new position or rotation angle of the sketch's coordinate system in the graphic area.

If you do not need the sketch to be related to the base plane, enable the **Independent Location** option. The sketch will keep its position in space, but its link with the base plane will be broken (the base plane will no longer be highlighted in the Model Window, and its name will be deleted from the **Base Plane** field).

Click **Create Object** on the Advanced Control Panel in order to confirm the position of the sketch.

2.2.2.3. Using model objects when creating a sketch

When working with sketch, you have the following options.

- ▼ **Snap to model objects** when creating geometric objects and dimensions. In this case, auxiliary projection of the model's object is formed in the sketch. The created object is parametrically linked to the projection. Snapping to model objects is described in Section 2.2.2.3.1 on p. 146 and construction projection — in Section 2.2.2.3.2 on p. 147.
- ▼ **Use model objects as base items** when creating geometric objects and dimensions. To do this, just indicate model objects when creating/editing the image in the sketch. As a result, a construction projection of the model object is generated and the sketch object is linked to it. Examples: a segment parallel to the edge parallel; the angular dimension between the projection of a straight object¹ and the segment, the *equality of lengths* link between the segment and the projection of a straight object. Construction projection is covered in Section 2.2.2.3.2 on p. 147.
- ▼ **Project model's objects** on the sketch's plane. A geometrical object will be formed in the sketch that will be linked to the model's object directly. Projection of objects is detailed in Section 2.2.2.3.3 on p. 148.

Availability of 3D object choice when working with the sketch depends on filter settings (see Section 2.1.4.1.3 on p. 133). By changing the settings, you can narrow down or expand the range of objects available for specification.

2.2.2.3.1. Snapping to model object when working in a sketch

When creating geometric objects in a sketch, you can use global and local snapping not only to geometric objects of the sketch, but also to model objects. Detailed description of global and local snapping can be found in Section 3.1.1.2 on p. 865. This section describes peculiarities of snapping to model objects.

For the snapping, you can use model objects representing points (vertices, zero points, and so on) or curves (edges, 3D curves, axes, and so on). As a result of snapping, an auxiliary projection of the object, selected for snapping, is formed in the sketch (see Section 2.2.2.3.2 on p. 147), while the created geometric object is parametrically linked to the ghost.

The snap is done as usual: in the process of its creation, position the cursor on the required model object and click the mouse when auxiliary projection of the selected object, snap name and snap point designation (X) appear in the sketch's plane.

For example, if you need to create a segment with the beginning in the middle of the edge's projection, call the **Segment** command, enable global and local snap **Middle** and move the

1. Axes of coordinate systems available in the model can also be used.

cursor to the required edge. Click the mouse as soon as projection of the edge appears in the sketch's plane and X with the *Curve's middle* text appears in the edge's middle.

Keep in mind the following when snapping to model objects.

- ▼ In case of a straight-line object located perpendicular to the sketch's plane, you can only snap to the vertices of the object.
- ▼ It is impossible to create two or more auxiliary projections at the same time. Therefore, it is impossible to make the **Intersection** snap without projecting objects to the sketch whose intersection point is used for snapping.

If necessary, you can disable snapping to all model objects or only to those that are not visible in its current position. For this purpose, the following commands are used: **Snapping to model elements** and **Only to visible model elements** in the **Snaps** button menu (Fig. 2.2.3).

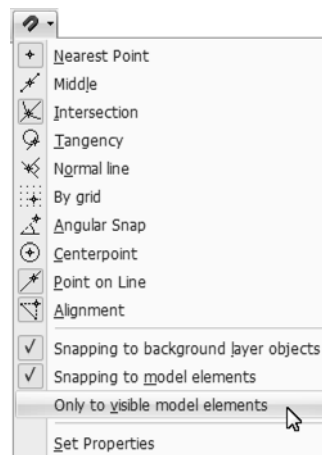

Fig. 2.2.3. Commands for controlling the snap to model objects

2.2.2.3.2. Auxiliary projection of model's object

Construction projection of a model object is created in the sketch automatically when being snapped to the model object and when the model object is used as basic for the sketch object.

Auxiliary project is present in the sketch as long as it takes part in any parametric relations. If the final relation applied to an auxiliary projection is deleted, the projection will be deleted automatically after the work with the sketch is finished.

For example, when specifying the position of the first segment's vertex, snap was made to the center of a round edge. As a result, edge's auxiliary projection (circle or ellipse) has been created in the sketch. The *merged points* relation is formed between its center and vertex. Subsequently, the first vertex of the segment had to be moved to another point and the relation was deleted for this reason. If there are no other relations applied to the construction projection, the projection will be deleted when the sketch mode is exited.

If the parametric mode is disabled in the sketch, or parametrization of snaps is disabled during its setup (see Section 9.2.7.7.1 on p. 1864), no relations are applied during the snap and no auxiliary projections are created.

The user is able to control the auxiliary projection displaying in the sketch. The **Auxiliary projections** button in the **Current state** bar is used for this purpose. If the button is enabled, all auxiliary projections that are present in the sketch will be displayed with dashed lines.

A sketch can contain construction projections right after it is created. This depends on what is used as the sketch plane. Example:

- ▼ a sketch in a flat face contains construction projections of edges of this face,
- ▼ a sketch in a coordinate plane contains construction projection of the origins,
- ▼ a sketch in a plane built by three points contains construction projection of these points,
- ▼ a sketch in a plane built through an edge parallel to another edge contains construction projections of these edges,
- ▼ a sketch in an offset plane does not contain construction projections.

Construction projections that originally existed in the sketch are not deleted from it even if they are not involved in any parametric relations.

2.2.2.3.3. Projecting model's objects to sketch

Sometimes, lines or points need to be created in the sketch to represent 3D object projections to the sketch's plane.

To create a projection of an object, apply the **Operations — Project Object** command. Button to apply this command is located on **Geometry** panel.

Specify the object the projection of which should be obtained — a vertex, face, edge, 3D curve, axis, point and so on.

Projection of the specified object is created in the sketch.

Depending on which object is selected for projecting, only one of the following geometric objects can be created in the sketch:

- ▼ point with the *Auxiliary* style, if a vertex is projected,
- ▼ auxiliary line, if coordinate or auxiliary axis is projected,
- ▼ object of the **projection curve** type of the *Basic* style, if an edge, 3D curve or face is projected; in the latter case, projection curves are created (edge projections) that limit the face.

If a straight-line edge perpendicular to the sketch's plane is selected for projecting, one of the edge's vertices will be projected to the sketch.

A parametric relation (the *projection relation*) is automatically applied to the created projection. This ensures permanent link of the projection to the source 3D object.

Removal of the *projection link* relation results in removal of the link between the projection and source object. Projection becomes an ordinary geometrical object which can be moved or edited. The result will be the same if the **Explode** command is applied to the projection.

Projection of end vertex relations are also applied to the projection curve, if it is open. These relations ensure coincidence of outermost vertices of the projection curve with projections of outermost vertices of the source object.

Several different object projections can be built in a sketch in a single call of the **Project object** command. For this purpose, they should be specified one by one.

To finish projecting, click the **Interrupt command** button in the Special Control Panel.

Working with the projection curve

- ▼ It is impossible to change the projection curve's form (for example, it is impossible to change a circle's arc radius). However, the curve can be trimmed. Projection curve can also be used as a restricting object in the alignment or extension commands.
- ▼ If a projection curve is cut in several sections, all other sections will be selected, if one of them is selected.
- ▼ The length of the projection curve can be modified by moving handles on its ends (or ends of its parts). To move an end point of the curve, delete the *projection of end vertex* link laid on it. A point can only be moved along the curve. If the projection curve is a segment or arc of a circle/ellipse, handles can be moved along the curve's extension (i.e. the curve can be made longer than the projection of the original object).
- ▼ When copying a projection curve, a normal geometrical object (or objects) is created.
- ▼ Editing commands can be applied to the projection curve, if the mode, in which source objects remain after the command execution, is enabled in them. As a result of these commands, an ordinary geometrical object (or objects) is created.
- ▼ In order to restore the initial state of the projection (after section, for example), use the **Restore curve** command in the context menu. The command is available in the context menu as long as the curve maintains a link to the source object (i.e. there is a *projection link* in the list of constraints imposed on it).

2.2.2.4. Peculiarities of using some type of objects in a sketch

2.2.2.4.1. Polygon, rectangle, polyline

Polygons, rectangles, polylines created in a sketch are automatically split to separate segments (they do not remain single objects as in the event of working with graphic documents). In the parametric mode, relations and limitations are applied to these segments. For example, *horizontality* and *verticality* limitations are applied to a rectangle's sides. *Coincidence* relations are applied to their vertices.

Polygons, rectangles, polylines copied to a sketch from graphic documents are not split to segments.

2.2.2.4.2. Text

Sketch may contain text. After leaving the sketch mode, all text contained it will be automatically transformed into one or several contours that consist of spline curves.

Sometimes, automatic transformation may result in contours that do not meet the requirements of an operation (tangent, for example). In such cases, you can try to change the text's font. If a contour still does not fit an operation, you can apply the **Transform into NURBS** command in the sketch. The resulting lines will not be text (i.e. text must be entered and trans-

formed into NURBS again in order to edit it). However, they will follow the letters' contours, and you will be able to correct the sketch so that it meets the operation's requirements.

Text after NURBS transformation will have to be deleted from the sketch or moved to its hidden layer.

2.2.2.4.3. Insertion of fragments, macro elements

The following sketch objects **cannot be used** to perform operations:

- ▼ macro elements inserted from libraries or copied through the clipboard from graphic documents,
- ▼ fragments inserted from libraries,
- ▼ insertions of local or external fragments made using the **By external link** or **Embed in document** method.

Fragments and macro elements must be split into separate geometric objects after insertion to the sketch using the **Editor — Explode** command.

2.2.2.4.4. Technological designations, tables, hatches

It is impossible to create technological designations, tables, hatches and some other objects in sketches.

If some of the objects, that cannot be created in a sketch, appear in the sketch (for example, copied from a graphic document), you can keep working without problems. These objects will just be disregarded when creating a three-dimensional feature. They are saved in the sketch. They can be reviewed while editing the sketch.

2.3. Bodies

2.3.1. General Information on Bodies

You can create a new body in a model using one of the following operations:

- ▼ **Extrusion.** Creates a body by sweeping a section along a linear path a given distance (see Section 2.3.2 on p. 152).
- ▼ **Rotation.** Creates a body by rotating a section around an axis with a specified angle (see Section 2.3.3 on p. 166).
- ▼ **By Sections.** Creates a body by connecting several sections (see Section 2.3.5 on p. 177).
- ▼ **Sweep Feature.** Creates a body by sweeping a section along any given path (see Section 2.3.4 on p. 173).
- ▼ **Thickening.** Creates a body by adding a material layer to a specified surface (see Section 2.3.6 on p. 184).
- ▼ **Sheet Body.** Creates a special body type — a sheet body (see Section 2.4 on p. 231).
- ▼ **Surfaces Knitting.** Creates a body surrounded by the specified surfaces (see Section 2.6.2.4 on p. 478).

Once the new body has been created, additional volumes are “attached” to it or “cut” out of it, i.e. the body's material is being added or removed (Fig.2.3.1).

Fig. 2.3.1. Constructing a body:
a) new body— cylinder; b) prism adding;
c) “cut” of a prism; d) “cut” of a cylinder

Examples of removing material of a part are various holes, slots, or grooves, while examples of adding volumes are bosses, protrusions, and edges (Fig. 2.3.2).

Fig. 2.3.2. The boss and the feet are glued to the body whereas the slots and holes are cut from it.

Adding and deleting extrusion, revolution, lofted, swept features are described in Sections 2.3.2–2.3.4; adding a material layer to the body faces is described in Section 2.3.6 on p. 184. Other options for body editing (adding chamfers, fillets, edges, creating shell, etc.) are described in Section 2.3.8 on p. 187.

A model may consist of multiple bodies. Boolean operations can be performed with bodies (see Section 2.3.7 on p. 185).

Using bodies that are present in the model, you can create new ones using array building commands, see Section 2.7 on p. 509.

2.3.1.1. How to start creating a model

Before creating a model, user always faces the question how to start creating. To answer this question, you need to have an approximate idea of the future part design.

Conceptualize the structure from chamfers, fillets, grooves and other small structural features. Divide the part into constituent features (parallelepipeds, prisms, cylinders, cones, tori, swept features etc.).

Most often, the largest of those features is created first. If the structure of the part has several features of comparable sizes, you can start construction with any of them.

Sometimes, it may be rational to construct several bodies and then combine them to create such a part. Some parts, for example, segmented washers, are made of several bodies not connected to each other. Multibody modelling is detailed in section 2.3.12 on p. 228.

Sometimes, a simple feature circumscribing the part to be designed (or its portion) is used as the base (i.e., a block or cylinder).

In some cases, the selection of the first element (and the order of further part design) may be done based on the manufacturing technology involved.

Generally speaking, there are no universal instructions for creating three-dimensional models. Designers gain experience in a preferred modelling approach after independently creating several models.

2.3.2. “Extrude” and “Cut by extrusion” operations

2.3.2.1. Extrusion Feature

Extrusion feature is created by sweeping section along the straight-line guide in either or both sides at the specified distance. For example, a feature shown in Fig. 2.3.3, is created by extruding a sketch in the direction perpendicular to its plane.

Extruded element may be an individual body or may be attached to a body or cut out of it.

Operation **Extrude** serves to create a new body of extrusion or to add an extrusion feature to an existing body (i.e. to add a material), operation **Cut-Extrude**— to cut an extrusion feature from a body (to remove material).

Fig. 2.3.3. Sketch and element produced by the extrusion operation

A face, sketch, edge or 3D curve (including contour constructed by sketch lines, by face edges or arbitrary¹) may be used as a section of extrusion feature.

During extrusion of face, closed sketch, closed **Contour on Face** or **Sketch Contour**, the choice between thin wall and body feature is available. (Fig.2.3.4). If section is open, only thin wall feature construction is available.

Fig. 2.3.4. Face extrusion: a) section (cylindrical face), b) body feature, c) thin wall feature

If section is a flat face, sketch, contour constructed by sketch lines or flat face, and it is extruded at the direction perpendicular to it, sloping to side faces of feature is possible (Fig.2.3.5).

Fig. 2.3.5. Slope of side faces of extrusion feature:
a)

During edge or 3D curve extrusion (including contour of **Arbitrary** type), only thin wall feature construction is possible. Slope of side faces is impossible. Example of 3D curve extrusion is shown in the Figure2.3.6.

Fig. 2.3.6. Extrusion element with a spiral section

1. It means that has **Contour on Face**, **Sketch Contour** and **Arbitrary Contour** type, see Section 2.5.4.24.1 on p. 438.

2.3.2.2. Execution of the operation

1. Start an operation. To do this, complete the following steps:

▼ click the required button on the **Edit Part** or **Edit Model** panel.

▼ or call the required command from **Operations** menu.

Availability condition of **Cut-Extrude** command: model including a body or a component.

After operation launch, tabs with operation parameters controls appear on the Properties bar.

2. Specify the operation parameters:

▼ **Section** (see Section 2.3.2.3).

▼ **Extrusion Direction** (see Section 2.3.2.4).

▼ **Extrusion Depth** (see Section 2.3.2.5).

▼ **Inclination Angle** (see Section 2.3.2.6).

▼ **Thin Wall Settings** (see Section 2.3.2.7),

▼ **Result** (see Section 2.3.2.8).

All parameter values, once entered or modified, are immediately displayed on the screen as the ghost of the extruded feature. A ghost allows a visual control over parameter accuracy.

To set up such parameters as slope angle and wall thickness, extrusion direction and depth, you can use handles (handles are detailed in Section 2.1.4.2.2 on p. 138).

3. Click **Create Object** button to complete the operation.

4. If such operation results in a body comprising several parts, the Modify set of parts process will be started automatically after the end of the operation. Select the parts to be hold (see Section 2.3.11.1).

Operation result — new body, pasted or cut element — appears in the graphic area.

The operation's icon appears in the Construction Tree. It coincides with icon on the button of command which starts operation. Exception is an icon of new extrusion body— it differs from an icon on the button.

an icon of new extrusion body

2.3.2.3. Extrusion feature section

2.3.2.3.1. Dependence of the result of extrusion operation of the section

In Table 2.3.1, you can see peculiarities of the extrusion operation's performance and results depending on the choice of section.

Tab. 2.3.1. Peculiarities of extrusion operation execution, depending on an object used as a section

Object	Peculiarities of operation execution and result
sketch, contour created by sketch lines	<ul style="list-style-type: none"> ▼ if section is closed, you can create both thin wall and body feature ▼ slope of feature side faces is possible ▼ sketch must meet the requirements presented in Section 2.3.2.3.3
face, contour created by face edges	<ul style="list-style-type: none"> ▼ you can create both thin wall and body feature (if a closed contour section is used) ▼ if a face is planar, slope of feature side faces is possible
edge, 3D curve, arbitrary contour	<ul style="list-style-type: none"> ▼ only thin wall feature can be created ▼ slope of feature side faces is impossible

2.3.2.3.2. Specification of extrusion feature section

You can use an existing object in the model as a section of the extrusion element— an edge, curve, sketch or face, or you can create a new object— contour— without interrupting the operation.

To select the existing object as a section, specify it in the Design Tree or in the graphic area.

To create a contour, click the **Contour** button on the Advanced control panel. Contour creation process will be started (see Section 2.5.4.24 on p. 437). Specify objects included into contour and click **Create Object** button. The system will resume the extrusion operation process, created contour will appear in the Design Tree and will be automatically selected as a extrusion feature section.

Name of the section object shall appear in the **Section** field on Properties toolbar.

If, when moving section in the preset direction, two or more section points have the same paths, it will not be possible to complete the operation. You need to change section or direction.

Extrusion feature section can be specified before the operation launch.

You can change extrusion feature section at any time. To do this, activate **Section** switch and then specify the desired object or construct a contour.

A sketch selected as an extrusion feature section can be edited without interrupting the operation. To do this, click the **Edit Sketch** button on the Special Control Panel. The system will switch to the sketch editing mode. Make the necessary modification in the sketch. Then click **Sketch** button on the **Current status** panel or click the sketch mode icon in the document window to return to the extrusion operation process.

2.3.2.3.3. Extrusion Feature Sketch Requirements

- ▼ Sketch objects can be a part of one or several contours.
- ▼ If there are several contours, they all should be either closed or open.
- ▼ If the contours are closed, they can be nested. The level of nesting is not limited.

2.3.2.4. Direction of Extrusion

2.3.2.4.1. Guide Object

If the feature section is a sketch or flat face, this object is automatically selected as a guide. If section is contour created by sketch or by flat face edges, a corresponding sketch or face is automatically selected as a guide object. If necessary, you can change guide object.

You can use the following guide objects for extrusion:

- ▼ An existing planar or straight-line object (the list of objects is provided in Table 2.1.7 on p. 131).
 - ▼ Straight-line object defines direction parallel to itself.
 - ▼ Planar object defines direction perpendicular to its plane.
- ▼ Vector.

To select an existing object as a guide, activate **Guide Object** switch on the Properties bar and then specify the required object in the Design Tree or in the graphic area.

To create a vector, click the **Vector Drawing** button on the Advanced control panel. For more details about drawing vectors, see Section 2.8.5 on p. 613.

The name of the guide object is displayed in the **Guide Object**.

2.3.2.4.2. Selecting the extrusion direction

The corresponding direction of extrusion can be selected from the **Direction** list (see Table 2.3.2) in the Property bar.

Tab. 2.3.2. Available directions of extrusion

	Value of Direction option	Direction of extrusion. Specifics of defining extrusion depth
	Forward	In the forward direction relative to the section* . When choosing this option on the property bar, there is the Method 1 list to select a method of setting the extrusion depth (see Section2.3.2.5).
	Reverse	In the reverse direction relative to the section* . When choosing this option on the property bar, there is the Method 2 list to select a method of setting the extrusion depth (see Section2.3.2.5).

Tab. 2.3.2. Available directions of extrusion

	Value of Direction option	Direction of extrusion. Specifics of defining extrusion depth option
	Two directions	In both directions relative to the section. When choosing this option on the property bar, there are Method 1 and Method 2 lists to select a method of setting the extrusion depth in each direction (see Section 2.3.2.5).
	Middle plane	To both directions symmetrically relative to the section. If this option is selected, Method 1 and Method 2 lists are unavailable, for only one method to define the distance, i.e., the exact setting of overall extrusion depth, is available. Enter the required value into the Distance 1 .

* To make out directions (forward and reverse), the ghost in the detail viewing window has an arrow indicating the forward direction. If **Forward Direction** option is selected, extrusion shall be done in the direction of the arrow. If **Reverse Direction** option is selected, the revolution shall be done against the arrow.

2.3.2.5. Depth of Extrusion

Once the direction is selected, you need to specify the distance extrusion value. To do this, select the desired option from **Method 1** (and/or **Method 2** — depending on the selected direction) list on the Properties bar. The list of methods of selecting the extrusion depth has the following options (see below):

▼ **At Distance,**

▼ **Through All,**

▼ **Up to Vertex,**

▼ **Up to Surface,**

▼ **Up to Nearest Surface.**

2.3.2.5.1. Extrusion at the specified distance

Extrusion is done exactly for the distance specified in **Distance** field.

Fig. 2.3.7. Extruding by a distance

2.3.2.5.2. Extrusion through all

Depth of extrusion is defined automatically.

The element is extruded before it reaches the plane that goes perpendicular to the extrusion direction through the dimensional 3D cube's outermost point from the section in the extrusion direction.

Fig. 2.3.8. Extrusion through all

When creating a circumscribing block, only bodies are taken into account, therefore, if there is no bodies in model, **Through All** method of depth definition is unavailable.

2.3.2.5.3. Extrusion up to vertex

Depth of extrusion is defined automatically by position of a vertex selected by user.

Fig. 2.3.9. Extrusion up to vertex

- ▼ If a face, sketch, or contour built by sketch lines or face's edges, are used as a section, the depth is calculated so that the element's endface (or its continuation) goes through the specified vertex.
- ▼ If an edge, 3D curve, or arbitrary contour are used as a section, the extrusion depth is calculated as the distance between the specified vertex and the point nearest to the section which lies on the straight line going through the vertex in the extrusion direction.

To specify a vertex defining extrusion depth, activate **Vertex** switch on the Properties bar and select the desired point object in a graphic area (point can be also specified in the Design Tree). The name of the selected object is displayed in a field beside the switch.

Using the **Cut** option, you can cut the element with a plane going through the specified vertex perpendicular to the extrusion direction. In this case, the element will have a flat endface irrespective of the section form.

If necessary, you can set the distance at which the element's endface should be positioned from the vertex, i.e. increase or decrease the automatically defined extrusion depth (see Section 2.3.2.5.6 on p. 160).

Extension of complex shape faces is not always possible. Therefore, if the specified vertex is positioned in such a way that, provided the extrusion direction is set, the element's endface does not go through the vertex, in some cases, construction will only be possible if the **Cut** option is enabled.

2.3.2.5.4. Extrusion up to surface

Depth of extrusion is defined automatically by position of a face or a plane specified by User.

Fig. 2.3.10. Extrusion up to surface

To specify a surface defining extrusion depth, activate the **Face** switch on the Properties bar and select the desired object in a graphic area. The name of the selected object is displayed in a field beside the switch.

The element is extruded up to the selected surface. The endface of the feature has the surface form.

If necessary, you can set the distance to the element's endface from the surface (see Section 2.3.2.5.6 on p. 160).

It is recommended to choose section, direction, and surface so that the surface fully intersects the extrusion element. Otherwise, the construction is done only in case of selected surface can be extended. Extension of complex shape surfaces is not always possible.

2.3.2.5.5. Extrusion up to nearest surface

Depth of extrusion is defined automatically. The feature is extruded precisely to the nearest faces of the part in the extrusion direction (in other words, until the extrusion will meet a face (or faces) on its way). The endface of the feature has the face (faces) form.

If there are no bodies in a model, **Up to Nearest Surface** method of depth definition is impossible.

It is recommended to choose section and direction so that the extrusion element intersects bodies existing in the model.

Fig. 2.3.11. Extrusion up to nearest surface

Method of defining the **Up to Nearest Surface** depth is useful for extrusion of an feature up to a stepwise or curvilinear edge (see Fig.2.3.12).

Fig. 2.3.12. Extrusion of a feature up to the nearest curvilinear surface

2.3.2.5.6. Setting distance to the object

If **To Vertex** or **To Surface** method of creating was selected, then, after vertex or surface specifying, you need to specify distance to it.

To do that, enter required distance between end face of the feature and the object into the **Distance** field.

If the object is to be extruded exactly up to the object, enter zero distance.

If the distance to the object is nonzero, it can be applied either in the extrusion direction (in this case, the feature will be extruded “overshooting” the object by the specified distance), or counter to the extrusion direction (in this case, the feature “undershoots” the object by the specified distance). To specify direction of measuring the distance to the object, activate **Before Object** or **Behind Object** switch in the **Type1** group.

Fig. 2.3.13. Extrusion of feature:
a) exactly to the vertex; b) behind the vertex; c) close to the vertex

In case of extrusion to the surface, the equidistant surface is created at a preset distance from it, up to which the extrusion is made.

2.3.2.6. Angle of Slope

Slope of side faces of extrusion feature is possible if the following conditions are satisfied:

- ▼ If a flat face, sketch, contour constructed by sketch lines or flat face edges is used as a feature section,
- ▼ extrusion direction is perpendicular to section plane.

To extrude in the forward or reverse direction (Fig. 2.3.14), specify the direction of the slope by activating the **Inward** or **Outward** switch in the **Slope** group. Enter the inclination angle value in the **Angle** field.

To extrude in both directions, the direction and the slope value are required to be input twice, for both forward and reverse directions (Fig.2.3.15).

To extrude from midplane, the slope parameters are specified once and considered equal in both directions.

Fig. 2.3.14. Extrusion in one direction:
a) without slope, b) slope outward, c) slope inward

Fig. 2.3.15. Extrusion in both directions with different slope parameters

2.3.2.7. Thin Wall

You can create thin wall shell during creation of extrusion, revolution, lofted, swept features and some other objects.

When a shell is formed, a material layer is added to the feature surface (without its "end edges").

If construction of a thin wall shell based on a complex body surface (not a feature) is required, use the **Thin Wall Shell** command (see Section 2.3.8.3 on p. 196).

Options to control the construction of a thin wall feature are available during feature parameter setting. They are located on Properties toolbar **Thin Wall** tab.

Specify the direction of adding a material layer relative to the surface. To do this, select the required option in **Thin Wall Construction Type** list (see Table 2.3.3).

Tab. 2.3.3. Possible options for constructing a thin wall

	Value of Thin Wall Type option	Direction of adding a material layer. Specifics of defining wall thickness
	No	The thin wall is not created, i.e. body element is constructed. This option is available, if the section is a closed sketch (when performing rotation and extrusion operations, construction of a body feature is also possible using other objects as the section, see Sections 2.3.2.3.1 on p. 154 and 2.3.3.3.1 on p. 168).
	Outside	In the forward direction relative to the surface [*] . Enter the thickness in the Wall Thickness 1 field. Only positive values are allowed.
	Inside	In the backward direction relative to the surface [*] . Enter the thickness in the Wall Thickness 2 field. Only positive values are allowed.
	Two directions	In both directions relative to the surface. Enter in the Thickness of Wall 1 field thickness in the outward direction, in the Thickness of Wall 2 field— thickness in the inward direction (Fig. 2.3.16, a). One of the values may be negative. Negative thickness is calculated in the direction which is opposite to the positive one. This means removal of the material. Therefore, you can construct a thin wall at a distance from the element's surface (Fig. 2.3.16, b).
	Middle plane	In both directions symmetrically relative to the surface. Enter the overall thickness in the Wall Thickness 1 field. Only positive values are allowed.

* Use a ghost for visual control to direct adding of material.

Fig. 2.3.16. Construction of thin wall in both directions (on an extrusion feature example; section is shown with a thickened line): a) wall 1 thickness and wall 2 thickness are positive; b) thickness of wall 2 has not changed, while thickness of wall 1 has been attributed the opposite sign

Fig. 2.3.17. Examples of thin wall features

Word "thin" in the term "thin wall" is mostly a relative term. In some cases, you can add to the surface created by the contour movement a layer of material with such thickness that largely exceeds linear sizes of the contour in the sketch. The resulting feature will not be "thin-layer" in the direct sense of the word. However, in most cases, the thickness of the created feature is one or even several times less than its external dimensions, and this is why the wall is called a "thin" one.

For side walls of the thin wall extrusion feature with a slope, the specified thickness shall be complied in the section plane and in parallel planes.

2.3.2.8. Operation result

The result of the operation is:

- ▼ When adding material: **an individual body** or a **feature attached** to an existing body (bodies). When attaching, you can specify operation application area—a set of bodies with which a new element shall be merged.
- ▼ When removing material: **feature subtraction** from body (bodies) or **feature intersection** with body (bodies). When subtracting or intersecting, you can set the area to which the operation will be applied—a set of bodies and/or components whose material is to be removed as a result of the operation.

Operation result selection is described below, setting of operation application area—in section 2.3.10 on p. 217.

2.3.2.8.1. Result of adding material

When performing extrusion, rotation, by sections, sweeping, as well as when creating a sheet body and adding thickness, you can specify if the element should be a separate body or it should be joined with existing ones (i.e. to attach them to it).

Fig. 2.3.18. Selecting the result of adding material operation

To choose adding material option, go to the **Operation Result** tab of the Properties bar (Fig.2.3.18) and activate the desired switch in the **Operation Result** group.

- ▼ **Auto Union**— operation result is defined automatically. In this case, the construction is done as follows:
 - ▼ If the feature being created does not intersect and has no common surfaces with any of the existing bodies, then a new body is created,
 - ▼ If the created feature intersects or has a common surface with some of the existing bodies, then the feature is merged with those bodies.

- ▼ Activate the **New Body** switch to have the feature being created as a separate body regardless of whether it intersects other bodies or not.

- ▼ Activate the **Merge** switch to select arbitrary bodies to merge with the element being created. You can use the **Application Area** group of switches to select bodies (see Section 2.3.10.3.3 on p. 221). If an element is joined with one body, the total number of bodies in the model will not change. If the element is joined with several objects, the total number will decrease, since all joint bodies become parts of a new body.

By default, the **Auto Union** switch in **Operation Result** group is active. Note that this switch is only available when an operation is being performed. To verify this, enter the editing mode of the feature created with the **Auto Determination** switch enabled. You will see, that depending on operation result, **New Body** or **Union** switch is active on the Properties bar. In the latter case, the **List of Bodies** containing names of bodies with which there are intersections will appear on the Properties bar.

2.3.2.8.2. Result of material removing

When cutting a feature of extrusion, revolved, loft, or sweep type out of a model, material can be deleted inside or outside the feature surface, that is, the result can be the model less the feature or the model intersection with the feature (see diagram in Fig.2.3.19).

Fig. 2.3.19. Different methods of cutting: a) initial features, b) result of subtracting feature B from feature A, c) result of intersecting between features A and B

To select a cutting option, activate the **Cut** Properties toolbar tab (Fig. 2.3.20).

Fig. 2.3.20. Selecting the result of removing material operation

Activate the switch corresponding to the required method of cutting in the **Operation Result** group, i.e. **Subtraction of Feature** or **Intersection of Features**.

Fig. 2.3.21. Different methods of cutting: a) initial features, b) result of subtraction of cylinder from hemisphere, c) intersection of cylinder and hemisphere

2.3.3. "Rotation" and "Cut with rotation" operations

2.3.3.1. Revolution Feature

Revolution feature is created by rotation of section about the axis in either one or both sides at the specified angle. For example, a feature shown in Fig. 2.3.22, is created by rotating a sketch about an axis lying in its plane at 270°.

Fig. 2.3.22. Sketch, axis and element produced by the revolved operation

Rotation element may be an individual body or may be attached to a body or cut out of it.

Operation **Revolve** serves to create a new body of revolution or to add a revolution feature to an existing body (i.e. to add a material), operation **Cut-Revolve**— to cut a revolution feature from a body (to remove material).

A face, sketch, edge or 3D curve (including contour constructed by sketch lines, by face edges or arbitrary¹) may be used as a section of revolution feature.

During revolution of face, closed sketch, closed **Contour on Face** or **Sketch Contour**, the choice between thin wall and body feature is available. (Fig.2.3.23). If section is open, only thin wall feature construction is available.

Fig. 2.3.23. Face Rotation: a) section and axis, b) body feature, c) thin wall feature

If the section is an open sketch or an open contour built by the sketch lines or flat face's edges and rotates around the axis within the section's plane, the construction type selection is available— toroid or spheroid (Fig.2.3.5). When building a spheroid, a choice between body and thin wall feature is available. Toroid may be thin wall only.

During edge or 3D curve revolution (including contour of **Arbitrary** type), only thin wall feature construction is possible. Example of 3D curve revolution is shown in the Figure 2.3.6.

1. It means that has **Contour on Face**, **Sketch Contour** and **Arbitrary Contour** type, see Section 2.5.4.24.1 on p. 438.

Fig. 2.3.24. Spheroid and toroid construction (section— sketch— marked with a thickened line):
a) a solid spheroid, b) a thin-wall spheroid, c) a toroid

Fig. 2.3.25. Rotation element with a spiral section

2.3.3.2. Execution of the operation

1. Start an operation. To do this, complete the following steps:

▼ click the required button on the **Edit Part** or **Edit Model** panel.

▼ or call the required command from **Operations** menu.

Availability condition of **Cut-Rotate** command: model including a body or a component.

After operation launch, tabs with operation parameters controls appear on the Properties bar.

2. Specify the operation parameters:

▼ **Section** (see Section 2.3.3.3).

▼ **revolution axis** (see Section 2.3.3.4);

▼ **creation type** (see Section 2.3.3.5);

▼ **revolution direction** (see Section 2.3.3.6);

▼ **revolution angle** (see Section 2.3.3.7).

▼ **Thin Wall Settings** (see Section 2.3.2.7),

▼ **Result** (see Section 2.3.2.8).

All parameter values, once entered or modified, are immediately displayed on the screen as the ghost of the extruded feature. A ghost allows a visual control over parameter accuracy.

You can use handles to specify rotation angle and wall thickness (for more on handle see Section 2.1.4.2.2 on p. 138).

3. Click **Create Object** button to complete the operation.

4. If such operation results in a body comprising several parts, the Modify set of parts process will be started automatically after the end of the operation. Select the parts to be hold (see Section 2.3.11.1 on p. 226).

Operation result — new body, pasted or cut element — appears in the graphic area.

The operation's icon will appear in the Design Tree matching the icon on the command's button which is used to run the operation. Exception is an icon of new revolution body—it differs from an icon on the button.

— an icon of new revolution body

2.3.3.3. Section of revolution element

2.3.3.3.1. Dependence of the result of revolution operation of the section

In Table 2.3.4, you can see peculiarities of the revolution operation's performance and results depending on the choice of section.

Tab. 2.3.4. Peculiarities of revolution operation depending on an object used as a section

Object	Peculiarities of operation execution and result
sketch, face, contour constructed by sketch lines or by face edges	<ul style="list-style-type: none"> ▼ Construction Type Selection — toroid or spheroid (see Section 2.3.3.5 on p. 170) — is available if the following conditions are satisfied: <ul style="list-style-type: none"> ▼ a section is open and represents a sketch or contour constructed by sketch lines or by flat face edges, ▼ revolution axis lies in the section plane. ▼ If section is closed, you can create both thin wall and body feature. If section is open, you can choose between a thin-wall or solid element when creating a spheroid; in other cases, a thin-wall element will be constructed when the section is open. ▼ Sketch must satisfy the requirements presented in Section 2.3.3.3.3.
edge, 3D curve, arbitrary contour	<ul style="list-style-type: none"> ▼ only thin wall feature can be created ▼ unavailable to select type of construction— toroid or spheroid

2.3.3.3.2. Setting of the Revolution Feature Section

You can use an existing object in the model as a section of the rotation element— an edge, curve, sketch or face, or you can create a new object — contour — without interrupting the operation.

To select the existing object as a section, specify it in the Design Tree or in the graphic area.

To create a contour, click the **Contour** button on the Advanced control panel. Contour creation process will be started (see Section 2.5.4.24 on p. 437). Specify objects included into contour and click **Create Object** button. The system will resume the revolution operation process, created contour will appear in the Design Tree and will be automatically selected as a revolution feature section.

Name of the section object shall appear in the **Section** field on Properties toolbar.

If, when rotating section around the chosen axis, two or more section points have the same paths, it will not be possible to complete the operation. You need to change section or axis.

Revolution feature section can be specified before the operation launch.

You can change revolution feature section at any time. To do this, activate **Section** switch and then specify the desired objects or construct a contour.

A sketch selected as an revolution feature section can be edited without interrupting the operation. To do this, click the **Edit Sketch** button on the Special Control Panel. The system will switch to the sketch editing mode. Make the necessary modification in the sketch. Then click **Sketch** button on the **Current status** panel or click the sketch mode icon in the document window to return to the rotation operation process.

2.3.3.3. Revolution Feature Sketch Requirements

- ▼ Sketch objects can be a part of one or several contours.
- ▼ If there are several contours, they all should be either closed or open.
- ▼ If the contours are closed, they can be nested. The level of nesting is not limited.

Besides the section, sketch may also contain the rotation axis. In this case, additional requirements shall be met:
- ▼ the axis should be drawn in a sketch as a line segment with *Centerline* line style or as an *Centerline* object type,
- ▼ no contour should intersect the axis (or its extension),
- ▼ some contour points may be on the axis (or its extension),
 - ▼ for closed contours – any of their points and/or segments,
 - ▼ for open contours – only their outermost points.

2.3.3.4. Revolution Axis,

To specify revolution axis, you can:

- ▼ select an existing object:
 - ▼ straight-line object (edge or axis) — the object will be used as axis,
 - ▼ rotation surface (except for the sphere) — the surface rotation axis will be used,
- ▼ construct auxiliary axis.

The axis of revolution may be defined automatically. For this purpose, it should be present in the same sketch with the element's section and be a segment with the *Axial* type or the *Axial line* object. If necessary, you can select another axis.

To select a straight-line object or revolution surface, activate **Axis** switch on the Properties bar and then specify the required object in the Design Tree or in the graphic area.

To create an axis, click the **Axis through Vertex to Object** button on the Special Control Panel. Axis creation process will be started (see Section 2.8.1.5 on p. 588). Create the axis and click the **Create Object** button. The system will resume the revolution operation process, created axis will appear in the Design Tree and will be automatically selected as a revolution axis. The name of the axis-setting object will appear in the **Axis** field.

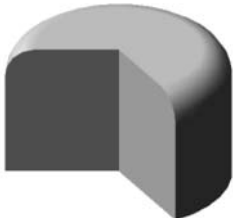

2.3.3.5. Construction type

Construction Type Selection — toroid or spheroid — is available, if:

- ▼ a section is open and represents a sketch or contour constructed by sketch lines or by flat face edges,
- ▼ revolution axis lies in the section plane.

To select the right building type, activate the applicable switch in the **Method** group (see Table 2.3.5).

Tab. 2.3.5. Types of revolution feature

Value of Type option	Aspects of feature construction	Construction result
 Toroid	<p>When building a toroid, only the section itself is revolved. A layer of material is added to the generated surface. Therefore, a thin-wall shell appears, i.e. a feature with a hole along the axis of revolution. Setting of a thin wall is detailed in Section 2.3.2.7.</p>	
 Spheroid	<p>When building a spheroid, the section end points are projected onto revolution axis. The feature is then built considering these projections. Consequently, you get a body feature.</p>	

If you need to build a rotation element with flat edges (Fig. 2.3.26), create a section with the profile of this element and activate the **Spheroid** switch when performing the operation.

Fig. 2.3.26. Construction of a revolution feature with plane end edges

2.3.3.6. Direction of Revolution

Direction of revolution can be selected from the **Direction** list (see Table 2.3.6).

Tab. 2.3.6. Available directions of extrusion

	Value of Direction option	Direction of the revolution. Aspects of revolution angle setting
	Forward	In the forward direction relative to the section*. When choosing this option on the property bar, there is the Method 1 list to select a method of setting the rotation angle (see Section 2.3.3.7).
	Reverse	In the reverse direction relative to the section*. When choosing this option on the property bar, there is the Method 2 list to select a method of setting the rotation angle (see Section 2.3.3.7).
	Two directions	In both directions relative to the section. When choosing this option on the property bar, there are Method 1 and Method 2 lists to select a method of setting the rotation angle in each direction (see Section 2.3.3.7).
	Middle plane	To both directions symmetrically relative to the section. If this option is selected, Method 1 and Method 2 lists are unavailable, for only one method to define the angle, i.e., the exact setting of overall rotation angle, is available. Enter the required value into the Angle 1 .

* For distinguishing directions (forward and reverse), the ghost in the detail viewing window has an arrow indicating the forward direction. If **Forward Direction** option is selected, revolution shall be done in the direction of the arrow. If **Reverse Direction** option is selected, the revolution shall be done against the arrow.

2.3.3.7. Rotation Angle

Once the direction is selected, you need to specify the angle revolution value. To do this, select the desired option from **Method 1** (and/or **Method 2** — depending on the selected rotation direction) list on the Properties bar. The list of methods of defining the rotation angle contains the following options (they are described below):

▼ **At angle,**

▼ To vertex,

▼ To surface.

2.3.3.7.1. Rotation by the specified angle

Section rotation is done exactly by the angle specified in the **Angle** field.

Fig. 2.3.27. Rotation by the specified angle

2.3.3.7.2. Rotation up to vertex

The section rotation angle is defined automatically by position of a vertex selected by user.

Fig. 2.3.28. Rotation up to vertex

- ▼ If a face, sketch, or contour built by sketch lines or face's edges, are used as a section, the rotation angle is calculated so that the element's endface (or its continuation) goes through the specified vertex.
- ▼ If an edge, 3D curve, or an arbitrary contour is used as a section, the rotation angle is defined as follows: In the plane, perpendicular to the axis, a circle is built, with its center on the axis, going through the specified vertex. A point nearest to the section is placed on this circle. The section's rotation angle is accepted as equal to the angle of the arc between the identified point and the specified vertex.

To specify a vertex defining rotation angle, activate **Vertex** switch on the Properties bar and select the desired point object in a graphic area (point can be also specified in the Design Tree). The name of the selected object is displayed in a field beside the switch.

Cut option allows to cut revolution feature by a plane going through the selected vertex and revolution axis. In this case, the element will have a flat endface irrespective of the section form.

Extension of complex shape faces is not always possible. Therefore, if the specified vertex is positioned in such a way that, provided the rotation axis is set, the element's endface does not go through the vertex, in some cases, construction will only be possible if the **Cut** option is enabled.

2.3.3.7.3. Revolution up to surface

The rotation angle is defined automatically by position of a face or a plane specified by User.

Fig. 2.3.29. Revolution up to surface

To specify the active surface, enable the **Face** switch and select the desired face or plane in the Design Tree or in the graphic area.

The element is rotated up to the selected surface. The endface of the feature has the surface form.

It is recommended to choose section, axis, and surface so that the surface fully intersects the rotation element. Otherwise, the construction is done only in case of selected surface can be extended. Extension of complex shape surfaces is not always possible.

2.3.4. Sweep and Cut-Sweep operations

2.3.4.1. Swept feature

A swept feature is created by sweeping section along the path, for example, as in Fig. 2.3.30.

Fig. 2.3.30. Section, guide and swept feature

Swept element may be an individual body or may be attached to a body or cut out of it.

Operation **Sweep** is used to create a new sweep body or to add a swept feature to an existing body (i.e. to add a material), operation **Cut-Sweep**— to cut a sweep feature from a body (to remove material).

2.3.4.2. Carrying out of Sweep Operation

1. Start an operation. To do this, complete the following steps:

▼ press the required button on the **Edit Part** or **Edit Model** panel.

▼ or call the required command from **Operations** menu.

Condition of availability of commands **Sweep** and **Cut-Sweep**: at least one sketch in the model. Additional availability condition of **Cut-Sweep** command: model including a body or a component.

After operation launch, tabs with operation parameters controls appear on the Properties bar.

2. Specify the operation parameters:

- ▼ **section** (see Section 2.3.4.3);
- ▼ **path** (see Section 2.3.4.4);
- ▼ **type of section movement** (see Section 2.3.4.5);
- ▼ **thin wall settings** (see Section 2.3.2.7),
- ▼ **result** (see Section 2.3.2.8).

All parameter values, once entered or modified, are immediately displayed on the screen as the ghost of the extruded feature. A ghost allows a visual control over parameter accuracy.

You can use handles to specify wall thickness (for more on handle see Section 2.1.4.2.2 on p. 138).

3. Click **Create Object** button to complete the operation.
4. If such operation results in a body comprising several parts, the Modify set of parts process will be started automatically after the end of the operation. Select the parts to be hold (see Section 2.3.11.1).

Operation result — new body, pasted or cut element — appears in the graphic area.

The operation's icon will appear in the Design Tree matching the icon on the command's button which is used to run the operation. Exception is an icon of the new swept body — it differs from an icon on the button.

— an icon of new swept body

2.3.4.3. Section of swept feature

A sketch is used as a section of swept feature. Requirements to the sketch are specified in Section 2.3.4.3.1.

To specify the swept feature section, activate the **Section** switch and select the required sketch in the Design Tree or in the graphic area.

Name of the selected sketch shall appear in the **Section** field on Properties toolbar.

Section can be specified before the operation launch.

2.3.4.3.1. Section sketch requirements

- ▼ Section sketch objects should comprise one contour.
- ▼ A contour can be closed or open.

2.3.4.4. Path of swept feature

The following may be used as a path of swept feature:

- ▼ 3D curve (or separate segment of multi-segment curve),
- ▼ a sketch line,
- ▼ an edge,
- ▼ Chain of objects listed above in any combination.

To set the path of section movement, activate \dots switch. Then, in the Design Tree or in the graphic area, specify the desired objects in the order they are connected.

The name of the selected object or the number of selected objects are shown in the **Path** field on the Property Bar.

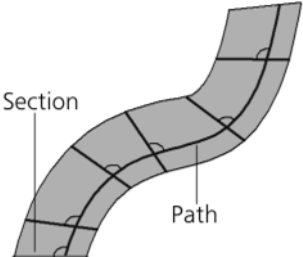

2.3.4.4.1. Path requirements

- ▼ A path can be closed or open.
- ▼ If path is open, its start point or end point should lie in the plane of the section sketch.
- ▼ If path is closed, it should intersect a plane of the section sketch
- ▼ A tangent to the path in its point common with the sketch plane should not be on the same plane.

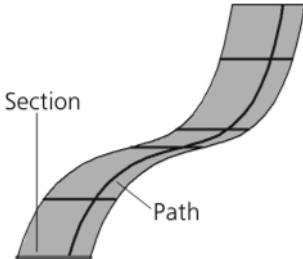

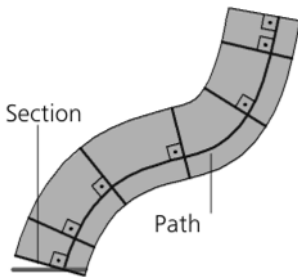

2.3.4.5. Type of Section Movement

While the sketch is being moved along the path, its orientation can be changed or kept the same. To specify the required type of section movement, activate the applicable switch in **Section Movement** group (see Table 2.3.7).

Tab. 2.3.7. Variants to change the section orientation during sweep

Switch in Section Movement group	Specifics of feature construction	Feature construction procedure
 Maintain Slope*	<p>When this option is selected, the section is swept at a constant angle to the path at any point along the feature equal to the angle between the original section sketch and the path at its start point.</p>	

Tab. 2.3.7. Variants to change the section orientation during sweep

	Switch in Section Movement group	Specifics of feature construction	Feature construction procedure
	Parallel to itself**	Section is moved in such a way that its plane remains parallel to the plane of the sketch containing this section at any point of the path.	
	Orthogonal to Path*	Section is moved in such a way that section plane remains perpendicular to the path at any point of the path.	

* If the plane of section sketch is perpendicular to the path in its initial point, then the **Maintain Slope Angle** and **Orthogonally to Path** options shall provide the same construction result.

** Carrying out section movement parallel to itself is not allowed if the path has points where a tangent to the path is parallel to the sketch section plane.

Fig. 2.3.31 shows construction of the swept feature under different section orientation relative to the path. Initial position of the sketch and the path are the same in all cases, but the results of construction are different.

Fig. 2.3.31. Swept feature: a) sketches of section and the path, b) movement of the section with the slope angle maintained, c) movement of the section parallel to itself, d) movement of the section orthogonal to the path.

2.3.5. By Sections and Cut-Sections operations

2.3.5.1. Lofted Feature

Element by sections is created by connection of several sections of arbitrary shape and position, for example, as in Fig. 2.3.32. Extreme section can be a point.

Fig. 2.3.32. Sections and element created using them

If necessary, you can use a centerline during element creation by sections (see Fig.2.3.33).

Lofted element may be an individual body or may be attached to a body or cut out of it.

Operation **Loft** serves to create a new lofted body or to add a lofted feature to an existing body (i.e. to add a material), operation **Cut-Loft**— to cut a lofted feature from a body (to remove material).

2.3.5.2. Execution of the operation

1. Start an operation. To do this, complete the following steps:

▼ click the required button on the **Edit Part** or **Edit Model** panel.

▼ or call the required command from **Operations** menu.

Condition of availability of commands **Loft** and **Loft-Cut**: at least two sketches in the model. Additional availability condition of **Cut-Loft** command: model including a body or a component.

After operation launch, tabs with operation parameters controls appear on the Properties bar.

2. Specify the operation parameters:

- ▼ **Section**, see Section 2.3.5.3;
- ▼ **Centerline** (see Section 2.3.5.4);
- ▼ **Element Construction Method near Extreme Sections**, see Section 2.3.5.5;
- ▼ **The Path of Sections Connection** (see Section 2.3.5.6);
- ▼ **Thin Wall Settings** (see Section 2.3.2.7),
- ▼ **Result** (see Section 2.3.2.8).

All parameter values, once entered or modified, are immediately displayed on the screen as the ghost of the extruded feature. A ghost allows a visual control over parameter accuracy.

A thin-wall loft feature can be created only if all its sketched sections contain contours. Such a feature cannot be created using point-containing sketches.

You can use handles to specify wall thickness (for more on handle see Section 2.1.4.2.2 on p. 138).

3. Click **Create Object** button to complete the operation.
4. If such operation results in a body comprising several parts, the Modify set of parts process will be started automatically after the end of the operation. Select the parts to be hold (see Section 2.3.11.1 on p. 226).

Operation result — new body, pasted or cut element — appears in the graphic area.

The operation's icon will appear in the Design Tree matching the icon on the command's button which is used to run the operation. Exception is an icon of new body by sections— it differs from an icon on the button.

— an icon of new lofted body

2.3.5.3. Sections of lofted feature

During lofted feature construction, sketches are used as a sections. Requirements to the sketches are specified in Section 2.3.5.3.1.

To specify the swept feature sections, activate the **Sections** switch and select the required sketches in the Design Tree or in the graphic area.

The list of sketches appears in the **Sections List** window in the order they were selected. The sections will be connected in this order when building the feature. To change the order of sections or delete some of them, use the buttons above the list.

While selecting sections in the feature window, indicate them in points (vertices) which shall be connected in sequence. In this case, when path is generated automatically (see Table 2.3.9), body of the required form will be built.

Sections can be specified before the operation launch.

2.3.5.3.1. Section sketch requirements

- ▼ Sketches can be positioned on arbitrarily oriented planes
- ▼ Every sketch objects should comprise one contour.
- ▼ Extremely (initial and final) located sketches may contain only one point (instead of a contour)
- ▼ The contours should all be either closed or open.

2.3.5.4. Centerline of lofted feature

If necessary, you can specify a centerline during lofted feature creation. Examples of elements built using the same sections with a center line and without it are shown in Fig.2.3.33.

Fig. 2.3.33. Loft features: a) without centerline; b) with centerline

The following may be used as a centerline:

- ▼ a 3D curve,
- ▼ sketch,
- ▼ edge.

Centerline must satisfy the requirements presented in Section 2.3.5.4.1.

To specify the feature centerline, activate the **Centerline** switch and select the required object in the Design Tree or in the graphic area.

2.3.5.4.1. Centerline requirements

- ▼ Axis can be open or closed
- ▼ If the axis is open, its end points shall lie in planes of the first and the last section sketches
- ▼ If the section contours are open, the axis shall intersect the planes of section sketches in the points belonging to these contours. If section contours are closed, intersections within contours are acceptable.
- ▼ A tangent to the centerline in its point common with the sketch plane should not be on the same plane.
- ▼ If the centerline is a multi-segment one (for example, contour containing several curves), its segments must be connected tangentially or smoothly.

2.3.5.5. Method of Constructing a Feature near Extreme Sections

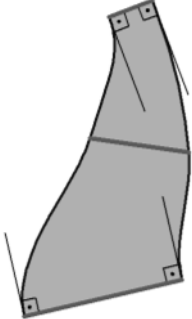

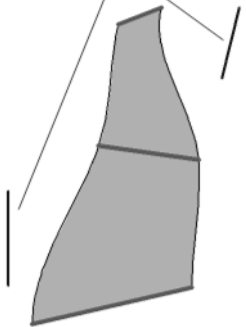

You can specify a direction of feature tangents going through the points of contours in its extreme sections. In other words, you can change the direction of feature “exit” from the first section and the direction of “entrance” into the last section. To do this, select the required option in **Initial Section** and **Final Section** list accordingly (see Table 2.3.8).

Tab. 2.3.8. Methods of constructing a feature by the initial and final section

Switch in Path group	Aspects of element construction	Feature construction procedure
By default	Selected vertices of the sections shall be connected by splines of third degree.	

Tab. 2.3.8. Methods of constructing a feature by the initial and final section

Switch in Path group	Aspects of element construction	Feature construction procedure
By Normal	The feature forms in such way that the plane tangent to its surface near the border (the first or the last one) section becomes perpendicular to its plane.	
By Object	The feature forms in such way that the plane tangent to its surface near the border sketch becomes parallel to the specified straight-line object or perpendicular to the specified planar object. To specify an object, activate the Vector of Initial (Final) Section switch and select the desired object in the Design Tree or in the graphic area.	Objects defining out of line sections: 

2.3.5.6. The Path of Sections Connection

The same sections can be connected by different methods. You can select a path generation method, as well as make it open or closed.

2.3.5.6.1. Method of Path Generation

Section points to be connected during element construction may be specified manually or defined automatically. To select the required variant, activate the applicable switch in **Path** group (see Table 2.3.9).

Tab. 2.3.9. Variants of path generation

Switch in Path group	Aspects of feature construction
 Automatic Path Generation	Section points to be connected during element construction are set automatically. This method is recommended if the topology of sections is the same (Fig.2.3.34).

Tab. 2.3.9. Variants of path generation

 Switch in **Path** group Aspects of feature construction

Path Generation by specified points Sketches are sequentially connected by points nearest to the points of their selection (Fig.2.3.35).

Fig. 2.3.34. Automatic connection of sections

Fig. 2.3.35. features generated by connecting different points of similar sections (the connected points are highlighted)

If sketches are selected in the Construction Tree, the automatic path-generating algorithm is used.

If sections are not convex, select the path manually.

If topologies of sections differ significantly (i.e., one of them is a triangle, and the other one is a pentagon), the result of construction may not correspond to the expected result: the feature may be “coiled”, or additional edges may emerge (Fig.2.3.36).

To fix the above mentioned error, edit the sections as follows:

1. Identify the section whose contour contains the largest number of segments, i.e. geometrical objects (straight line segments, arcs, splines). Determine this number.
2. Divide geometrical objects in other sections to satisfy two conditions:

Fig. 2.3.36. Automatic connection of sections with different topology

- ▼ Each section shall have the same number of segments, i.e. geometrical objects. It shall be equal to the number defined in the item1.
- ▼ The splitting points shall lie on the presumed edges of the loft.

For methods of dividing geometric objects, see Section 3.4.6 on p. 1136.

The resulting feature based on modified sections is shown in Fig.2.3.37.

Fig. 2.3.37. The arc in the upper section is divided into three mating parts.

As a result, the contour in the section has not changed, while construction result has become predictable

2.3.5.6.2. Closed or Open Path

To select an option for path construction, activate **Open** or **Closed** switch in **Mode** group.

Upon constructing a closed path, sections specified as the first and the last shall become connected.

If centerline (see Section 2.3.5.4 on p. 179) is not in use, **Mode** group is available if more than two sections are selected.

If a centerline is selected in addition to sections, then the **Mode** group is inaccessible. At the same time, the active switch is left set to the axis configuration.

Fig. 2.3.38. Open or closed features constructed by the same sections

If a feature is closed, the method to construct it incorporating all sections shall be **By Default** (see Section 2.3.5.5).

2.3.6. Thickening a surface or body face

You can thicken body faces or a surface, i.e. add a material layer to these faces. Faces selected for thickening may belong to either objects of the model itself, or those of its components.

For adding a material layer, use the **Thicken** command.

The command is accessible if there is at least one surface, body or component.

Fig. 2.3.39. Thickening a surface face:
a) the initial face, b) adding a material layer in one direction

The following objects may be used as source ones:

- ▼ face of the body or surface,
- ▼ a connected set of faces of one body or surface.

If you want to add a material layer to all faces or to the entire surface, this body or surface must be selected in the Design Tree.

Select the source object.

The source objects for adding material can be also selected before calling the command.

The second selection of a face cancels it's selection.

If you need to change all the objects to be thickened, click the **Reselect** button on the Special Control Panel and then reselect the objects.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

After the source objects are specified, there will be displayed the ghost of the added layer and the thickness control handles.

Specify thickness of the added layer. It is made in a similar way as when setting up thin wall parameters (see Section 2.3.2.7 on p. 161), with the only exception that: you can not cancel the construction of thin wall by clicking **No** option.

If necessary, customize the operation application area using the controls of the **Operation Result** tab on the Property Bar (see Section 2.3.10.3.1 on p. 220).

The construction is impossible in the following cases:

- ▼ the added material layer is a body with damaged topology, i.e. with breaks or the surface parts degenerated into a point or line;
- ▼ the surface of the added layer intersects itself;
- ▼ when several faces are specified, the intersection of their equidistant surfaces can't be defined uniquely.

Click the **Create Object** button to fix the added material.

The created feature will appear in the model window and the applicable icon will appear in the Tree.

The operation results in the material layer restricted with the initial surface and equidistant to it or with two equidistant surfaces.

It is impossible to thicken faces of a body which consists of several parts. You must first make the body integral by editing the existing elements or by creating new elements to connect the parts.

2.3.7. Boolean operation applied to bodies

Serves to perform a Boolean operation on two bodies present in the current model. Bodies involved in the operation may belong to either the model itself, or its components. The result of the Boolean operation is a new body that belongs to the current model. This body may be used in any future operations, including the Boolean ones.

The command is available if there is more than one body in the part.

To call the command, click the **Boolean Operation** button on toolbar for editing the model or select its name from **Operations** menu.

Fig. 2.3.40. Properties toolbar during Boolean operation execution

Select the first and the second body involved in the operation.

Selected bodies are highlighted in the Model window. Their respective icons will be highlighted in the Design Tree. The names of the objects belonging to bodies are displayed in the **List of Objects** on the **Settings** tab of the Properties toolbar (Fig. 2.3.40).

If you need to cancel the selection, click the **Reselect** button on Special control panel. Highlighting of all selected bodies will be cancelled, and you will be able to select the new ones.

If only the second body was selected incorrectly, simply select the desired one without cancelling the previous selection.

Define the Boolean operation type using the **Operation Result** switch group.

Activate the **Union** switch to merge the selected bodies.

To delete the first body volume portion which is occupied by the second body, activate the **Subtraction** switch. The body appearing first in the list is considered to be first, the body positioned second is considered to be second.

To change the sequence of bodies, use **Move down** and **Move up** buttons on the **List of bodies** panel.

To delete all volume of both bodies except for their common volume, activate the **Intersection** switch.

Bodies can be merged if they intersect or have a common surface, whereas subtracting and intersecting are possible only if bodies intersect.

The object name, i.e., the name displayed in the Design Tree, can be defined on the **Properties** tab of Properties panel.

When you have set the operation parameters, click the **Create Object** button on the Special Control panel.

The Design Tree will show an icon of a Boolean operation, and in the window of part the body being the operation result will appear.

A Boolean operation of subtraction or intersection of bodies can result in a body made up of multiple pieces (see Section 2.3.11 on p. 224).

2.3.7.1. Display of the Boolean operation on the Design Tree

Fig. 2.3.41 presents examples of displaying Boolean operations on the Design Tree for bodies on various levels of the model's structure.

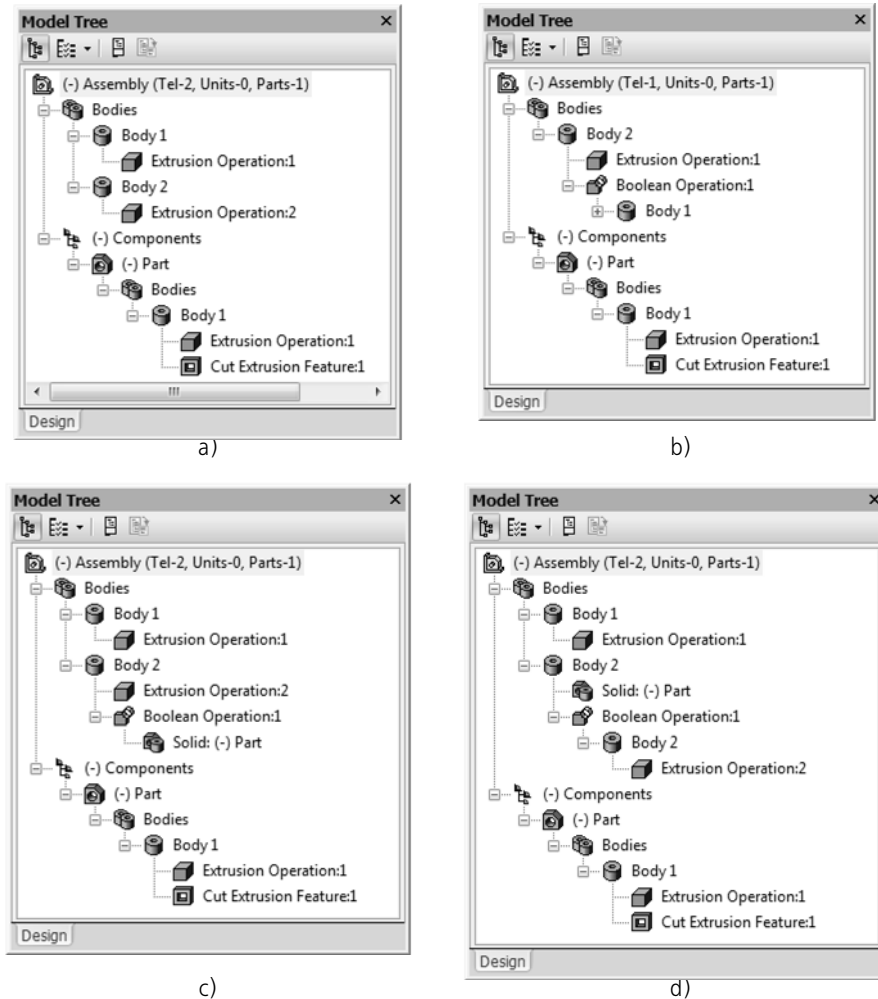

Fig. 2.3.41. Displaying Boolean operations on the Design Tree: a) initial state of the model, b) Boolean operation on bodies belonging to the model, c) operation on a body belonging to the model (specified as the first) and a body belonging to the component (specified as the second), d) the same, but the order of specifying the bodies is reverse

2.3.8. Body editing operations

Functionally, KOMPAS-3D has taken into account the specific engineering drafting work techniques. The system is targeted at producing models of certain parts containing typical structural features, which simplifies performing certain specific operations. These operations include, for example, creating a chamfer, a rib, etc.

To simplify the process of defining parameters for those features, dedicated commands are provided for creating them. Thus, to create a chamfer, you do not have to draw a sketch, sweep it along an edge and subtract the resulting volume from the main body. It is sufficient to select

chamfer edges and then enter its parameters, i.e. the lengths of the sides or a side length and an angle.

Commands to create structural features are placed in **Operations** menu.

To specify numerical parameters of additional structural features, you can use handles (see Section 2.1.4.2.2 on p. 138).

Editing operations apply both to bodies built within the model itself, and those built within components.

2.3.8.1. Chamfer

To create a chamfer on the part edges, apply **Chamfer** command.

The command is not performed on edges created by smoothly adjoining faces.

Select a method to construct a chamfer— **By Side and Angle** or **By Two Sides** by activating the corresponding switch in **Method of Construction** group.

- ▼ If a chamfer is created by a side length and an angle, enter the chamfer side length in the **Length 1** field, and in the **Angle** field the angle between the side and the chamfer surface. The calculated value of the chamfer's second side shall appear in the **Length 2** reference field.

- ▼ If a chamfer is created by two side lengths, enter their values in the **Length 1** and **Length 2** fields. The calculated value of the chamfer's angle shall appear in the **Angle** reference field.

Select edges to create a chamfer in the Part window. If you need to create chamfers on all edges of a face, select that face.

Upon selecting the first edge, a ghost chamfer is displayed in the Part window together with an arrow pointing along one of the faces. The arrow indicates direction in which the chamfer side with **Length 1** length shall be plotted. The chamfer angle shall be plotted relative to this direction.

If changing the direction in which the first side is to be plotted is required, activate the applicable switch (**First Direction** or **Second Direction**) in group **Direction of the first side**. The direction of the ghost arrow (hence, the direction of the chamfer's first side as well) shall change.

If sides of a chamfer are equal, then the result of it's construction shall not depend on the first side direction.

Do not create a chamfer for each edge individually. Specify as many edges with the same face parameters as possible while creating a chamfer.

You may find it difficult to follow this advice if a chamfer is not equilateral. If edges selected to construct such a chamfer do not belong to one face, then selecting a uniform chamfer direction for all edges may result in a wrong construction. In this case, we recommend selecting edges belonging to one face to construct a chamfer, and creating individual chamfers for each of the edges.

If several edges used to construct a chamfer are merged smoothly (have a tangent where they connect), select one of them and enable the **Extend Along Tangent Edges** option. In this case, the system will automatically determine other edges on which to extend the chamfer.

Once operation execution is complete, a chamfer shall appear on the edges of the part, and a chamfer icon— in Model Tree.

Create chamfers and fillets, wherever possible, at the end of part construction process, rather than immediately upon emergence of shape-generating features requiring creation of chamfers and fillets. In this case, the calculations during execution of shape-generating feature operations shall be performed faster.

2.3.8.2. Fillet

To round an edge (or several edges), apply the **Fillet** command.

The command is not performed on edges created by smoothly adjoining faces.

Select **Type of Fillet** — with constant or variable radius. By default, **Constant Radius** switch is enabled. If you need to create a variable-radius fillet, activate the **Variable Radius** switch.

Select the edges for filleting. If you need to fillet all edges limiting any face, select this face.

Fig. 2.3.42. Fillet: a) to construct fillet, the upper face is shown, option is enabled; b) result of fillet construction

Do not fillet each edge individually. If possible, select the most number of edges to fillet using the same radius. In this case, calculations will be run faster upon model rebuilding.

To create a fillet with constant radius, select its creation method and set its parameters (see Section 2.3.8.2.1 on p. 190).

To create a fillet with variable radius, set additional parameters on **Variable Radius** tab on Properties toolbar (see Section 2.3.8.2.2 on p. 192).

Activate the **Parameters** tab of the Property Bar and select corner capping and corner treatment methods (see Section 2.3.8.2.3 on p. 193).

If several edges to be filleted merge smoothly (are tangent at the connection), select one of them and enable the **Extend Along Tangent Edges** option on the Options tab of the Properties toolbar. In this case, the system will automatically determine other edges to which to extend the fillet.

Fig. 2.3.43. Fillet: a) to construct fillet, one edge is shown and **Continue by Tangent** option is enabled; b) result of fillet construction

The **Maintain Edge** option allows to create a fillet while maintaining the shape of neighboring face edges (see Section 2.3.8.2.4 on p. 194). The option is unavailable when creating the fillet with variable radius.

If you need to stop filleting at a certain point on the edge, activate the **Stop Filleting** tab and set parameters for the stopping point (see Section 2.3.8.2.5 on p. 195).

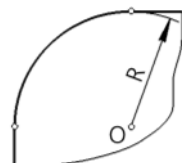

As soon as completion of operation is confirmed, part edges will be filleted and a fillet icon will appear in Design Tree.

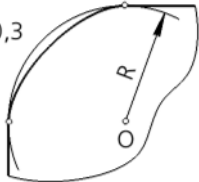

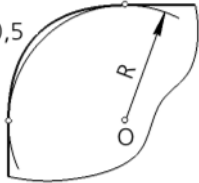

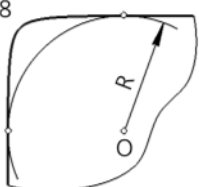

2.3.8.2.1. Fillet with Constant Radius

A fillet with constant radius can be created by four methods (Table 2.3.10). To select the right method, activate the corresponding switch in the **Method** group on the Property Bar.

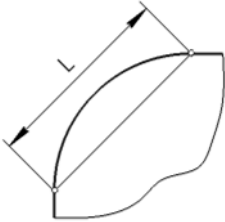

Tab. 2.3.10. Methods of creation of fillet with constant radius

Method	Construction result
 <p>With Circle Arc The fillet profile is a circle arc. Enter the required fillet radius in the Radius field or define it using the counter.</p>	

Tab. 2.3.10. Methods of creation of fillet with constant radius

Method	Construction result
	<p>With Elliptical Arc The fillet profile is an elliptical arc. Enter the required values of ellipse semiaxes (L1,L2) in the fields Semiaxis 1 and Semiaxis 2 or use the spinner to select them.</p>
	<p>With Factor The fillet profile is a conic curve. Enter the required values of fillet radius and of conic fillet curve factor K in the fields Radius and Factor or use the spinner to select them. The K value can vary from 0 to 1 ($0 < K < 1$). If the K factor value is more than 0 but less than 0.5 ($0 < K < 0,5$), the fillet profile is an elliptical arc.</p>
	<p>K=0,3</p> 
	<p>If the K factor value is equal to 0.5, the fillet profile is a parabola.</p>
	<p>K=0,5</p> 
	<p>If the K factor value is more than 0.5 but less than 1 ($0,5 < K < 1$), the fillet profile is a hyperbola.</p>
	<p>K=0,8</p> 

Tab. 2.3.10. Methods of creation of fillet with constant radius

Method	Construction result
 <p>With Constant Chord The fillet profile is a circle arc. Enter the required chord value in the Chord field or use the spinner to select it.</p>	

2.3.8.2.2. Fillet with a Variable Radius

To create a fillet with a variable radius, you need to define points on the edges being filleted and the filleting radii in these points.

A panel containing a table of fillet parameters of the same name is located on the **Variable Radius** tab. It includes point IDs, distances from them to the starting points of the respective edges and fillet radii values in these points (Fig.2.3.44, b). As long as the points to construct a fillet are not specified, the table of parameters is empty.

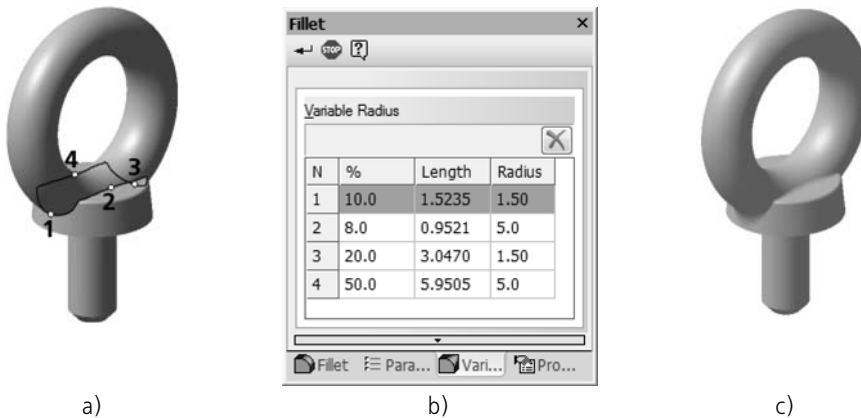

Fig. 2.3.44. Variable-radius fillet parameters: a) selection of points, b) fillet parameterization, c) command execution result

Select the desired points in the Model window. Selected points shall be marked with crosses and numbered in order of their selection (Fig.2.3.44, a).

In **Variable Radius** table, specify values of fillet radii in selected points.

If necessary, specify the values in **%** or **Length** column. Remember that changing of values in these columns moves the applicable point in the model window.

To change any value, click once or double-click in the required cell. Upon a single click, you can enter values in the cell by typing from the keyboard, upon a double click — by typing from keyboard or selecting by the stepper button.

You can delete the table row and, consequently, a point in the part preview window. To do this, click the  button placed over the list.

Setting of parameters of a fillet with a variable radius has the following specific features.

- ▼ By default, the fillet radius at the boundary edge points is equal to the default radius defined in the **Radius** field on the **Fillet** tab of the Property Bar. Boundary points of an edge are its start and end points. These correspond to 0% and 100% of the edge length. If a fillet radius at the boundary point has to differ from the default, select the point explicitly in the Model window and define the desired radius value in the Fillet parameters table.

If an edge is closed, then its start and end points coincide, and you can select just one of them when setting a fillet.

If two edges are selected to construct a fillet, where the end point of one of them coincides with the start point of another one, then you can select just one of them when setting the fillet.

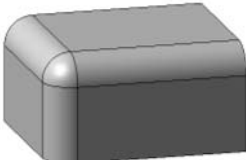

- ▼ The zero radius can be defined only at a fillet boundary points. If it is difficult to precisely select a boundary point of an edge in the Model window, then you can make a rough selection first, and then enter the desired value— 0% or 100%— in the respective entry of the Parameters table. Note that you cannot set a zero radius for a non-boundary point, nor can you change the distance from the vertex for a point with the zero radius (to do this, change the radius first).
- ▼ When rounding edges without specified points, the default value is used. For example, if the **Extend Along Tangent Edges** option on the **Parameters** tab of the Property Bar was enabled when creating a fillet with variable radius, such tangent edges will be automatically found by the system. Since it is impossible to specify points on them, those are filleted with the default radius.

2.3.8.2.3. Corner Capping and Treatment

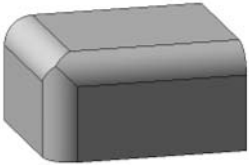

Capping and **Treatment** are fillet face joining methods.

The methods are selected on the **Parameters** tab of the Property Bar using the group of switches **Capping** and **Treatment**. Construction examples are presented in Tables 2.3.11 and 2.3.12.

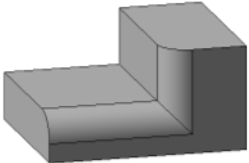

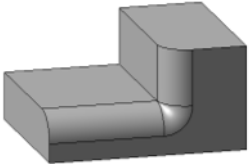

Tab. 2.3.11. Corner Capping Methods

Method	Construction result
 Smooth angles	

Tab. 2.3.11. Corner Capping Methods

Method	Construction result
 Don't smooth angles	

Tab. 2.3.12. Corner Treatment Methods

Method	Construction result
 Passing without smooth joining	
 Passing with smooth joining	

The **Treatment** group is available if an edge is filleted by the method **With Circle Arc** (see Table 2.3.10 on p. 190).

2.3.8.2.4. Fillet with a maintained edge or surface

If the fillet surface intersects with adjacent faces, there are two ways of performing the operation:

- ▼ with a maintained edge;
- ▼ with a maintained surface.

To select the first variant, enable the **Maintain Edge** option on the **Parameters** tab of the Property Bar. In this case, the shape of neighboring face edges will be saved (Fig.2.3.45, b).

If this option is off, fillet shall be created with surface saving. The shape of neighboring face edges may change (Fig.2.3.45, c).

Fig. 2.3.45. Fillet: a) initial features, b) fillet with saving the edge, c) fillet without saving the edge

Sometimes the relative disposition of rounding surfaces and specified radius of the fillet do not allow saving the edge. If, in such a case, the **Save Edge** option is enabled, then any attempt to create a fillet shall produce a system error message.

To avoid such an error, enable the **Auto Determination** option. In this case, the system will create a “composite” fillet. Wherever possible, edges of neighboring faces shall be saved. Where saving of edges is impossible, surfaces of neighboring faces shall be saved.

If auto determination is on, the **Save Edge** option is unavailable and its state is ignored when constructing a fillet.

2.3.8.2.5. Stopping filleting

You can stop filleting if it involves a single edge (or a chain of edges). You can specify one or two stopping points on an open edge (chain), it is mandatory to specify two points for a closed edge.

Fig. 2.3.46. Stopping filleting

To stop filleting at a certain point on the edge activate the **Stop Filleting** tab on the Properties panel and enable the **Stopping** option.

The tab has the **Stopping points** panel. The panel contains a table for setting stopping point parameters: point numbers, distances to them from the starting point of the edge (or chain) being filleted, information about associative links with the object.

Set a fillet stopping point(s). To do so, you can use the following methods:

- ▼ specify an arbitrary point on the edge,
- ▼ specify a vertex that belongs to the chain of edges being filleted,
- ▼ specify an object for associative connection:

- ▼ point object belonging to the edge being filleted,
- ▼ 2D object intersecting the edge being filleted (the stopping point in this case is the point of intersection of the edge with the said object).

The set stopping point is marked in the model screen by a number and an arrow. The arrow shows the direction of filleting: that part of the edge where the arrow points at will remain unchanged, while the rest of it will be filleted.

In the table on the Properties bar the stopping points are numbered in the order they are specified. If a point is specified arbitrarily, the values in the **%** or **Length** column can be edited. As you change the values, the point will move on the model screen.

If there is an association link between the stopping point and the object, the **Object link** column will have a check mark, and it is impossible to change values in the **%** and **Length** columns. When you highlight the row in the table that corresponds to the point linked with the object, a switch and a field named **Object** appear on the Properties bar. The switch will have a check mark, and the field—name of the object linked with the point. To cancel the link, you need to either click in the cell of the **Object link** column, or the **Object** switch. Note that to restore the link you need to select the object again.

You can change the fillet truncation direction to the opposite by clicking the **Change direction** button above the list.

If the 2D object using which the stopping point is determined intersects the edge being filleted in several points, the **Next** and **Previous** buttons become available. They are used to select the appropriate point.

You can delete the table row and, consequently, a point in the part preview window. To do this, click the  button placed over the list.

By default, the filleting is truncated in the stopping point by an intersecting plane perpendicular to the edge (Fig. 2.3.46). If the stopping point is set as the point of intersection of the edge with a 2D object, the fillet can be trimmed by that object's plane. To do so, select the row that corresponds to that point and enable the **Object trimming** option.

2.3.8.3. Body transformation into shell

At any stage of work, a body (or several bodies) can be transformed into a thin wall shell.

When creating a shell, the entire part body is excluded from calculations while a layer of material is added on its sides creating a shell.

To create a shell, you need to exclude one or several faces from adding material. These faces will become holes (or a hole) in the resulting shell.

When working with a body made up of multiple pieces, you can exclude faces of some of them. These pieces are transformed into shells with holes while the rest of them are transformed into closed shells.

To create a thin wall shell, apply the  command.

Select direction of material adding— **Outward** or **Inward** relative to the part surface. To do this, activate the applicable switch in **Thin Wall Type** group.

If material is added outwards, input shell thickness into the **Wall Thickness 1** field; if inwards— into the **Wall Thickness 2** field.

Select body faces that should not be involved in shell creation. The number of these faces is displayed in the **Number of Removed Faces** reference field.

To exclude some face from being selected, click it in the part window again. The face will be deselected and not removed when creating the shell.

To deselect all faces, click the **Reselect** button on the Special Control panel.

Fig. 2.3.47. Creation of a thin wall shell: a) initial part, removed faces are selected, b) result of thin wall shell creation

Once execution of the operation is confirmed, the Model Window will display image of a thin wall shell and the Tree will display its respective icon.

Working with the resulting shell will be the same, i.e., adding and subtracting bodies, creating chamfers, fillets and holes.

2.3.8.4. Rib

Before constructing a rib in the model, you need to create a sketch defining the shape of the rib. The rib is constructed from the sketch's line to the body. As a result, a thin wall is formed limited by the sketch's line on the one side, and by the body's faces on other sides.

2.3.8.4.1. Rib Sketch Requirements

- ▼ Sketch objects should comprise one contour.
- ▼ The contour must be open.
- ▼ Tangents to a contour in its end points must intersect the body.
- ▼ The contour does not have to reach the body. The system shall continue the contour up to the intersection with the nearest face. Curvilinear contours are extended tangent to their end points.

2.3.8.4.2. Generating a Rib

To create a rib, call the **Rib** command.

The **Rib** command is accessible if one sketch (rib sketch) is selected.

If a part consists of multiple bodies, then, to create a rib, you need to specify the one to which the created edge shall be attached. You can attach edges both to the bodies built within the model itself and ones built in the components. Note that faces limiting an edge should belong to the same body.

To select a body, select any face, vertex or edge of that body in the model window or select in the Design Tree an object belonging to that body of any of the following types:

- ▼ First shape-generating feature
- ▼ Shape-generating boss feature
- ▼ A boss sheet body
- ▼ glued mirror copy of a body
- ▼ Boolean operation.

The selected object will be highlighted.

It is most convenient to select a face (or one of the faces) to which the rib will be connected directly in the model window.

If you accidentally made a mistake when selecting body points, click the **Reselect** button on Special control panel. Highlighting will be cleared off the previously selected object and a new body may be selected.

Using control features of Properties toolbar, set the rib parameters:

- ▼ position— on the **Parameters** tab (see Section 2.3.8.4.3),
- ▼ face draft—on the **Parameters** tab (see Section 2.3.8.4.4),
- ▼ thickness— on **Thickness** tab; it is specified in a similar way as when setting up thin wall parameters (see Section 2.3.2.7 on p. 161), with the only exception that: you can not cancel the construction of thin wall by clicking **No** option.

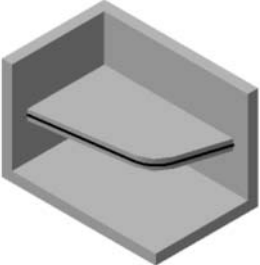

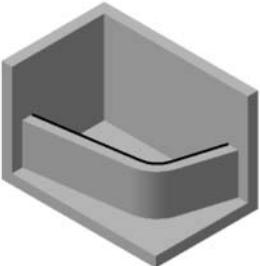

Once execution of operation is confirmed, a rib will appear in part preview window, and its respective icon will appear in the Tree.

2.3.8.4.3. Position of Rib

Rib may be perpendicular or parallel to the sketch plane. To select a construction option, activate the applicable switch in **Position** group (see Table 2.3.13).

Tab. 2.3.13. Possible rib positions

	Value of Position option	Rib position and shape	Construction result
	In the Plane of sketch	Rib is parallel to the sketch plane. A sketch constrains the rib along perimeter.	
	Orthogonal to Sketch	Rib is perpendicular to the edge sketch plane. Rib surface is created by sketch extrusion.	

If the part body is on one side from the sketch, the system shall automatically determine the direction of the edge extrusion (to the part side). This is the **Forward Direction**. To change direction of rib construction, activate the **Reverse Direction** switch in **Direction** group. Direction of rib construction is shown on a ghost in the model window as an arrow.

2.3.8.4.4. Draft of Rib Faces

If the feature faces are to have a draft, enter its value into **Draft Angle** field. Side faces of the rib shall be sloped outwards under specified angle.

If the rib sketch consists of several segments (straight lines), you can select a segment defining the draft direction. To do this, use the **Next** button. Upon clicking it, one of the sketch segments is highlighted. Click the button until the required segment is highlighted. The narrow side face of the rib corresponding to that segment will be accepted as the draft base. The side faces of the rib will be drafted with respect to it by the specified angle (Fig.2.3.48).

Selecting a segment to provide the draft direction makes sense only if rib construction is done in the sketch plane (when **In the sketch plane** switch is on).

Fig. 2.3.48. Rib with a slope. Rib sketch consists of three segments. Segment defining draft direction is highlighted.

2.3.8.5. Face Draft

To apply a slope to flat faces perpendicular to the base or cylindrical faces whose constituents are perpendicular to the base, call the **Draft** command.

To construct a draft, you should specify its base and sloping faces.

Draft base is a flat face of the part whose shape, dimensions and the inclination angle do not change after performing the **Draft** command.

Sloping faces are faces whose inclination angle with respect to the base will change as a result of performing the **Draft** command.

To select a base, activate the **Base** switch and select the required face in the part preview window.

To select faces to draft, activate the **Faces** switch and select the desired faces in the Part window.

There is always only one base. There can be several sloped faces.

Sloping faces should merge with the base. They may be not merged with each other.

Select direction of sloping faces — **Inward** or **Outward** — by activating the applicable switch in the **Draft** group. If faces slope inwards, the feature section is decreasing, if outwards— increasing.

Sometimes, different faces can be selected as the base. In this case, the result of the command will depend on the relative position of the base and the sloping face (Fig.2.3.49).

Fig. 2.3.49. Draft: a) initial part and sloping face, b) and c) result of creating a draft depending on base

Enter the inclination angle value in the **Angle** field.

If the **Draft** command is applied to a face already drafted with respect to the base by some angle, that angle will be discarded, i.e., the result will be the same as if the command was applied to a face perpendicular to the base.

Once execution of operation is confirmed, the selected faces shall obtain a slope, and a matching icon shall appear in Design Tree.

Do not slope faces individually. If possible, select the most number of faces to be drafted by the same angle with respect to the same base using the **Draft** command. In this case, calculations will be run faster upon model rebuilding.

The command is not performed if the system finds that the faces rebuilt according to the specified slope parameters do not form a body.

If you need to fillet one or several edges bounding the sloped face, do this after applying the slope on the face.

Using the **Draft** command is most efficient at final stages of designing diecast parts, when certain faces need to be drafted in order to ease casting separation from the form.

Generally speaking, sloping to side faces of extrusion feature can be done by editing parameters of this feature. However, this method differs significantly from execution of sloping operation:

- ▼ The **Draft** command lets bending separate faces, while all side faces are bending at an extrusion with a draft.
- ▼ The **Draft** command executing does not change position of features subjected to sloping faces, and editing the extrusion feature with sloping faces “bends” the objects subjected to these faces.

2.3.8.6. Trimming a part of the model

At any stage of part modelling, you can delete a component of its body (bodies). The border of section can be a surface of a free form or a cylindrical surface created by extrusion of an arbitrary sketch.

Note that the plane or surface used for cutting off can belong either to the model itself, or any of its components, while a sketch must belong directly to the model.

Generally speaking, these actions can be performed using the **Cut off by Extrusion** command. However, this will require setting a greater number of parameters and, in some cases, a more complex sketch than it is necessary for cutting off part of the model.

To cut a model component off by an intersecting plane or an extrusion surface, special commands are provided. They are located in the **Operations— Section** menu. Shortcuts are placed in one group on **Edit Part** toolbar.

Position and form of a cutting surface may be such that the section operation may result in a body made up of multiple pieces (see Section 2.3.11 on p. 224).

2.3.8.6.1. Section by Surface

To delete a model component located on one side of the intersecting surface, apply the **Section by Surface** command.

The following objects can be used as a base point:

- ▼ Base and auxiliary surfaces
- ▼ Surfaces imported and created in a part
- ▼ faces.

Flat surface can be lengthened in any direction, which is why it is not necessary to place it to intercept the whole item. Lengthening of a non-flat surface is not allowed, therefore the correct cut of an item part is only possible when it intercepts the whole item body.

If, before calling the command, a surface intersecting with the model was selected, then the surface name will appear in the **Section Surface** field on the Properties toolbar.

If no surface was selected before calling the command, select one.

You can delete a component of a part on any side from the surface of section. To select direction, activate the applicable switch in the **Direction of Cutting**— or group. Direction of cutting is shown on a ghost in the part preview window as an arrow.

Fig. 2.3.50. Cutting a component of the part by plane:
 a) initial state of the part (cutting plane is denoted relatively),
 b) result of cutting operation

If you are working with a multibody part, setting of an operation application area may be necessary as well as parameter setup. For this, the **Operation Result** tab of the Properties panel is used. Detailed information on operation application area and methods of its specification is provided in Section 2.3.10.3 on p. 219.

Once execution of operation is confirmed, the model shall be cut off, and a corresponding icon shall appear in the Design Tree.

2.3.8.6.2. Section by Sketch

To delete a part component lying to one side of an extrusion surface intersecting this part, use the **Section by Sketch** command.

Cutting surface is created by moving the sketch in the direction perpendicular to its plane.

Before calling the command, select the sketch that contains the profile of the ruled surface.

Section Surface Sketch Requirements

- ▼ Sketch objects should comprise one contour.
- ▼ The contour must be open.
- ▼ The contour should intersect the part projection on the sketch plane.

Section

Call the **Section by Sketch** command.

The name of the sketch that will be used for cutting off appears in the **Section Profile** field on the Properties toolbar.

You can delete a component of a part lying to any side from the extrusion surface. To select direction, activate the applicable switch in the **Direction of Cutting**— or — group. Direction of cutting is shown on a ghost in the part preview window as an arrow.

Fig. 2.3.51. Cutting a part component by sketch:
 a) initial state of the part, the sketch of the surface to be cut off is shown,
 b) result of cutting operation

If you are working with a multibody part, setting of an operation application area may be necessary as well as parameter setup. For this, the **Operation Result** tab of the Properties panel is used. Detailed information on operation application area and methods of its specification is provided in Section 2.3.10.3 on p. 219.

Once execution of operation is confirmed, the model shall be cut off, and a corresponding icon shall appear in the Design Tree.

2.3.8.7. Scaling of bodies and surfaces

Scaling allows changing body or surface dimensions in three directions according to the set factor. The result body or surface can be used with no restrictions in any future operations, including the scaling operation.

The **Scaling** command is available if there is at least one body or surface in the model. Scaling operation is also applicable to component bodies and surfaces.

To perform a scaling operation, click the **Scaling** button on the Edit Model toolbar or select its name from the **Operations** menu.

Select the body or surface to be scaled in the Design Tree or Window.

The body icons and names are shown on the Tree if the model structure is enabled (see Section 2.1.2.2 on p. 106).

If a model contains one body or surface, this body or surface is selected automatically.

The selected object is highlighted in the Design Tree and in the Model window. An outline box is also displayed in the Model window; you can visually estimate scaling by its further change.

The **Body or Surface** field on the Property bar displays the object name.

You can change the dimensions of one body or one surface in a single **Scaling** command call.

Input or select the scaling factor in the counter.

The scale factor can be also set using a handle (see Section 2.1.4.2.2 on p. 138).

In the Design Tree or in the Model window, select the scaling center: a vertex or a point in the space specified as a fixed one. Upon completing this command, the distance between this point and the center of gravity of the scalable object will change proportionally to the scale factor and in the direction of the line segment connecting these points.

By default, the origin of the current coordinate system is the centerpoint.

The point is highlighted in the model and its name is displayed in the **Center Mark** field.

To change the scaling centerpoint, select a new point in the Model window.

You can create a point by clicking the **Point Drawing** button on the Special Control Panel (for details see Section 2.5.2.11 on p. 346).

During the process of entering the scaling parameters, the outline box shall change its dimensions and position relative to the scaling centerpoint and proportionate to the specified factor.

To select other objects for this operation, click button **Select other** on the Advanced Control Panel. The current object selections will be cancelled allowing you to specify new objects.

Object name, color and visual properties of its surface can be specified on the **Properties** tab of the Property Bar.

When you have set the operation parameters, click **Create Object** button on the Special Control panel.

The scaled body or surface shall appear in the Model window and the respective icon shall appear in the Design Tree.

Please note that only bodies themselves or surfaces can be subjected to scaling. Their source and derivative objects - sketches, thread notations, symbols, etc.— remain unchanged.

While further working with the model created using the **Scaling** command, the following data shall be accounted.

- ▼ A scaled **sheet body** loses its respective properties specific for this body type.
- ▼ When creating a **object arrays**, previous scaling operations on the object will be ignored. Sizes and in-model positions of the array instances are those as if such arrays were created prior to scaling.
- ▼ The **mates** applied to assembly objects ignore any subsequent changes in object size and position as a result of the scaling. To correct mates, edit them by re-specifying mated objects.

2.3.8.8. Body or surface position change

Position change operation allows to move body or surface to an arbitrary model point and to rotate it at arbitrary angle.

The result of the operation is a **new object**— body or surface. Objects derived from the initial (“old”) body or surface remain connected to this body or surface. New body or surface can be used with no restrictions in any future operations, including the position change operation.

Depending on the setting made during operation execution, an initial object is deleted from the model or remain in it. If this object was used in mates, the mates are marked as faulty in case this object is deleted. To correct mates, edit them by re-specifying mated objects.

Body or surface position change is made in the coordinate system defined by a user. It becomes coordinate system for change position operation (for more on object coordinate system see Section 2.8.3.4.1 on p. 598).

The Body or Surface Position Change command is available if there is at least one body or surface in the model. You can change the position of one body or one surface in a single command call. Note that change position operation is applicable to bodies and surfaces created in the model itself only (not in any of its components).

To change a body or surface position perform the following actions.

1. Start the body or surface position change operation To do this, click the **Change Position** button on the model editing toolbar or call the **Operation — Change Position** command.
2. Specify the object (body or surface), whose position should be changed, in the Design Tree or in the model window.

The body icons and names are shown on the Tree if the model structure is enabled (see Section 2.1.2.2 on p. 106).

If a model contains one body or surface, this body or surface is selected automatically.

A selected object and coordinate system (by default— the current) in which position change will be performed are highlighted in the Design Tree and in the model window.

A special element is displayed in the model window to control the object's shift and rotation— **a ghost of the coordinate system**. Object position changing is performed by changing position of this ghost. Mutual position of the object and of the coordinate system's ghost does not change. At first, the ghost coincides with the selected coordinate system. You can move ghost along coordinate system axes, along its own axes and also rotate around its own axes.

3. If you need to use another coordinate system, specify it in the Design Tree.

If there is no suitable coordinate system in the model, create new local coordinate system. To do this, click the **LCS Construction** button on the Special Control Panel. LCS creation process will be started (see Section 2.8.3.5 on p. 601). Specify LCS position and click the **Create Object** button. The system will resume the changing the object position operation process, created LCS will appear in the Design Tree and will be automatically selected as coordinate system in which position changing is performed.

4. Specify whether to delete the initial body or surface. To do this, activate the desired switch in the **Mode** group:

- ▼ **Delete source objects** – the number of bodies (surfaces) in the model does not change, the source body (surface) is not displayed in the model window, but displayed as a subordinate object of the *Change Position* operation in the Design Tree.

- ▼ **Keep source objects** – the number of bodies (surfaces) in the model is increased by one, the initial body (surface) is displayed in the window and in the Design Tree at its previous position.

5. To specify position and orientation of coordinate system ghost, activate the **Parameters** tab of the Properties bar. Two methods of setting position and orientation are available. They are

similar to those used when creating a local coordinate system. To choose a method, expand the **Method** list and select the required row:

- ▼ **Respective to CS**— respective to the specified coordinate system (See Section 2.8.3.6.1 on p. 603),
- ▼ **By Object**— by object the properties of which allow uniquely defining coordinate system ghost position and orientation (see Section 2.8.3.6.2 on p. 605).

Shift and/or rotation of coordinate system ghost is shown on the object ghost: it is positioned in accordance with the new position of the coordinate system.

If you need to position an object with respect to a coordinate system (CS1, for example) in the same way it is positioned with respect to another coordinate system (CS2), specify CS2 as the coordinate system to be used for changing position while SC1 should be specified as an object which defines position and orientation of the coordinate system's ghost.

6. If necessary, change the direction and color of new body or surface. For that, use control elements on the **Properties** tab of the Property bar.

7. Click the **Create Object** button on the Special Control Panel to complete the operation.

Body or surface will change its position in the model window; an icon will appear in the Design Tree indicating the position change operation.

2.3.9. Round hole

Creation of a round hole is one of the body editing operations. KOMPAS-3D supports creating round holes of the following types:

- ▼ **Simple hole,**
- ▼ **Countersink hole,**
- ▼ **Counterbore hole,**
- ▼ **Hole with countersink and counterbore,**
- ▼ **Conical hole.**

Construction of round holes is described in Section 2.3.9.1 on p. 208.

Besides that, you can create a round hole by a sketch profile using the library of holes. For this purpose, use the **Hole from Library** command (see Section 2.3.9.2 on p. 215).

The group of commands for creating round holes of different types and the **Hole from Library** command can be found in the **Operations – Hole** menu.

Their shortcut buttons are located on the model editing toolbar (Fig. 2.3.52).

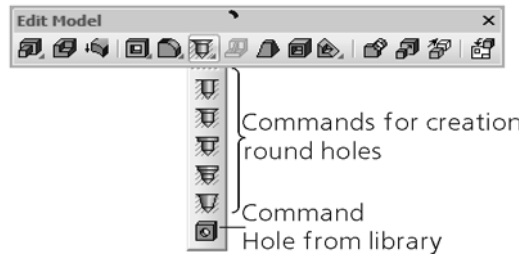

Fig. 2.3.52. Buttons for round hole creation commands and the **Hole from Library** command

2.3.9.1. Round hole: simple, with countersink/counterbore, conical

In order to create a certain type of hole, call the respective command:

Simple hole;

Hole with Countersink;

Hole with Counterbore;

Hole with Countersink and Counterbore;

Conical hole.

Once the command is called, control elements for setting the hole parameters appear in the Property Bar (Fig. 2.3.53). Some parameters are set for all types of holes, while other parameters depend on the hole's type.

During the construction process, you can change the hole's type by selecting the required line in the **Hole Type** list. Choosing a hole type from the list has the same effect as calling the command for creation of the respective round hole.

Sketch of the selected hole's type is displayed in the preview window on the **Hole Parameters** bar.

To create the round hole, complete the following steps.

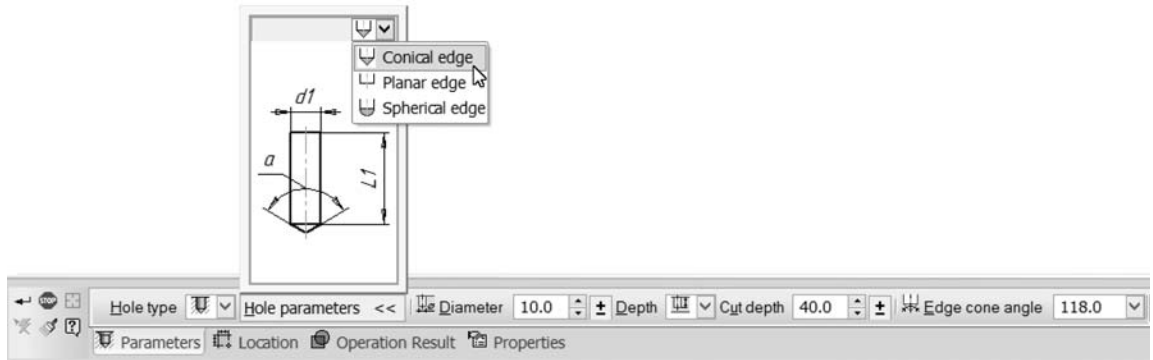

Fig. 2.3.53. Property bar during a simple hole construction

1. After calling the command, specify the surface on which the hole will be located. The ghost of the hole with the specified parameters will appear in the Model window. The hole's anchor point is the point specified for the hole on the selected surface.

During the construction process, you can choose another surface for the hole placement.

2. Enter the hole diameter value in the **Diameter** field.
3. Specify the hole's depth (see Section 2.3.9.1.1 on p. 210).
4. Specify parameters depending on the hole's type:
 - ▼ for a hole with countersink and/or counterbore (see Section 2.3.9.1.2 on p. 211),
 - ▼ for a conical hole (see Section 2.3.9.1.3).
5. If necessary, you can also:
 - ▼ Creating a threaded hole (see Section 2.3.9.1.4 on p. 212).
 - ▼ Specify the hole's edge form (see Section 2.3.9.1.5 on p. 213).
 - ▼ Creating hole axis. For that, enable the **Axis** option.
 - ▼ Specify the hole's location parameters (see Section 2.3.9.1.6 on p. 214):
 - ▼ position of the hole's anchor point,
 - ▼ slope and axis turn,
 - ▼ direction of the construction,
 - ▼ cutting out part of the body above the hole,
 - ▼ Creating a hole using a template (see Section 2.3.9.1.7 on p. 215).

Diameter, depth, and position of the hole on the surface can be changed using handles.

If you are working with a multi-body part, beside parameter setup, setting of operation application area can be necessary. For this, the **Operation Result** tab of the Properties panel is used. Detailed information on operation application area and methods of its specification is

provided in Section 2.3.10.3 on p. 219.

6. Upon completion of the hole parameterization click the **Create Object** button on Special Control Panel.

The model with the hole on the specified surface will be displayed in the window, and an icon corresponding to the selected type of hole will appear on the Design Tree. If the hole was created with an axis and/or thread, an additional axis and/or thread icon will appear on the Design Tree as a subordinate object of the hole. Next to its symbolic depiction, thread specification is given (for non-standard thread, a *Symbolic thread depiction* message is used).

2.3.9.1.1. Specifying the hole's depth

For all types of round hole, depth is specified starting from the hole's anchor point to the center of the edge of the hole's straight round cylinder.

The hole's depth can be specified using different methods.

Choose the method of specifying the hole's depth from the **Depth** list (see Table 2.3.14).

Depth of the hole having a conical or spherical edge is increased by the edge's height. For detailed description of the edge's form selection, refer to Section 2.3.9.1.5 on p. 213.

Tab. 2.3.14. Method of specifying the hole's depth

	Value of the Depth option	Building rules
	By Length	The hole's depth is defined by the specified distance. The Depth of cut field is available. Enter the distance's value in that field.
	Through All	The hole's depth is defined by distance between the specified surface and the intersection point of the hole's axis with the plane perpendicular to the axis and going through the point of the model's outline box which is the outermost from the anchor point.
	To Vertex	The hole's depth is defined by the absolute value of the distance between the hole's anchor point and the projection of the point object to the hole's axis. Specify the point object in the Model window. The name of the selected object is displayed in the Vertex field beside the switch. To change the point object, enable the Vertex switch and reselect the object.
	Up to Surface	Depth of the hole is defined automatically by position of a face or a plane specified by user. The hole is cut up to the selected surface. The endface of the hole has the surface form. Specify the surface in the model window that limits the hole's depth. The name of the selected object is displayed in the Surface field beside the switch. To change the object, enable the Surface switch and reselect the object.

2.3.9.1.2. Parameters of the hole with countersink and/or counterbore

For a hole with countersink and/or counterbore, further to parameters that are general to all types, countersink and/or counterbore setup parameters are also specified. All parameters are displayed in the hole's sketch in the preview window on the **Hole's Parameters** bar (see Fig. 2.3.53 on p. 209).

- ▼ For a hole with countersink, choose the countersink parameters' specification method from the **Method** list (see Table 2.3.15) and specify the respective values.

Tab. 2.3.15. Method of setting countersink parameters

	Value of option	Building rules
	Method	
	By diameter and angle	The countersink surface is defined by its diameter and cone angle. Enter the countersink diameter value in the Countersink diameter field. Specify or choose the value of the countersink cone angle from the Countersink angle list.
	By depth and angle	The countersink surface is defined by its depth and cone angle. Enter the countersink depth value in the Countersink depth field. Specify or choose the value of the countersink cone angle from the Countersink angle list.
	By diameter and depth	The countersink surface is defined by its depth. Enter the diameter value in the Countersink diameter field. Enter the depth value in the Countersink depth field.

- ▼ For a hole with counterbore:
 - ▼ specify the counterbore diameter in the **Counterbore diameter** field,
 - ▼ specify the counterbore depth in the **Counterbore depth** field,
- ▼ For a hole with countersink and counterbore:
 - ▼ specify total diameter of countersink/counterbore in the **Countersink/counterbore diameter** field,
 - ▼ specify the counterbore depth in the **Counterbore depth** field,
 - ▼ enter the counterbore cone angle in the **Counterbore angle** field.

All changes of dimensions will be reflected in the hole's ghost.

2.3.9.1.3. Conical hole parameters

For a conical hole, apart from parameters that are general for all types, conical form parameters should be set up. There are two methods to set the parameters. Using each of the methods, conical form of the hole is achieved by increasing the diameter of the cone's upper base (the diameter going through the anchor point of the hole). The diameter of the lower base of the cone is equal to the value specified in the **Diameter** field. All parameters of the conical hole are displayed in the hole's sketch in the preview window on the **Hole's Parameters** bar (see Fig. 2.3.53 on p. 209).

Once the cone's lower base diameter is set together with the hole's depth, choose the method of setting parameters of the conical hole from the **Method** list and specify their values (see Table 2.3.16).

Tab. 2.3.16. Method of setting parameters of a conical hole

	Value of option	Building rules
	Method	
	By diameter of the cone's upper base	The hole's surface is defined by the diameter of the upper base of the cone. Specify the diameter of the cone's upper base in the Base Diameter field.
	By cone's angle	The hole's surface is defined by the cone's angle. Specify the cone's angle in the Cone's angle field.

2.3.9.1.4. Creating a threaded hole

Round hole of any type can be threaded. In this case when creating the hole a symbolic depiction of thread is formed, too. Hole diameter is defined by thread parameters — nominal diameter and step. The thread can be both standard and non-standard.

To create a threaded hole take these steps.

1. Open the **Hole's Parameters** bar (see Fig. 2.3.53 on p. 209).
2. Click the **Threaded hole** button.
On the Properties Bar controls will appear for setting thread parameters.
3. Select the name of the thread from the **Thread standard** list. The list contains the names of standard threads and a **Non-standard thread** item.
4. Set thread parameters.

Thread parameters can be set using the following methods.

▼ Method 1

- ▼ For non-standard thread type or select from the list the value of nominal thread diameter in the **Thread diameter** field, and pitch—in the **Pitch** field.
- ▼ For standard thread, pitch value is set automatically after specifying the diameter. If the **Pitch** list contains several pitch values, you can change the automatically set value.

▼ Method 2 (for standard thread).

- ▼ Click the **Select standard thread parameters** button. A **Select standard thread parameters** dialog box with a table will appear on the screen.
The **Standard** list on the dialog box displays the name of selected thread standard. If required, you can select a different thread standard on the list.
The column of the table contain the values of nominal thread diameter, pitch and other thread parameters applicable to the selected standard.
- ▼ Highlight the appropriate row in the table and click **OK**. On the Properties panel, the **Thread diameter** field will show the value of nominal thread diameter, and the **Pitch** field—value pitch from the highlighted row.

5. Select the method of setting thread length in the **Thread length** group of switches.

The following methods are available.

- ▼ **Specified depth:** thread length is defined by the specified distance. Enter thread length value in the **Thread Length** field.

The object from which the distance is calculated is (Fig. 2.3.54):

- ▼ for countersink holes — lowest point of the countersink surface,
- ▼ for all other holes — hole location surface.

Fig. 2.3.54. Initial thread border for different types of holes

- ▼ **Total depth:** thread length is determined automatically using the depth of the hole.

If required, you can change the automatically calculated end limit of the thread. To do so, activate the **End limit** switch, then specify on the Design Tree the surface, facet, or plane for which you want to plot the hole.

Symbolic thread depiction appears on the hole ghost.

In a conical hole, standard thread can be plotted to a specified depth only. Maximum depth depends on the hole dimensions and is set by the standard.

Standard thread tables

Standard thread parameter tables are found in the folder whose path is set in the system variable *Thread* (see Section 9.5.4 on p. 1886) of the system KOMPAS-3D. By default, it is subfolder *...Sys\Thread* in the main system folder.

You can manage the list of standard thread tables and their connection using the **Thread parameters** (see Section 9.1.11.11 on p. 1736). The delivery package includes KOMPAS-3D metrical, pipe, buttress and trapezoidal thread tables.

The said tables contain standard thread parameters. Use them as templates for creating your own thread tables.

When a symbolic depiction of thread is created in the model using the tables, no link between the model and the thread table file is formed.

2.3.9.15. Specifying the hole's edge form

When creating a hole, you can define the form of its bottom.

Open the **Hole's Parameters** bar (see Fig. 2.3.53 on p. 209). Open the **Edge Form** list and choose the required variant.

▼ **Conical edge,**

▼ **Flat edge,**

▼ **Spherical edge.**

For a conical edge, specify the cone's angle value in the **Edge's cone angle** field.

2.3.9.1.6. Hole positioning on surface

There are several parameters of positioning a hole on surface. To set the parameters, activate the **Positioning** tab. The Property Bar will display controls for specifying the hole's position on surface, orientation of its angle and direction of its construction.

Position on surface

In the model window, specify the surface for positioning the hole making sure the **Surface** button is enabled. The name of the chosen object will be displayed in the **Placement Surface** field. Positioning of the hole's anchor point on the selected surface is identical to creation of a point on surface (see Section 2.5.2.6 on p. 339).

Direction of the hole's axis

By default, the hole's axis is perpendicular to the placement surface. You can change the direction of the hole's axis. To do this, turn off the option **Perpendicular to surface**.

There are several methods to change the direction of the hole's axis:

▼ Inclination and rotation of the hole's axis as compared to its default position.

In order to incline the hole's axis, specify inclination angle in the **Inclination angle** field.

In order to rotate the hole's axis, specify the rotation angle in the **Rotation angle** field.

▼ Specifying the guide object.

Enable the **Axis direction** switch and specify the guide object in the window or in the Design Tree. The guide object can be an existing straight-line, flat object or a rotation surface (except for sphere). The straight-line object sets direction parallel to itself; the flat object sets direction perpendicular to its plane, while the rotation surface sets direction which is parallel to its axis. The list of straight and flat objects is presented in Table 2.1.7 on p. 131.

▼ Creation of a guide vector

Direction of the hole's axis will coincide with the vector's direction.

In order to create the vector, use the **Vector Construction** button on the Special Control Panel. For more information about construction of the guide vector, see Section 2.8.5 on p. 613.

Building Direction

Direction of the hole's construction can be specified using switches of the **Direction of Construction** group. By default, the hole is built in the inside direction with respect to the surface

on which it is located. This direction is **Straight**. Activate the **Reverse Direction** switch to change the direction of construction.

Deletion of the body's part above the hole ("canopy" processing)

In some cases, the body, in which a hole is created, forms a "canopy" above it. The "canopy" can be removed by lengthening the hole's surface in the direction which is opposite to the hole's construction direction. For this purpose, the **Process "canopy"** option is designed (Fig. 2.3.55).

Fig. 2.3.55. Creation of a hole with countersink: a) the **Process canopy** option is disabled; a) the **Process canopy** option is enabled

Note that if no new face is formed immediately above the hole as a result of the hole construction, the body's material will not be removed, since in this case it is considered that there is no "canopy" (Fig. 2.3.56).

Fig. 2.3.56. Hole's position in the model: a) no "canopy", b) with "canopy"

2.3.9.1.7. Creating a hole using a template

To plot a hole you can use the parameters of a template hole.

On the Special Control Panel, click **Hole by Template** (the **Parameters** tab must be active on the Properties panel). Specify the hole to copy the parameters of in the model or on the Design Tree. The hole being created will have the same parameters, as the template hole. Edit the parameters, if required. If the position of the hole is not set yet, set it now.

2.3.9.2. Hole from Library

In order to create a round hole using the library of holes, select the flat object on which it should be positioned (the list of flat objects is presented in Table 2.1.7 on p. 131). Then, call the **Hole from Library** command.

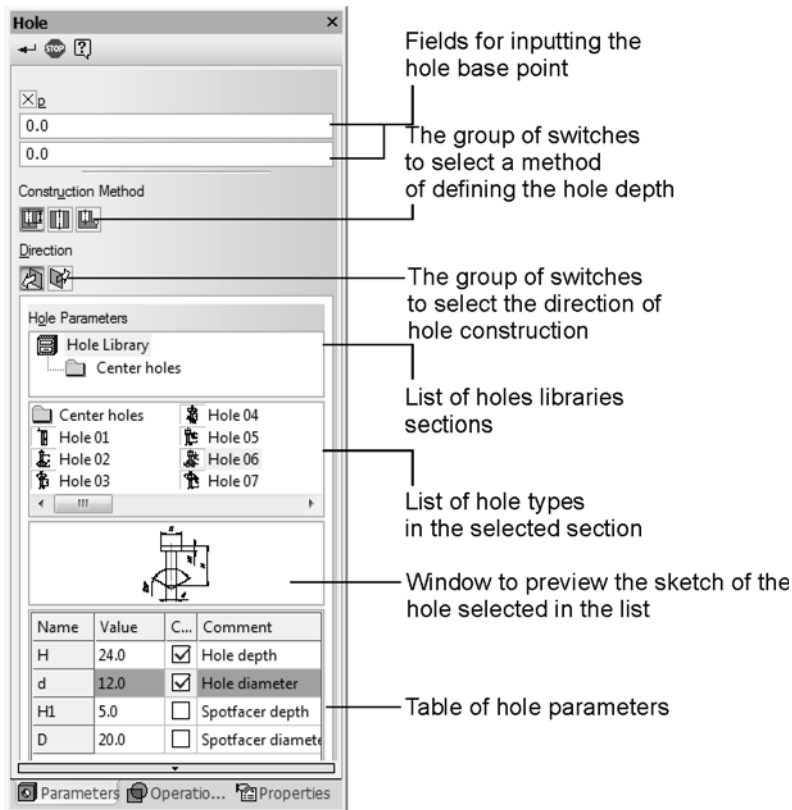

Fig. 2.3.57. Hole properties panel

Upon calling the command, control features to select the hole profile and to enter its geometric sizes shall appear (Fig.2.3.57) on Properties toolbar.

Select the type (shape) of the hole from the drop-down menu. The selected profile sketch of the hole type is displayed in the preview window below the list of types.

This sketch is parametric. The hole parameters are controlled by values of applicable sizes in the sketch. List of variable parameters of the hole is displayed below the preview window.

To change any of the hole parameters, enter the required value into corresponding field of parameter table.

Not all dimension values can be modified arbitrarily. For example, the thread diameter cannot be made greater than the nominal diameter of the hole. If you need to increase the hole diameter, first change the nominal diameter, and then the thread diameter.

Enter the required values of all hole parameters.

If the overall depth **H** parameter is present among parameters of the selected hole, the switch keys of the **Method of Construction** group become available. They allow to indicate which method the hole depth is defined with.

If the **On Depth** switch is activated, the depth of the hole shall be equal to the specified value in the list of parameters. If the **To Vertex** or **Through All** switch is activated, the H parameter disappears and the depth of the hole is defined automatically. The concept of automatic depth determination is the same as the one for cutting extrusion feature. If **To Vertex** switch is disabled, you should select this vertex.

The hole ghost with specified parameters will appear in the Part window. By default, the snap point of the hole (it is marked in red color in the sketch) is located in the origin of the local coordinate system of the face on which this hole is created.

To fix the hole in the required place of the face, unfix the fields for input of the snap point coordinates. For this purpose, click the m field. The cross in this field will change to a checkmark. Indicate the position of the hole with mouse or enter coordinates of the hole center.

If you are working with a multi-body part, beside parameter setup, setting of operation application area can be necessary. For this, the **Operation Result** tab of the Properties panel is used. Detailed information on operation application area and methods of its specification is provided in Section 2.3.10.3 on p. 219.

Upon specifying all the parameters of the hole, click the **Create object** button on Advanced Control Panel.

The part with the hole on the specified face shall be displayed in the window, and the hole icon shall appear in the Design Tree.

If the hole fully intersects the body, the operation shall result in a body made up of multiple pieces (see Section 2.3.11 on p. 224).

You may create your own library of holes or add holes to the system library (see Section 12.1.4.3 on p. 2045).

2.3.10. Application area of operation

2.3.10.1. General Information

Operation application area is a set of objects affected by the result of the operation. The application area of the operation can comprise the bodies or components the model contains, or both.

When you add model material (e.g. when you paste shape-generating features), the application area defines the bodies to be combined with the feature being created (edited); and when you delete model material (e.g. when you cut shape-generating features out), it defines the bodies which material will be deleted as a result of the operation.

Let's assume the model contains three bodies. An extrusion operation sketch is created on the top face of body 1 - a circle (Fig. 2.3.58, a). The method of defining the extrusion depth is **Through All**. Any of those bodies, and in any combination, can be included in the operation application area. Let us suppose that the application area consists of the bodies 1 and 3.

Fig. 2.3.58. Extrusion operation application area:
 a) initial state of part and sketch of operation,
 b) result of cutting, c) result of editing a boss

- ▼ If the extrusion feature is to be cut out, the operation will produce a hole only in the bodies 1 and 3 (Fig. 2.3.58, b). Even though the extrusion feature goes through the body 2, it will stay unaffected since it is not included in the operation application area.
- ▼ If the extrusion feature is to be pasted, then a new body consisting of the bodies 1, 3 and the extrusion feature will appear (Fig. 2.3.58, c). Even though the extrusion feature goes through the body 2, it will stay alone, since it is not included in the extrusion operation application area.

2.3.10.2. General procedure for setting operation application area

1. Selection of the application area type. To do this, the switch **Application Area** is used. It appears on the page **Parameters** of the Properties bar during execution of material adding or removal operation in the model (Fig. 2.3.59).

- ▼ Enable the switch **Application Area "Components and bodies"** so that the operation effect covers the components included in the assembly and also the bodies created in the model.

- ▼ Enable the switch **Application Area "Components"** so that the operation effect covers only the components of the model.

- ▼ Enable the switch **Application Area "Bodies"** so that the operation effect covers only the bodies of the model.

2. Definition of the application area of the selected type — specifying the objects which comprise the applicability range.

Definition of the “Body” application area for material removal operations can be found in Section 2.3.10.3 on p. 219, definition of the “Components” application area— in Section 2.3.10.4 on p. 222. If the application area “Components and Bodies” has been selected, then you should define both the areas— “Components” and “Bodies”.

Fig. 2.3.59. The Properties bar during the creation of a round hole from library

When working with an assembly (*.a3d), the material removal operations have by default the 'Components and Bodies' application area enabled, and the material adding operations—'Bodies'. When working with a part (*.m3d) operations of both types have an application area of 'Components and Bodies'.

The default method to define the application areas 'Components' and 'Bodies' for all material removal operations, except for surface cut-off or sketch, — **Auto determination**. For surface and sketch cut-off operations the default method to define the 'Components' application area is **All Components**, and that of 'Bodies' application area—**Auto Define**.

2.3.10.3. "Body" Application Area

The "Body" application area may include:

- ▼ visible (non-hidden and included into calculation) bodies which intersect with the feature created due to operation,
- ▼ all shown bodies,
- ▼ arbitrary set of bodies.

By default, the application area of an operation is determined automatically: it includes all bodies except for the hidden ones intersecting with the operation-produced feature (it is shown as a ghost before completing the operation).

Thus, if you are working with intersecting bodies, we recommend hiding those of them that should not be included in the application area of the performed operations.

In the examples shown on Fig.2.3.58, the result of cutting with automatic application area determination would be the holes in all three bodies, while the result of pasting shall be a single body combining bodies 1, 2, 3 and the extrusion feature.

If necessary, the scope of any operation application may be set up manually, including all visible bodies or an arbitrary set of bodies.

Methods to define the application area are detailed in Section 2.3.10.3.3.

The set of bodies constituting the operation application area **remains unchanged**. Enabling the display of bodies that were hidden at the time of performing the operation as well as "dragging" bodies in the Design Tree do not affect the application area. Due to this, modeling parts by subtracting one body from another is possible.

For example, you need to construct a part with a complex-shape void. To do this, you can do the following.

1. Create the first body, i.e. the body that will define the part shape, and then hide it.
2. Create the second body, i.e., the body that will define the void shape. While executing operations to create the body, it is possible not to carry out any actions to define their application area, i.e. you may use the default method to define the application area — automatic determination. In this case, only the second body will be included in the application area of all operations.

3. Enable the first body display. This will not change the application area of the second body. In other words, all operations performed in step 2, including, for example, the **Through All** cut operations, will still affect only the second body.
4. Perform the Boolean operation of subtracting the second body from the first one.

To include new bodies in operation application area or exclude existing ones from it, switch to the editing mode of the operation and modify its application area using the control features on the Properties toolbar. These features and methods of working with them are described in the further sections.

2.3.10.3.1. Determination of the "Body" Application Area for Material Adding Operations

While adding material to a model, the 'Body' application area is specified on the **Operation result** tab of the Property panel (Fig. 2.3.60).

Fig. 2.3.60. Setting 'Bodies' application area for pasted extrusion element

The default method of defining an operation application area is the auto determination. The **Auto Union** switch in **Operation Result** group is active in this method.

If necessary, you can set up the operation applicability of range in an arbitrary way. To do this, activate the **Union** switch. The **Application Area** group of features becomes accessible on Properties toolbar.

Methods to define the application area are detailed in Section 2.3.10.3.3.

2.3.10.3.2. Determination of the "Body" Application Area for Material Deleting Operations

- ▼ While cutting shape-generating features, the "Body" application area is specified on **Cutting** tab of Properties toolbar (Fig.2.3.61).
- ▼ While creating a circular hole, as well as at dissection of the model with plane or sketch, the "Body" application area is specified on **Operation Result** tab of Properties toolbar (Fig.2.3.62).

Fig. 2.3.61. Setting 'Bodies' application area for extrusion element being cut

Fig. 2.3.62. Setting 'Bodies' application area for a library hole

The default method of defining an operation application area is the auto determination. In this case, the **Auto Determination** switch is active.

If necessary, you can set up the operation applicability of range in an arbitrary way. To do this, turn off the **Auto Determination** switch. The **Application Area** group of features becomes accessible on Properties toolbar.

Methods to define the application area are detailed in Section 2.3.10.3.3.

2.3.10.3.3. Methods to define the "Body" application area

Auto Determination of the application area indicates inclusion of all bodies, except for the hidden ones and the ones excluded from calculations, intersecting with the feature created as the result of the operation.

- ▼ If no intersections were found between the feature being created and other bodies when adding material to the part, then the feature is created as a stand-alone body.

In this case, the **New Body** switch activates on the **Operation Result** tab.

- ▼ If, upon removing material from the part, no intersections were found between the feature being created and other bodies, the error occurs in the model.

Automatic determination of the operation application area is in a sense preferable to other methods of defining the application area since in the latter case the bodies that do not intersect with the feature being edited may accidentally become included. In this case, the feature cannot be created. The reason for this is that the operation can be performed only if the feature resulting from the operation does actually intersect with the bodies that enter its application area. If the feature does not intersect with at least one of the bodies included in the operation application area, "The objects do not intersect" error occurs in the model.

When auto determination of the application area is disabled, the **Application Area** group of features becomes accessible. It contains two switches: **All Bodies** and **Selection of Bodies**.

- ▼ The **All Bodies** switch serves to include all bodies except for hidden and excluded from calculation, regardless of whether they intersect with the edited feature, or not.

- ▼ **Body Selection** switch serves to specify the bodies that shall be included in the current operation application area. Upon activating this switch, the **List of Bodies** toolbar becomes available. It contains the list of bodies included in the operation application area, and two buttons: **Select All** and **Delete**. To manually add bodies to the application area, select them in the model window or in the Design Tree.

The **Select All** button serves to include all bodies present in the model in the operation application area, including hidden bodies and bodies that do not intersect with the feature being edited.

The **Delete** button serves to exclude body from the application area.

The specific feature of **Auto Determination** and **All Bodies** switches is their functioning only during operation execution. The result of their work is creating corresponding lists of bodies. To verify this, enter the editing mode of the feature created with the **Auto Determination** or **All Bodies** switches disabled. You will see that this switch is off on the Property bar, the **Manual Selection of Bodies** switch is on, and the **List of Bodies** bar contains names of intersected bodies or of all bodies respectively.

The cutting operation (with a plane or by sketch) results in cutting of the bodies which intersect the cut surface when the **Auto Determination** switch is active.

If you need to delete the bodies entirely located on the same side of the cut surface in addition to cut body pieces, use the **All Bodies** switch or specify bodies manually.

2.3.10.4. "Components" Application Area

The "Components" application area may include:

- ▼ those of visible (non-hidden and not excluded from calculation) model components which are intersected by the element created as a result of the operation,
- ▼ all model components,
- ▼ all components except those from library,
- ▼ arbitrarily selected components.

2.3.10.4.1. Setup of Application Area "Components"

To go over to the mode of setting the 'Components' applicability area while performing the operation in the model, click the button **Application Area** on the Advanced Control Panel (Fig. 2.3.59).

On the Property Bar, the elements, enabling selection of the components to apply the current operation to, will appear (Fig. 2.3.63).

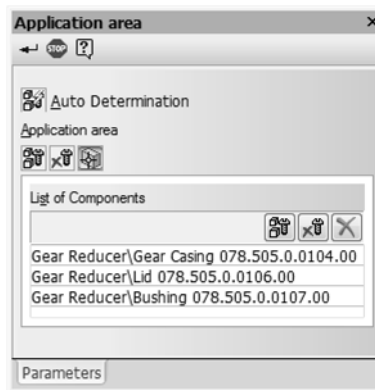

Fig. 2.3.63. The elements to control the application area “Components”

- ▼ To form the application area automatically, activate the **Auto Determination** switch. All the components, except hidden and excluded from calculation, intersecting with the element, being the result of operation (it is shown in the model window as the ghost), will be included into the application area.

A specifics of automatic determination of the application area is that it works only at the time of performing the operation. Its result is a created list of bodies with which an intersection is found when performing the operation. To witness that, go into the editing mode of a feature created using automatic determination of the application area. You will see that the automatic application area determination switch on the Property bar is disabled, the **Manual Selection of Bodies** switch is enabled, and the **List of components** bar contains the names of elements belonging to the bodies, with which there are intersections.

- ▼ To setup the application area in an arbitrary way, disable the switch **Auto Define**. The **Application Area** group of features becomes accessible on Properties toolbar.

- ▼ Enabling the switch **All components** means that the components, which intersect with the edited element, will be found and included into the area of operation application. However, the list of components, unlike auto defining the application area, is not created. Later on, when adding into the model the new components or moving the existing ones, the operation application area will be redefined and, after the model is rebuilt, the shape of components, included into the application area, will change.

- ▼ Enabling of the switch **All Components, save the library ones**, means the same as above procedure of defining the application area, except, however, for the objects inserted from the application libraries (for example, the fasteners from the Library of Standard Items).

- ▼ Enabling of the switch **Selected Components** allows manual selection of the components involved in the operation. To select the components, the panel **List of Components** is used (see Section 2.3.10.4.2). The area of the operation application set in this way is not changed at adding or displacing of the components. To exclude any components from the area of the operation application or add certain components, it is necessary to edit this operation by changing the earlier created list of components.

When finished with defining the application area, click the **Create Object** button on the Special Control Panel. The system will then return to the mode of executing the operation for which the application area “Components” was set up.

2.3.10.4.2. Generating the “Components” Application Area Manually

When defining the 'Components' application area manually, you can select any components in the model:

- ▼ parts,
- ▼ subassemblies,
- ▼ library components,
- ▼ copies of components within array instances.

Components can be selected in the Design Tree or in the Model window. The selected components are highlighted and their names are added to the **List of Components** panel (Fig. 2.3.63). A repeated selection of a component excludes it from the operation application area. If you need to exclude from the application area all the included in it components at once, click by the mouse in any free place of the model window.

A selected subassembly is always included in the operation application area together with all its components. Therefore, if you need to include only selected components of a subassembly into the application area, you need to select just those, watching that the entire subassembly is not selected.

To speed up component selection for the operation application area, you can use the buttons located on the **List of Components** panel.

After clicking the button **Select all**, all model components are included the operation application area: parts, subassemblies and copies of components belonging to array instances. This button is convenient to use if most of components are to be involved in the operation.

After clicking the button **Select all, except library ones**, all model components are included the operation application area, except those inserted from application libraries (*.rtw). If necessary, you can include some of library objects into the application area. To do this, pick them by the mouse in the Design Tree.

The **Delete** button allows to exclude from the application area the components whose names are selected in the list.

Note that an object selected in the list is highlighted in the Model window. This helps control correctness of component selection.

2.3.11. Bodies consisting of separate pieces

Solids in KOMPAS-3D models can consist of multiple disjoint pieces. For example, such a solid can be produced by extruding a sketch containing multiple contours.

It is also possible to divide solids into pieces as a result of cut or trim operation. For example, after inserting a base into a part, you can cut material out of it in a way to leave only those pieces of the base that are needed to construct the part.

There are special icons in the Design Tree that symbolize the presence of solids consisting of multiple pieces (Fig. 2.3.64):

- ! ▼ exclamation sign on the model icon signifies that the model contains solids made up of multiple separate pieces,
- ! ▼ exclamation sign on the operation icon signifies that the process of changing the set of pieces of the solid has been initiated during the operation (see Section 2.3.11.1),
- ▼ a solid icon divided into pieces signifies that the solid is made up of multiple separate pieces.

The icons of solids are displayed in the Tree, if model structure display is enabled in the Tree (see Section 2.1.2.2).

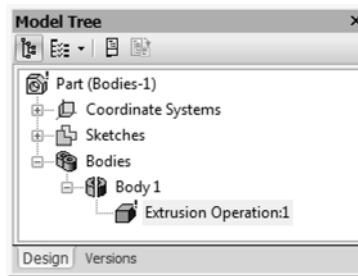

Fig. 2.3.64. The Design Tree of a part containing a solid made up of multiple pieces

The contextual menu, called in the Tree on the icon of a model or a body with the attributes of containing several parts, as well as the contextual menu called in the model window with bodies comprising parts, contain the **Attention** command. After calling this command, a message on presence of bodies consisting of multiple pieces appears on the screen.

Solids consisting of pieces can be made whole applying either of the two methods:

1. Change sketches or operation options that form solids out of pieces in a way that each solid should contain once piece. In this case, all signs of the presence of solids consisting of multiple pieces shall disappear from the Design Tree.
2. Create any new features connecting pieces of solids. In this case, only those signs of the presence of multiple pieces that are related to solids and models shall disappear from the Design Tree, while exclamations on icons of operations shall stay.

In the sheet body made up of multiple pieces, creation of new bends, changes in the state of current bends, or capping of bends are impossible. To perform these operations, a body shall be made single-piece.

2.3.11.1. Selecting pieces that need to be kept

Selection of pieces of a body (or bodies) that need to be kept is performed during the process of changing the set of pieces. This process is started automatically after completing the operation that leads to creation of a body consisting of multiple pieces.

Note that changing a set of parts is possible for bodies constructed in the model itself and impossible for component bodies. In other words, if operation separates component bodies into parts, all these parts remain.

By default, after the start of the process of changing the set of pieces, there is only one option enabled of the Properties Bar: **All**. It means that all the created pieces of the body shall be kept in the model. Body pieces are displayed in the Model window as ghosts.

If you do not need to keep all body pieces but only some of them, disable the option **All**. **List of Parts** (Fig.2.3.65) shall appear on the Property Bar. The list appears as a table, the first column of which contains the number of the body and pieces and the second column contains the option **Keep**.

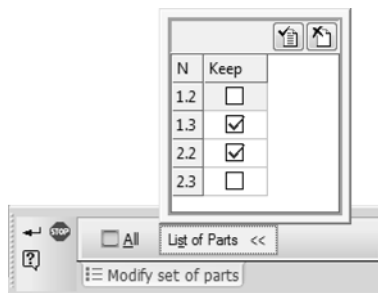

Fig. 2.3.65. Selecting body pieces that need to be kept

Disable options of the parts which will not be used, or specify these parts in the model window. Repeated specifying of the part will include it in the kept ones.

If you need to keep or exclude the majority of pieces, use buttons **Select All Parts** and **Deselect All Parts** that are located above the list.

Having finished the selection of the body parts, click the **Create Object** button. The button is not available if no pieces are kept.

Excluded body parts are as if they are not available in the model: they are not displayed, cannot be used for construction of other objects, not accounted for the MP calculation, not sent to associative model views and resulting files during export to other formats etc.

At the same time information about excluded parts is not deleted from the model file, allowing to change the set of parts in the future.

The process of changing the set of pieces is also initiated after editing the operation that shall result in a body made up of multiple pieces (unless the operation options were changed to result in a solid body).

The icon of the operation after executing or editing of which the process of selecting pieces has been started is marked with exclamation in the Tree. The **Modify Set of Parts** command is present in the context menu of this operation (Fig.2.3.66). It allows restarting the process of selecting pieces resulting from the operation.

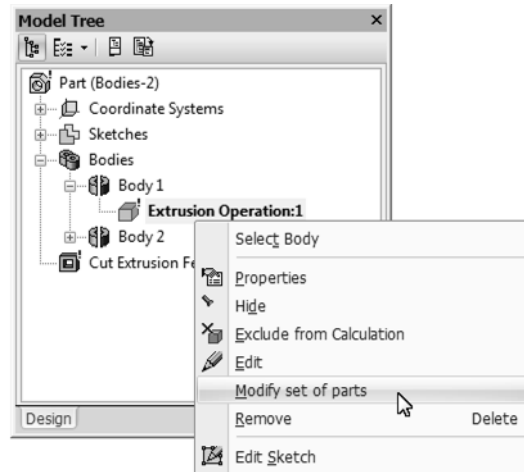

Fig. 2.3.66. Command **Modify Set of Parts**

2.3.11.1.1. Peculiarities of changing the number of the body's parts

1. If the process of changing the set of parts was launched for an operation, and then the number of parts was changed without launching the process, the message about the change in the number of parts will appear on the screen. For example, a sketch containing several contours was extruded with outside inclination. In the process of changing the set of parts, the user chose to retain only some of the body's parts. Then, in the Window of Variables, the value of the variable corresponding to the inclination level was increased so that some of its parts merged. After rebuilding, all parts of the body will be displayed in the model window, and the message about changing the number of parts will appear. If necessary, launch the process of changing the set of the body's parts and choose the required parts.
2. The operation is marked with exclamation only after starting the process of changing the set of pieces. Consequently, the following situation may occur.
The initial result of the operation was an intact body. After editing any object in the model, the operation resulted in a body consisting of multiple pieces. The model and the body receive an attribute of presence of multiple pieces, while the operation does not receive such an attribute because the process of changing the set of pieces was not started. To start the process, you need to enter the operation editing mode and then confirm the creation of an object.

Example 1

Extrusion of a sketch containing a single contour was performed in the model. Then the sketch was edited: a new contour was added into the sketch. Immediately upon exiting the sketch mode, the extrusion feature is displayed in the Model window as consisting of two pieces but the icon of the extrusion feature is displayed in the Tree without exclamation.

Example 2

The model contained a cut extrusion feature that deleted a certain volume of body material but

did not divide it into two pieces. Later in the Variables Window, the value of the variable that corresponds to the depth of extrusion was increased in a way that the cut feature became to fully intersect the body. After rebuilding, the body is displayed in the Model window as consisting of two pieces but the icon of the cut extrusion feature is displayed in the Tree without exclamation.

2.3.12. Multibody Modeling

Multibody modelling is the process of modeling when several bodies are created.

Multibody modelling may result either in one body or in multiple bodies (the case of a multibody model).

Each body during multibody modeling is created in a usual way. Boolean operations can be performed with bodies (see Section 2.3.7 on p. 185).

While executing operations in a multibody model, it is necessary to take into account their scope of application (see Section 2.3.10 on p. 217).

For each body, you can set MP parameters (see Section 2.14.6 on p. 802), the color and surface properties (see Section 2.14.2 on p. 784).

Multibody modeling expands the capabilities of constructing models and lifts the limitation on creating models that can be obtained solely by uniting, subtracting or intersecting bodies. For example, by using multibody modeling, a part may be constructed by combining thin-wall bodies with different wall thickness.

If necessary, the bodies constructed in the model can be saved as individual parts (see Section 2.11.2.3 on p. 689).

Note that body can not be displayed partially. That means that you cannot hide or show, for example, an individual feature pasted to the body. Therefore, after calling the **Hide** or **Show** command on some feature, the entire body which includes the feature gets hidden or shown.

2.3.12.1. Examples of Multibody Modeling Use

Among most typical examples of using multibody modeling are the “multilateral” design approach and creating bodies by subtraction.

The “multilateral” design is a design method in which isolated pieces of a part are created as stand-alone bodies which are merged subsequently. In this way, the intersecting bodies can be united by performing a Boolean operation on them, whereas the non-intersecting ones may be combined by constructing a new body that intersects with them.

Creating bodies by subtraction is the design method in which a body part is formed by subtracting some bodies from others. In this case, you need to create two intersecting bodies the first of which will define the part shape, and the second one— the shape of the void. After that, you will need to perform Boolean subtraction operation on the bodies, subtracting the second body from the first one. This design approach is recommended when creating parts with complex pockets or other cavities made through complex surfaces and using fillets.

It is impossible to copy boolean operation result using the array-creating commands. Therefore, if there should be several identical pockets or cavities resulting from subtraction, you should at first create copies of bodies for subtraction, and then execute boolean operation as many times as required.

2.3.12.2. Displaying a Multibody Model in the Design Tree

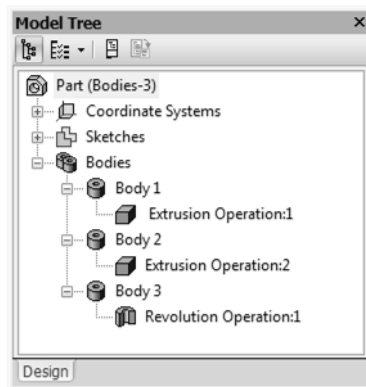

Overall amount of model bodies is displayed in the Design Tree in brackets after its name (Fig. 2.3.67–2.3.69).

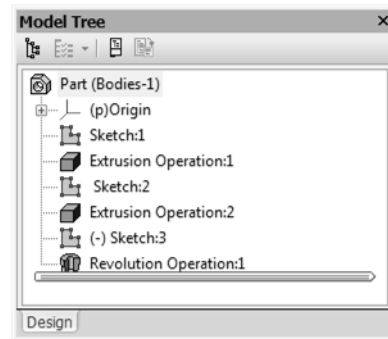

The number of bodies created in this model is displayed in the Design Tree. Number of bodies in components is not displayed.

The Design Tree can be displayed in one of the two types: as a sequence of construction or in form of a model structure (see Sections 2.1.2.1 on p. 106 and 2.1.2.2 on p. 106 accordingly). While working with a multibody part, representation of Tree as a structure is recommended. Rather than displaying of construction order, this method shall provide a better representation of multibody model content and the sequence of its construction (Fig.2.3.67–2.3.69).

- ▼ Body-forming features are grouped into categories that correspond to bodies. Sections have names “Body N”, where N is the sequential number of body (Fig.2.3.67,a).

a)

b)

Fig. 2.3.67. Multibody part in Tree:
a) structure, b) sequence of construction

- ▼ If the model undergoes a Boolean operation over bodies, then it is placed in a category matching the first of the involved bodies. The second body involved in this Boolean operation is displayed as being subject to it (Fig.2.3.68,a).

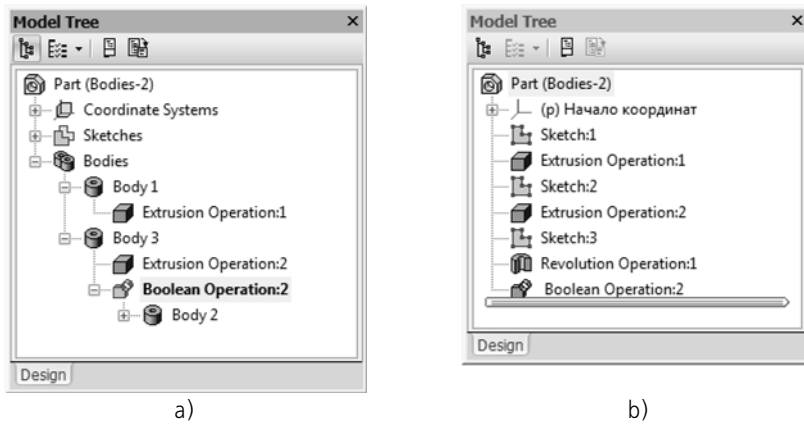

Fig. 2.3.68. Boolean operation over the part bodies:
 a) structure, b) sequence of construction

- ▼ If the model contains a feature combining several bodies into one, then it is placed into a category matching the first of the combined bodies. Other bodies merged through this feature are displayed as subject to it.

Combining features are represented in Tree with special icons (Fig.2.3.69,a).

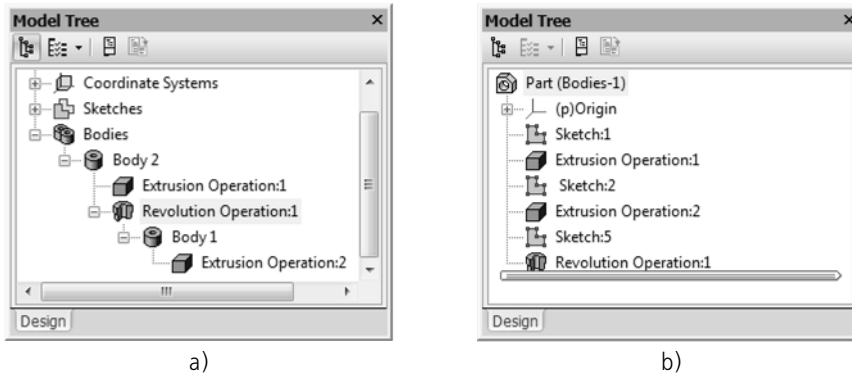

Fig. 2.3.69. Boss feature, combining bodies:
 a) structure, b) sequence of construction

2.4. Sheet bodies

2.4.1. General Information on Sheet Bodies

KOMPAS-3D supports modeling parts created from a sheet material by bending.

Commands for working with sheet bodies are located in the **Operations** menu, and the buttons to call them are on the **Features of Sheet Body** bar (Fig.2.4.1).

Fig. 2.4.1. **Features of Sheet Body** toolbar

Creating a sheet body creation starts with creating a sheet body. The **Sheet body** command (see Section 2.4.2 on p. 243) or **Shell** (see Section 2.4.3 on p. 246) may be used for that. Then elements of sheet body are added to the received sheet body: bends, plates, holes, cuts, etc.

Please note that sheet bodies can be added only to sheet body, built directly in the model (not in any of its components).

A sheet body is a sheet body together with added sheet body features. Bosses of features of any type— extrusion, revolved, sweep, loft — can be attached to a sheet model or cut from such model. Additionally, you can add design elements to a sheet body (fillets, chamfers, ribs, holes, etc.). Any copying operations can also be applied to sheet bodies, plates, holes and cuts.

Fig. 2.4.2. Example of a part made of sheet material

One model can contain one or several sheet bodies. Multibody modelling is detailed in Section 2.3.11 on p. 224. If there are several sheet bodies in the model, they can have the same or different thicknesses.

2.4.1.1. Methods to Work with a sheet body

Any bend existing in a sheet body, can be displayed both in bent and rectified state. The user can at any time change the state of any bend (or a group of bends).

While working with a sheet body, it is possible to display its flat pattern. This is a special display mode, in which the bends selected by the user are shown as bent, while the rest are unbent. If neither of bends is selected, this mode displays a fully unbent sheet body. Switching to the flat pattern mode is possible after setting **flat pattern parameters** — selecting the bends that should stay bent.

Associative views of a model containing a sheet body are created on a drawing in the same way as associative views of a regular body. At the same time, if flat pattern parameters are specified in a sheet body, then it is possible to generate the flat pattern image of that part in the drawing.

If one model has several intersecting sheet bodies, then for their union, subtraction or intersection the **Boolean operation** command shall be used (see Section 2.3.7 on p. 185).

Stamped elements and elements with bends can be created only on those sections of a sheet body, which have the constant thickness (a sheet body with variable thickness can be created, for instance, as a result of uniting of two bodies with different thicknesses).

Please note that “non-sheet” operations in a sheet body may limit or exclude usage of the functional while working with sheet bodies:

- ▼ Some geometry-producing and additional structural elements may prevent changes of bends (see Section 2.4.7.3 on p. 307).
- ▼ Cut and trim operations may result in dividing a sheet body into parts. In each sheet body, which consists of several parts, it is impossible to create new and change existing bends, bends capping and create holes and cuts using the **Through** option. To perform these operations, a body shall be made single-piece.
- ▼ After the scaling operation, a sheet body becomes a “non-sheet” body: it is impossible to add any sheet elements to it or change bend states.

2.4.1.2. sheet body Parameters

A sheet body is characterized by the **thickness of the material** (S) of which it is made.

The bent portions (**bends**) of a part are defined by:

- ▼ **Inner radius** (R),
- ▼ **Bend angle** (α),
- ▼ **Width of bend release** (W),
- ▼ **Depth of bend release** (H).

Fig. 2.4.3. Sheet Body Parameters

A bend may not have any releases.

Besides, any bend has a parameter that defines the flat pattern length of that bend. Depending on the selected method of defining the flat pattern length, this parameter can be the **Neutral Layer Factor**, or the **Bend Amount**, or the **Bend Reduction** (see Section 2.4.1.4 on p. 237). The parameter that defines length of flat pattern of bend, will be further referred to as **flat pattern parameter** of this bend.

Default parameters for all new sheet bodies are defined in the dialog of sheet body properties (See Section 9.2.7.4.8 on p. 1851).

To set up such parameters of operation as sheet thickness, bend width, slope and others, you can use handles (handles are detailed in Section 2.1.4.2.2 on p. 138).

2.4.1.3. Sheet Body Variables and Work with Them

While creating a sheet body in a model (see Section 2.4.2 on p. 243), **sheet body variables** are automatically created in it. Initial values of variables are defined by settings (see Section 9.2.7.4.8 on p. 1851).

Sheet body parameters and their current values are displayed in the Variables window (Fig. 2.4.4):

- ▼ SM_Thickness — sheet thickness,
- ▼ SI_Radius — inner bend radius,
- ▼ SM_Angle — bend angle,
- ▼ SM_BA — bend amount,
- ▼ SM_BD — bend deduction (reduction),
- ▼ SM_K — position coefficient of the neutral layer,
- ▼ SM_H — depth of bend release,
- ▼ SM_W — width of bend release.

Name	Expression	Value	Parameter	Comment
Part (Bodies-1)				
SM_Thickness	1.0	1.0		Sheet body thickness
SM_Radius	5.0	5.0		Bend radius
SM_K	0.40	0.40		Coefficient

v35	SM_H	0.0	Depth of bend relief	

Fig. 2.4.4. Sheet Body Variables

By default, when creating elements with bends and the *Sheet body* element, the parameter values coinciding with values of the corresponding variables are suggested. If this values are **not changed manually**, then after creation of an element the following variables will be automatically assigned to its parameters:

- ▼ *Sheet Body* element:
 - ▼ Thickness = SM_Thickness;
- ▼ Elements with bends
 - ▼ Inner radius= SM_Radius,
 - ▼ Bend angle= SM_Angle,
 - ▼ Release depth= SM_H,
 - ▼ Release width= SM_W,
 - ▼ Bend amount= SM_BA,
 - ▼ Reduction of bend= SM_BD,
 - ▼ Neutral layer coefficient= SM_K.

New variable values of a sheet body in the current model can be defined in the Variables window or when editing a sheet body, to parameters of which variables were automatically assigned (to change the variable value it is required to change the parameter value, e.g. to increase the sheet material thickness).

The changed value of the variable, that is used by different elements, is transferred to all those elements. Thus, you can quickly change dimensions and topology of a sheet body without editing each element individually.

For instance, parameter “radius” in all part bends refers to the variable SM_Radius, and parameter “angle” — to the variable SM_Angle. Initial values of variables— 3 and 90 (Fig.2.4.5).

Variables				
Name	Expression	Value	Param...	Comment
Part (Bodies-1)				
SM_Thic...	1.0	1.0		Sheet body thickness
SM_Radi...	3.0	3.0		Bend radius
SM_K	0.40	0.40		Coefficient
SM_BA	10.0	10.0		Bend amount
SM_BD	0.0	0.0		Reduce bend
SM_Angle	90.0	90.0		Bend angle
SM_H	0.0	0.0		Depth of bend relief
SM_W	3.0	3.0		Width of bend relief
(p)Origin				

Fig. 2.4.5. Initial values of variables and source state of a part

Resulting from change of value of the variable SM_Radius by 1.5, and the variable SM_Angle by 70, all the part bends were rebuilt in accordance with new parameter values (Fig.2.4.6).

Variables				
Name	Expression	Value	Param...	Comment
Part (Bodies-1)				
SM_Thic...	1.0	1.0		Sheet body thickness
SM_Radi...	1.50	1.50		Bend radius
SM_K	0.40	0.40		Coefficient
SM_BA	10.0	10.0		Bend amount
SM_BD	0.0	0.0		Reduce bend
SM_Angle	70.0	70.0		Bend angle
SM_H	0.0	0.0		Depth of bend relief
SM_W	3.0	3.0		Width of bend relief
(p)Origin				

Fig. 2.4.6. New values of variables and a rebuilt part

The automatically created variables can be used in expressions defining the values of other variables and parameters, as well as in sketches.

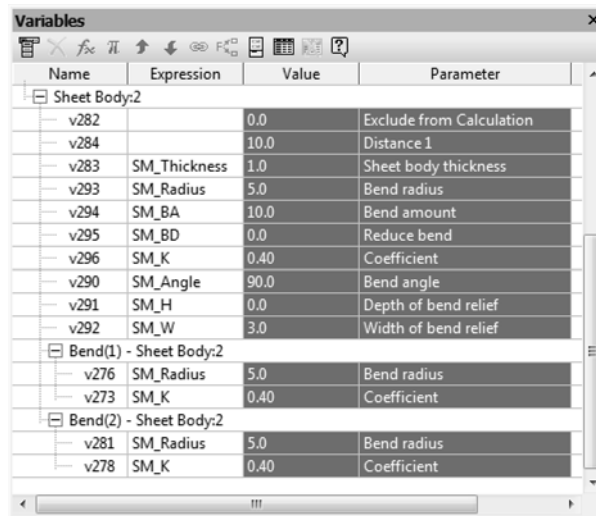

Work with variables and expressions is described in detail in Section 7.1 on p. 1569.

2.4.1.3.1. Peculiarities of Work with Sheet Body Variables

1. It is impossible to change default variables of a sheet body.
2. Editing of a bend, to parameters of which variables were automatically assigned, by changing the value of any parameter **does not affect** the value of the corresponding variable. Resulting from such editing, the bend parameter is assigned a value entered in the corresponding field of the Properties panel, while equality of parameter and variable values is automatically deleted.

3. If a value corresponding to the variable is returned to the parameter as a result of bend editing, then this variable is automatically assigned to this parameter.
4. You can create variables (SM_Thickness, SM_Radius, SM_Angle, etc.) in a model and assign the right values to them even before building a sheet body. The defined values are transferred to the dialog of setting up parameters of a sheet body for the current model and used when creating sheet elements.
5. Bends that have switched off definition of parameters based on the source object (see Section 2.4.4.3.6 on p. 260), are displayed in the Variables window as independent elements subordinate to their source object (Fig. 2.4.7). Parameters of these bends are radius and flat pattern parameter. If the parameter value coincides with the value of the corresponding variable, then this variable is automatically assigned to this parameter:
 - ▼ radius— SM_Radius,
 - ▼ bend amount— SM_BA,
 - ▼ bend deduction (reduction)— SM_BD,
 - ▼ neutral layer coefficient— SM_K.

Name	Expression	Value	Parameter
Sheet Body:2			
v282		0.0	Exclude from Calculation
v284		10.0	Distance 1
v283	SM_Thickness	1.0	Sheet body thickness
v293	SM_Radius	5.0	Bend radius
v294	SM_BA	10.0	Bend amount
v295	SM_BD	0.0	Reduce bend
v296	SM_K	0.40	Coefficient
v290	SM_Angle	90.0	Bend angle
v291	SM_H	0.0	Depth of bend relief
v292	SM_W	3.0	Width of bend relief
Bend(1) - Sheet Body:2			
v276	SM_Radius	5.0	Bend radius
v273	SM_K	0.40	Coefficient
Bend(2) - Sheet Body:2			
v281	SM_Radius	5.0	Bend radius
v278	SM_K	0.40	Coefficient

Fig. 2.4.7. Displaying of bends in the Variables window

If length of the flat pattern of the bend is defined using the table, the flat pattern parameter of this bend is not displayed in panel **Variables**.

If a bend belongs to a sheet body with an open sketch and corresponds to an arc in the sketch of the sheet body, then the *Radius* parameter of that bend does not show in the **Variables** window. And if length of the flat pattern of such a bend is defined using the table, the bend is not displayed in panel **Variables**.

2.4.1.4. Length of the Flat Pattern of a Bend

Length of the flat pattern of the bend can be defined using one of three methods:

- ▼ defining **Position coefficient of the neutral layer**,
- ▼ defining **Bend value**,
- ▼ defining **Bend Reduction**.

Besides, it is possible to use **Tables of bends**, i.e. extraction of the parameter that defines length of the flat pattern (bend value, bend reduction or coefficient of neutral layer), from the table.

The default method of defining a flat pattern length is set in the sheet body properties dialog for new models. For each specific model the default method to define flat pattern length can be changed in the sheet body properties setup dialog for the current model (for setup of default parameters for sheet bodies see Section 9.2.7.4.8 on p. 1851).

Besides that, it is possible to choose the method of defining the flat pattern length for each particular bend (see Section 2.4.4.3.5 on p. 259).

2.4.1.4.1. Definition of Flat Pattern Length Using the Position Coefficient of the Neutral Layer

Flat pattern length is determined on the assumption that there is a **neutral layer** in a bend.

Neutral layer is a part material layer, the length of which is not changed by bending.

The intersection line between the neutral layer of a bend and the plane perpendicular to the bend line is called the **neutral line** (Fig 2.4.8).

Fig. 2.4.8. Incision section by a plane perpendicular to the bend line
(the neutral line is shown by strokes)

The flat pattern length of the cylindrical portion of a bend is defined as the length of the **neutral line** in it:

$$L = \pi \cdot (R + K \cdot S) \cdot (\alpha/180), \text{ where}$$

L—length of the neutral line;

R—inner bend radius;

S is the sheet metal thickness;

K—position coefficient of the neutral layer;

α is the bend angle.

The K coefficient defines the position of the neutral layer:

$$K=t/S, \text{ where}$$

t is the distance from the inner bend surface to the neutral layer;

2.4.1.4.2. Definition of Flat Pattern Length by Setting the Bend Value

Flat pattern length **BA** of the cylindrical portion of a bend (short for *B end Allowance*) is defined by the user. The full flat pattern length **L** of a bend when unbending (see Fig.2.4.9) is calculated by the formula:

$$L = A + BA + B.$$

Fig. 2.4.9. Unbending a bend: a) bend is bent, b) bend is unbent

2.4.1.4.3. Definition of Flat Pattern Length by Setting Bend Reduction

The flat pattern length of the cylindrical part of the bend l is calculated by the formula:

$$l = 2 \cdot a - BD, \text{ where}$$

BD (abbreviation of *Bend Deduction*) — bend deduction; is set by the user,

a — geometrical bend parameter; is defined automatically by the system (Table). 2.4.1).

Tab. 2.4.1. Defining the parameter **a** for different bend angles α

$\alpha < 90^\circ$	$\alpha \geq 90^\circ$
$a = (R + S) \cdot \text{tg}(\alpha/2)$	$a = (R + S)$

The full flat pattern length **L** of a bend when unbending (see Fig.2.4.10) is calculated by the formula:

$$L = A' + B' - BD.$$

Fig. 2.4.10. Unbending a bend: a) bend is bent, b) bend is unbent

For bend angles greater than 90 degrees, the bend deduction value **BD** can be negative.

2.4.1.4.4. Tables of Bends

While defining flat pattern length using the above-mentioned methods, values of the flat pattern parameter (**K**, **BA** or **BD**) can be set randomly, taking into account the existing restrictions.

Dependency of the flat pattern parameter on the material thickness, angle and bend radius can be found, for example, experimentally and put together into tables. In the KOMPAS system, those are called **bend tables** and can be used for defining flat pattern lengths.

A table type is determined depending on its contents:

- ▼ Table of position coefficients of the neutral layer
- ▼ Table of bend amounts;
- ▼ Table of bend deductions.

Tables of bends are stored in files with extension *loa*.

KOMPAS-3D Distribution includes four bend tables:

- ▼ Two tables of position coefficients of the neutral layer:
 - ▼ *Sample1_K_factor.loa*,
 - ▼ *Sample4_K_factor.loa*,
- ▼ Table of bend amounts *Sample2_Bend_allowance.loa*;
- ▼ Table of bend deductions *Sample3_Bend_deduction.loa*.

The described tables contain sample data and are provided as an example. Use them as a template to create your own tables of bends.

Examples of bend tables are located in the folder defined by the KOMPAS-3D system variable *SHEETMETAL*. By default, this folder is *..Sys\SHEETMETAL* relative to the main system installation folder.

Using Tables of Bends

To be able to use a specific bend table in sheet bodies, you need to set this table file first in the sheet body properties dialog (see Section 9.2.7.4.8 on p. 1851) or using command **Operations— Sheet body elements— Table of bends— Select**.

To get the flat pattern parameter for the bends of a new or edited sheet feature of the current part from the table, complete the following steps:

1. On the **Options** tab of the Property Bar, access the **Method of Defining Flat Pattern Length** list.
2. Select a **Bend Table** row from the list.

In the field **Source File** you will see the name of the bend table selected when setting up sheet body properties.

If the **Bend Table** option was enabled when setting up sheet body properties, then, to define flat pattern length for all new bends the default method will be **Bend Table**. In that case, you do not need to perform the described steps.

After entering the values for the angle and bend radius from the bend table, the flat pattern parameter will be set that corresponds to those values. It will be used when unbending a created sheet feature.

When creating the first sheet feature in a model, which uses a bend table, all data from the table is written in the model. No relation is established between the model and the table file.

Any bends, whose flat pattern parameters come from a table, will use the data stored in the document. The source table file can be changed or deleted. That will not affect bend parameters.

Only one bend table can be stored in a model.

Change of the Table of Bends

To use another table file for bends created by a table, you would need to change the bend table stored in the model. For this, do any of the following:

- ▼ Call the command **Operations — Features of Sheet Body — Table of Bends — Select**.
- ▼ Click the **Browse** button in the sheet body properties dialog for the current model (see Section 9.2.7.4.8 on p. 1851).

Changing the bend table we will cause a change in the properties of all sheet body features, whose flat pattern parameter was obtained from the table: this parameter value will be selected from a new table. The icons of modified features will be marked by red “checks” in the Design Tree, signifying that rebuilding is required.

Table of bends stored in a model can be recorded into a file. To do this, call command **Operations — Sheet body elements — Table of bends — Save as...** In the appearing standard Windows dialog specify the filename to write the table to.

Table of bends can be deleted from the model. To delete the bend table from a part, call the command **Operations — Features of Sheet Body — Bend Table — Delete**. In this case, the method of defining the flat pattern length will change automatically for the sheet features created using a table. It will correspond to the type of the used bend table. The flat pattern parameter value will stay equal to the tabulated value for the current radius, bend angle and material thickness.

For example, a feature was created using a table of bend amounts. After deleting the table, this element's **Bend amount** will be defined by the method of defining flat pattern length. The bend amount will be still equal to that previously selected from the table.

A sheet body may contain **features with bend angles determined automatically**. Such elements include:

- ▼ Sheet body with an open sketch (bend angles are defined by the sketched object parameters)
- ▼ Incisions with the preset size less than the minimal one (bend angles are calculated using the formula, see Table 2.4.9 on p. 281).

If these elements use a bend table, then, upon deleting the latter, the elements are processed as follows.

The method of defining the flat pattern length is automatically replaced by the method corresponding to the used table type. The flat pattern parameter takes the **default value** (see Section 9.2.7.4.8 on p. 1851).

If the above-mentioned sheet elements contain bends with switched on definition of parameters based on the source object (i.e., option **Based on the source item** is active, see Section 2.4.4.3.6 on p. 260), the screen displays the bend selection dialog (Fig. 2.4.11).

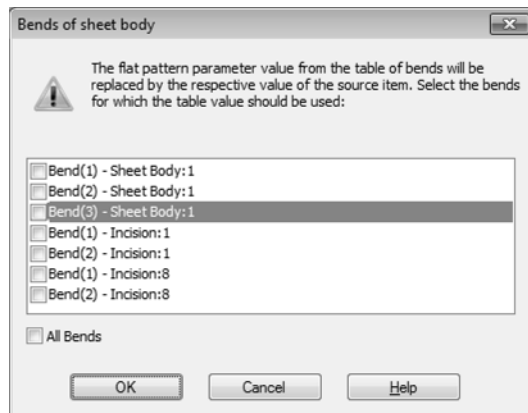

Fig. 2.4.11. Bend Selection dialog

It contains the list of bends having defined properties, which allows setting up processing of those bends upon the table deletion.

In the bend selection dialog, mark the bends, for which you want to preserve the flat pattern parameter obtained from the table. Click **OK**.

For selected bends, the parameter definition by the source object will be automatically disabled. The method of defining the flat pattern length is replaced by the method corresponding to the used table type. The flat pattern parameter of each bend will assume a value selected from the table according to the angle value of that bend.

For other bends, the property of parameters being defined by the source object will be preserved. Therefore, each of them will receive the same parameters as the source object, regardless of the bend angle.

Format of table of bends

A Bend Table is a text file with the *.Joa* extension. Table files can be viewed and edited using any text editor, such as Windows Notepad. Following is an excerpt from a table of position coefficients of the neutral layer.

Table Type — the table of K coefficients

1

Interpolation — apply linear interpolation

1

<0.5> 1.0 2.0 3.0

0.0 0.375 0.415 0.439

360.0 0.375 0.415 0.439

<1.0> 1.0 2.0 3.0

0.0 0.350 0.375 0.398

360.0 0.350 0.375 0.398

Bend tables are created according to the following rules.

- ▼ The measurement units are not entered in the table. Linear values to measure it in millimeters, angular in degrees.
- ▼ Lines starting with the “#” character are comments.
- ▼ The table may contain empty lines. Those are ignored when processing the table.
- ▼ The first value in the table defines its type:
 - 1 — the table of **K** coefficients;
 - 2 — the table of bend amounts **BA**;
 - 3 — the table of bend reductions **BD**.
- ▼ The second value governs use of interpolation for finding intermediate parameter values:
 - 0 — do not apply interpolation;
 - 1 — apply linear interpolation.

If interpolation is allowed then the table is used as follows.

- ▼ If the specified values for the sheet body thickness, radius and bend angle exactly match a table entry, then the flat pattern parameter is obtained from the table.
- ▼ If the specified value of the thickness, radius or bend angle does not match any entry in the table, then the flat pattern parameter is calculated using the linear interpolation.

If interpolation is not used and the specified value of the sheet body thickness, radius or bend angle does not match any entry in the table, then the bend cannot be created. The respective sheet feature is marked in the Design Tree as failing. To fix the failure, you need to bring the bend parameters to a match with the table or select another bend table.

- ▼ Bend Table consists of several **blocks of data**. Each block contains the values for the parameter **K**, **BA** or **BD** for various thicknesses, radii and bend angles. The block structure is the same.

- ▼ The sheet material thickness is constant throughout a data block. Its value is entered in brackets. For example, in the above table fragment, the thickness value is in the upper-left corner of the block.
- ▼ The first line of the block contains bend radius values. Those are positioned in the ascending order left to right.
- ▼ The left column of the block contains bend angle values. Those are positioned in the ascending order top down.
- ▼ Blocks in a table are positioned in the order of increasing material thickness.
- ▼ Values in a table are separated by spaces or tabs.

If a table is used, then the values are not extrapolated: if the thickness, bend radius or angle is outside the range of table arguments, then an error message is displayed.

2.4.1.5. Chamfer

While building such sheet elements as bends (see Section 2.4.4 on p. 252) and stamp elements (see Section 2.4.8 on p. 311), the user can switch on or off display of the phantom on the screen in his discretion.

To manage display of the phantom for the current (created or edited) sheet element, button **Display element phantom** is used in the Special Control Panel.

The ghost of a sheet feature is the wireframe image of the feature with the current parameters. Upon changing settings, the ghost dynamically updates.

If no ghost is displayed (while the **Show Element Ghost** button is pressed) means that the sheet feature cannot be created with current settings.

Using ghost makes a model creation more convenient, since that supports a visual inspection of the creation result. There are cases, however, (for example, when creating beats) when a sheet feature is rather complex, and its ghost drawing (or updating) is slow. In such cases, we recommend switching off the ghost display to speed up work.

2.4.2. Sheet Body

It is created by extruding a sketch in the direction perpendicular to its plane.

Before creating a sheet body, you need to create a sketch in the model, which will define the body shape.

2.4.2.1. Sketch Requirements

Requirements to a closed sketch of a sheet body:

- ▼ Sketch objects can be a part of one or several contours,
- ▼ If there are several contours, one of them must be the outer one and the rest must be nested in it.
- ▼ only one level of nesting is permitted for contours.

Requirements to an open sketch of a sheet body:

- ▼ sketch objects should comprise one contour,
- ▼ a sketch may consist of lines and circle's arcs only,
- ▼ arcs must be connected with lines and other arcs in tangent points.

2.4.2.2. Creating Sheet Body

To create a sheet body in a model, call the **Sheet body** command.

The command **Sheet Body** is available, if at least one sketch is selected.

Set sheet body parameters in the tab of the Properties panel **Parameters**.

If there several bodies in a model, in addition to parameter setup setting of operation application area can be necessary. For this, the **Operation Result** tab of the Properties panel is used. Detailed information on adding material operations application area set it is contained in Section 2.3.10.3.1.

Having finished setup, confirm performance of the operation.

In Window model a sheet body will be displayed with the preset parameters, and the Design Tree will display an image of a sheet body.

After creation of a sheet body, the model forms a certain set of variables (for more information see Section 2.4.1.3 on p. 233).

2.4.2.2.1. With the closed sketch

If the sketch is closed, it is necessary to set its following parameters to build a sheet body.

- ▼ Direction extrusion of the sketch. The forward direction is shown by the arrow in the Model window. For the Direction option group serves to switch the **direction**.

- ▼ Sheet body thickness. In fact, the thickness is the distance of extruding the sketch.

- ▼ Definition of length of the flat pattern of the bend (see Section 2.4.4.3.5 on p. 259). If the flat pattern length is taken from the table of bends, you can change the default table by pressing button **Select another table of bends**.

a)

b)

Fig. 2.4.12. Building of a sheet body based on the open sketch: a) sketch, b) sheet body

2.4.2.2.2. With the open sketch

The following is special about creating a sheet body based on an open sketch:

- ▼ Line segments in the sketch make the flat portions of the sheet body,
- ▼ Arcs in the sketch make bends of the respective radii,
- ▼ Angles in the sketch a contour make bends with the user-specified inner radius.

Select direction and depth of extrusion. This is done in the same way as when building extrusion features (see Sections 2.3.2.4.2 on p. 156 and 2.3.2.5 on p. 157).

Select direction to add material: outside or inside relative to the surface, formed by moving the sketch in the indicated direction.

Enter the thickness of the material layer to be added (sheet body thickness) in the **Thickness** field.

Enter the inner **radius for bends** corresponding to corners in the contour, in the Bend radius field (Fig. 2.4.13).

The zero bend radius is not allowed. The minimum value is *0.0002mm*.

Fig. 2.4.13. Building of a sheet body based on the open sketch:
a) sketch, b) sheet body

Set up the definition of the flat pattern length of the bend (see Section 2.4.4.3.5 on p. 259). If the flat pattern length is taken from the table of bends, you can change the default table by pressing button **Select another table of bends**.

The option **Unbend** controls the state of a sheet body. If it is enabled then construction will result in unbend sheet body. When the option is switched on, all the bends of the sheet body are unfolded.

Icon an unfolded sheet body is marked in the Design Tree by the sign “unfolded”. Management of the attribute “unfolded” for a sheet body is performed in the same way, as for other sheet elements that contain bends (see Section 2.4.4.3.4 on p. 258)

Bends made as a result of building of a sheet body with the open sketch, are not different from bends made using special commands. Bends of a sheet body are displayed in the Design Tree in the same way, as other bends (see Section 2.4.4.2 on p. 253), any bend of a sheet body can be edited (see Section 2.4.4.3.6 on p. 260).

2.4.3. Shell

The shell is formed by moving the sketch in the direction perpendicular to its plane and by adding thickness of the resulting surface (Fig.2.4.14).

Fig. 2.4.14. Creating a shell based on the closed contour:
a) sketch, b) shell

The sketch may be both closed and open contour. If the contour is closed, the shell will automatically be cut by its height. Gap value and position can be specified by the user. There are several methods of cutting the shell's edges.

Bends with specified radius are automatically constructed in the shell's contour corners.

You can perform the same operations with respect to the shell as to a sheet body: unbending/bending, creation of cuts and holes, incisions, beats, and so on.

The shell sections that correspond to curved portions of the sketch that are not circle arcs can be unbent as ordinary bends. At the same time, such sections result not from bending operations, but from operations of deforming; the result of their unbending is conditional to a certain extent and does not depend on the parameter that defines the flat pattern length and value of the parameter.

2.4.3.1. Requirements to the sketch of the shell

- ▼ Sketch objects should comprise one contour. No smooth mate between contour objects is required.
- ▼ A contour can be closed or open.
- ▼ The contour shall not have self-intersections.

2.4.3.2. Shell construction

Before creating a shell you need to create a sketch in the model, which will define its shape.

To create a shell in the model, call the **Shell** command.

Complete the following steps.

1. Select the sketch.

Sketch can be specified prior to calling the command.

2. Set the following parameters:

- ▼ **shell parameters**, see Section 2.4.3.2.1,
- ▼ **base weld parameters** (see Section 2.4.3.2.2),
- ▼ **parameters of the joint's welds and gap** (for a shell with a closed sketch), see Section 2.4.3.2.3,
- ▼ **gap position** (for a shell with a closed sketch), see Section 2.4.3.2.4.

If there several bodies in a model, in addition to parameter setup setting of operation application area can be necessary. For this, the **Operation Result** tab of the Properties panel is used. Detailed information on adding material operations application area set it is contained in Section 2.3.10.3.1.

All parameter values, once entered or modified, are immediately displayed on the screen as the ghost of the extruded feature. A ghost allows a visual control over parameter accuracy.

To set such parameters as direction and distance of the construction, wall thickness, slope angle, bend radius, gap width and position, you can use hot points (for more information about hot points, see section 2.1.4.2.2 on p. 138).

3. Click **Create Object** button to complete the construction.

Construction result— new body, pasted or cut element— appears in the graphic area.

The shell's icon appears in the Design Tree.

When creating a shell, the model forms the same set of variables as while creating a sheet body (for details see Section 2.4.1.3 on p. 233).

2.4.3.2.1. Shell parameters

To create a shell, it is necessary to set up the following parameters.

- ▼ **Direction of plotting.**

The forward direction is shown by the arrow in the Model window. **Direction** switch group serves to change the direction.

- ▼ **Plotting distance.**

To select the method for specifying the distance, list **Method** is used. The following methods are available: **At Distance**, **To Vertex** and **Up to Surface**. Parameters are defined in the same way as when definition of the extrusion depth (see Sections 2.3.2.5.1 on p. 157, 2.3.2.5.3 on p. 158 and 2.3.2.5.4 on p. 159).

- ▼ **Draft angle.**

To define the slope direction use the **Draft angle** switch group, to define the angle of a slope — **Angle** field.

▼ Shell thickness.

To change the direction of adding the material, the switch group **Direction for thickness** is used, while to add the width value — the **Thickness** field.

▼ Bend Radius.

Bends of the specified radius are built in the joints of the contour segments.

Depending on the selected thickness direction, a bend will be created, whose outer or inner radius is equal to the specified value.

Fig. 2.4.15. Bend radius of shell with a slope

Possible reduction of the shell with a slope radius should be taken into account. Construction is performed if the current thickness radius (lower than the bend radius) has an admissible value. The minimum radius value is *0.0002 mm*.

- ▼ **Flat Pattern Parameters** (see Section 2.4.1.4 on p. 237). These parameters can only be applied to shells with the contour in sketch containing segments and/or arcs (if the contour includes other objects, flat pattern parameters do not affect unbending of bends formed by these objects).

2.4.3.2.2. Base Weld parameters

Fig. 2.4.16. Shell's base welds'

Parameters of the shell's base welds' are specified in the **Weld** tab of the Property bar.

Select a type of the shell's base welds' form in the group **Base welds**.

If the **Perpendicular to the sheet's plane** switch is on, the welds are cut perpendicular to the shell's flat pattern plane (Fig.2.4.17, a).

If the **Matching base surfaces** switch is on, the welds are cut parallel to the sketch plane (Fig.2.4.17, b).

Fig. 2.4.17. Base welds on the conical shell: a) Perpendicular to the sheet's plane; b) Matching base surfaces (by At Distance method); c) Matching base surfaces (by Up to Surface method)

The system constructs base welds as follows.

Sketch contour is extruded at the distance, specified in the **Method** group. Thickness is added to the resulting surface— inside or outside. The welds are cut by the surfaces, perpendicular to the shell's surface, or by parallel surfaces, one of which coincides with the sketch plane.

If the extrusion method **To surface** is selected, the **Matching base surfaces** method will mean cutting one edge by the sketch's plane and another— by the surface (Fig.2.4.17, c).

2.4.3.2.3. Parameters of the joint's welds and gap

For shells based on the closed contour, you need to specify parameters of the joint's welds and gap value.

Fig. 2.4.18. Joint's welds of the shell

Enter or set by meter the gap size (distance between edges) in the **Gap** field in the **Edges** tab of the Property Bar. A zero value cannot be set.

In group **Joint's welds** select an option of joint's welds.

When selecting the method **Perpendicular to the sheet's plane** switch is on, the welds are cut by the surfaces, perpendicular to the shell's¹ surface (Fig. 2.4.19, a).

When selecting the method **Parallel to each other**, the welds are cut by parallel surfaces in the direction of the gap (Fig. 2.4.19, b).

1. The edge's surface is constructed so that it is perpendicular to the shell's surface along the whole gap. Edges of a non-flat shell with gap slope are linear surfaces, while in other cases the shells' edges are flat.

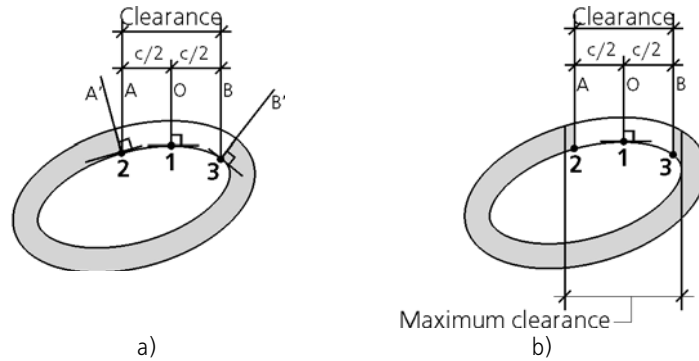

Fig. 2.4.19. Joint's welds on the shell:
a) Perpendicular to the sheet's plane; b) parallel to each other

The maximal acceptable value of the gap depends on its location on the shell— the gap should not protrude beyond the internal wall in the direction which is perpendicular to the gap direction (see Fig.2.4.19, b). Gap position on a shell can be changed, see Section 2.4.3.2.4 on p. 251.

If a contour is not closed, then the welds are always cut perpendicular to the sheet's plane.

Weld construction and gap measuring

When the shell has no slope, the system constructs joint's welds as follows.

1. In the plane parallel to the sketch's plane and crossing the shell, intersection lines are built for the plane and the shell (Fig.2.4.19). As a result, two equidistant curves are obtained.
2. In the **t1** gap's central point, the **O** plane is constructed perpendicular to the curve's tangent, as is shown on the figures.
3. At distances equal to half of the gap's value, which are indicated as $c/2$ on the figures, two planes **A** and **B** parallel to it are constructed. The planes intersect the curve in points **p2** and **p3**.
4. The edges' surfaces are built:
 - ▼ When selecting the method **Parallel to each other**, the welds are cut by parallel surfaces **A** and **B** (Fig. 2.4.19, b),
 - ▼ when selecting the **Perpendicular to the sheet's surface** method, **A** and **B** planes are constructed perpendicular to tangents in **t2** and **t3** points (Fig.2.4.19, a), while the edges are cut by these planes.

To create **t2** or **t3** points, the system selects the curve with the least curve radius on the gap's sections (Fig.2.4.20).

Fig. 2.4.20. Aside from the joint, when placing the gap on the shell's bend without a slope section by **Perpendicular to the sheet's plane** method

If the shell has a slope, joint's welds are created as in the case of the shell without slope, except for the case when gap is created on a non-flat part using the **Perpendicular to sheet surface** method. In this case, the edge is a linear surface whose generating line is perpendicular to the external and internal surfaces of the shell (Fig.2.4.21).

Fig. 2.4.21. Joint's welds when placing the gap on the conical shell by **Perpendicular to the sheet's plane** method

The gap is measured in the shell projection on the plane, parallel to the sketch plane.

The gap value is equal to the minimal distance between the edges in the direction of the tangent to the curve in the gap's point (Fig.2.4.20 and 2.4.21).

2.4.3.2.4. Gap Displacement

The displacement is set from the initial position of the gap— a point in its center— to the same point in the new position. In default position of the gap, its offset is zero.

To set the displacement, select the method in the **Gap displacement** group of the **Edges** tab of the Property Bar, and then enter the value for the displacement.

▼ **By Parameter U** — by the relative offset from the initial to the new position of the gap. The **U Parameter, %** field is used to set the percentage value of the contour length in the sketch.

▼ **By the length** — by the length of the contour from the initial to the new position of the gap. The **Length** field is used to specify the absolute offset in the length measurement units.

▼ **Angle of the position** — by the central angle from the initial to the new position of the gap. Variant is available if shell contour is a circle. The **Angle** field is used to set the central angle of the arc in angle measurement units.

Fig. 2.4.22. Gap displacement:
a) by parameter U or by the length; b) by the central angle

Enter or specify by counter the value of the offset parameter.

When moving the point by mouse, the parameters are calculated and put to these fields.

During construction, you can switch between the options. In this case the offset value will be calculated and displayed in the units of the respective selected option.

2.4.4. Bends

Bend is the cylindrical portion of a sheet body (Fig. 2.4.23).

Fig. 2.4.23. Example of a bend in a sheet body

Bends can be formed in a model by two methods:

1. while creating a sheet body based on the open sketch (see Section 2.4.2.2.2 on p. 244);
2. by using the commands

▼ **Bend,**

▼ **Bend by Sketch,**

▼ **Bend by Line,**

▼ **Release.**

This section is devoted to bends received by the second method. Subsection 2.4.4.3 contains the description of general methods to create these bends. Subsections 2.4.4.4, 2.4.4.5, 2.4.4.6 and 2.4.4.8 describe additional methods that can be used when working with commands **Bend**, **Bend by line**, **Incision** and **Bend by Sketch**, respectively.

Bend creation, as well as corner capping commands can not be applied, if a sheet body comprises several parts (for example, if a body is divided by the cut operation). To create bends, modify a body to make it single-piece by editing existing elements or creating new elements joining all parts.

2.4.4.1. Terms and definitions

To create a bend, it is necessary to have the **bend line** — a linear object that defines position of the bend in a sheet body.

A flat external or internal face of a sheet body that contains the bend line, is called the **basic face** of this bend.

If the part is bend in the direction towards the base face, then the bend direction is considered **direct**. When bending towards the opposite side, the bend is considered to be in the **reverse direction**.

Fig. 2.4.24. Bend direction: a) basic face and bend line, b) forward-direction bend, c) back-direction bend

2.4.4.2. Display of bends in the model's Design Tree

Icons of bends are located in the Design Tree in “branches” of their **source objects**, those sheet elements that contain them (Fig. 2.4.25).

Fig. 2.4.25.

Some elements, for example, an incision, may refer to several bends. To view the list of bends, expand the “branch” of the Design Tree, corresponding to the original sheet feature.

Each bend is automatically assigned a name. The name contains the ID number of the bend in the sheet feature and that feature name.

The context menu of the bend is practically similar to context menu of other sheet elements.

Using it, you can set up properties of a source element, and also view object relations and attributes.

The **Edit element** command starts up the editing process for the selected bend (see Section 2.4.4.3.6 on p. 260).

Exclude from **Calculation/Include into Calculation** affect the entire feature containing the selected bend, while the commands **Hide/Show** act on the entire part body.

2.4.4.3. General Methods to Build Bends

After calling any of the commands to create bends, the Properties panel displays control elements that allow to set up various parameters of bends.

Initially, these parameters (angle, radius, etc.) coincide with the default ones for the given model (see Section 2.4.1.3 on p. 233). If those are left unchanged, then default variables will be assigned to the parameters. In the future, this will help quickly changing parameters of same-type bends. You can find more information on working with variables in the sheet body in Section 2.4.1.3.

To set numerical parameters for bends, you can use typical points (see Section 2.1.4.2.2).

To fix the created bend, press button **Create object** in the Special Control Panel.

A new feature will be added to the sheet body being developed, and the respective icon will appear in the Design Tree:

▼ Bend

▼ sketch bend,

▼ bend by line,

▼ incision.

You can create several components of the same type (bends, bends by line or incisions) without exiting the command. To create the next element select its source object (or objects); if necessary modify parameters of the operation and click the **Create Object** button.

If you need to build a few elements in sequence with the same parameters, perform the following operations. Click the **Object Auto Create** button on the Advanced Control Panel after you have created first object with correct parameters. Then select source objects for new elements. They will be formed automatically, i.e. without waiting for confirmation of creation.

To complete building of elements, press button **Interrupt command** in the Special Control Panel.

2.4.4.3.1. Direction of count and interpretation of the angle value

When creating a bend, the angle can be counted in either direction from the base face. The **forward** (“direct”) **direction** of counting the angle is outward with respect to the part’s body. This direction is defined by the system automatically and is indicated by a ghost arrow in the Model window.

To select the angle direction — **Forward** or **Reverse** — activate the appropriate switch in the **Direction** group.

The value entered in the **Angle** field can be interpreted as follows

▼ **Bend angle** or

▼ **Appending Angle.**

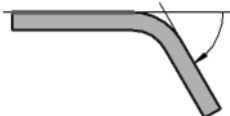

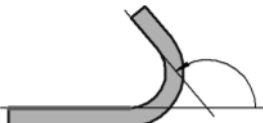

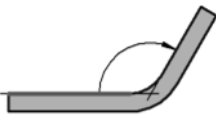

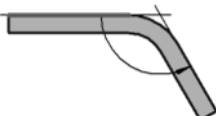

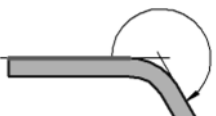

To select interpretation of the angle value, activate the right switch in group **Angle sense**.

Direction of bend, direct or back one (see Fig.2.4.24, b, c) depends both on the direction of angle count and its interpretation (see Table). 2.4.2).

Tab. 2.4.2. The scheme of creating a bend depending on the angle counting direction and sense*

	 Forward angle counting direction	 Reverse angle counting direction
 Bend angle		
		
 Complimentary angle		
		

* The scheme shows the part projection (mapping) on the plane perpendicular to the bend line. The base face projection is shown as a thickened line.

You cannot create a bend with the complimentary angle equal to 180° , since that means no bending: Bend angle is equal 0° .

If the angle sense is the bend angle, then the angle counting direction is the same as the direction of the resulting bend.

If, on the other hand, the angle sense is complimentary, then these directions will call in side only with the angle values being within the range from 0° to 180° . When the complimentary angle values are in the range from 180° to 360° , then the direction of the resulting bend is opposite to the selected direction of counting the angle.

E.g. Figure 2.4.26 the bend is displayed in the **back** direction. The angle of the bend is equal to 250° , it has the **complimentary** sense and is applied in the **opposite** direction.

Fig. 2.4.26. Bend in the back direction

2.4.4.3.2. Radius of the Bend

To select the method to set radius, activate the right switch — **Internal radius** or **External radius** — in group **Method to set radius**.

Depending on the chosen method of defining the radius, a bend will be created, whose outer or inner radius is equal to the specified value.

Minimal value of internal radius — $2 \cdot 10^{-4}$ mm. The inner and outer radii are related as follows:

$$R_{\text{outer}} = R_{\text{inner}} + S,$$

where S is the material's thickness.

Therefore, the minimum value of the outer radius is equal to the sum $(S + 2 \cdot 10^{-4})$ mm.

2.4.4.3.3. Angle Release

If the created bend is located relative to the adjacent bend (bends), for instance, as shown in Fig. 2.4.27, you can use the release of angle.

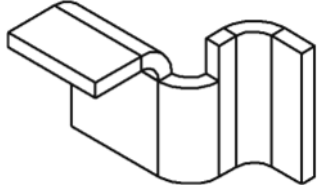

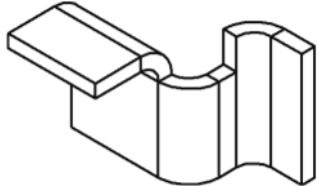

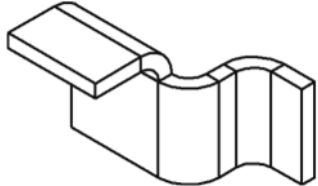

Fig. 2.4.27. Example of location of bends, that allows to use release angle: the flat ring face of the created bend1 partially coincides with the flat rectangular face of the adjacent Bend 2

Three release methods are available (Table 2.4.3). To select the right method, activate the corresponding switch in the tab **Release** of the Properties panel.

Tab. 2.4.3. Methods to release bend angles

	The value of option Release of angle	Construction result*
	Bend proper	
	Bend and its extension	
	All bends	

* This column presents the results of use of various methods to release an angle when building Bend 1 (see Fig.2.4.27).

Use of the release angle in the **Bend** command is subject to the following specifics.

1. Release of the angle is possible only if the line of the bend being created is perpendicular to the lines of the adjacent bends.

2. To enable the release, you need to activate the '**Release angle**' switch on the tab **Release** of the Property Bar. After that, the release type switches will become available.

2.4.4.3.4. States of bends

A bend can be created either in the bent or in the unbent state. The state of a sheet element is managed by option **Unfold**. If it is switched off, the result of building will be a sheet element with folded bends (Fig.2.4.28, b). If the option is switched on, bends of a sheet element will be unfolded (Fig. 2.4.28, c).

Fig. 2.4.28. Building of a bend: a) basic face and bend line, b) folded bend, c) unfolded bend

The unbent sheet feature icon is marked by the “unbend” glyph in the Design Tree.

- ▼ unbent bend,
- ▼ unbend bend by sketch,
- ▼ unbent bend by line,
- ▼ unbent incision.

The attribute “unbent” can be managed both using option **Unbend** (while creating or editing a sheet element) and commands **Unbend** and **Bend** in the context menu of a sheet element in the Design Tree. Upon calling one of them for some element, the other command appears in its context menu. When multiple elements are selected, both commands are available (Fig. 2.4.29).

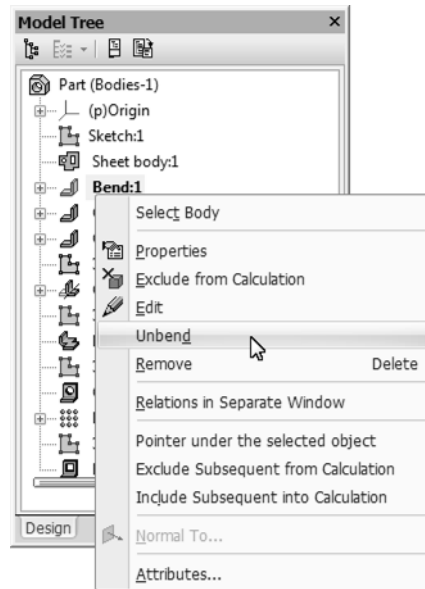

Fig. 2.4.29. Commands **Bend** and **Unbend** in the Bend Contextual Menu

There also exist special commands to edit a sheet body, that allow to change the state of one or several bends (see Section 2.4.7.1 on p. 302).

2.4.4.3.5. Setup of definition of flat pattern length

To set the method to define length of the flat pattern of the bend, open the list **Flat Pattern** and select the right line in it:

- ▼ **Coefficient,**
- ▼ **Bend amount,**
- ▼ **Reduce bend,**
- ▼ **Table of bends.**

The procedure to define flat pattern length for each of the methods is considered in detail in Section 2.4.1.4 on p. 237.

Depending on the chosen method, a field will appear on the Property Bar for entering the value of the flat pattern parameter (**Coefficient**, or **Amount**, or **Reduction**) or a field for selecting a bend table file.

By default, the bend table file is used that was selected in the sheet body properties dialog for the current model. Selection of another table of bends for the current model is described in Section *Change of the Table of Bends* on p. 240.

2.4.4.3.6. Editing of Bend Parameters

By default, bend parameters correspond to those set during setup of a sheet body. Part of parameters for a specific bend can be changed. To edit a bend, select it in the Design Tree and call the command **Edit Feature** from the context menu or from the **Editor** menu.

The Properties panel will display elements that allow to set up the bend (Fig. 2.4.30). By default, option **By Source Item** is switched on. This means that bend parameters should be the same, as for the source object.

To define individual bend parameters, enable the option **By Source Item**. After that, other control elements will become available.

You can change the following bend parameters:

- ▼ Method of defining radius,
- ▼ Bend radius value,
- ▼ Method to define flat pattern length and its parameters.

Other bend properties correspond to those of the source object.

Fig. 2.4.30.

You can neither alter the method of defining the radius nor change its value when editing bends of a sheet body with an open sketch, corresponding to arcs in the sketch of the sheet body.

Bends with disabled parameter definition by the source object are displayed in the Variables window as standalone elements dependent on their source object (see Section 2.4.1.3.1 on p. 235, item5).

2.4.4.4. Bend

You can create a bend along the edge of the sheet body. The edge must be straight and belong to an outer or inner flat face of the sheet part.

The indicated edge will be considered the bend line, and the face that contains it (external or internal) as the basic face of the bend (Fig. 2.4.31).

Fig. 2.4.31. A bend along the edge: a) basic face and bend line, b) result of building

To add to a sheet body a bend along the edge, call **Bend** command.

Indicate the edge, along which the bend is to be located.

Select the direction of count and angle interpretation (see Section 2.4.4.3.1 on p. 254).

Indicate the value and the method of defining bend radius (see Section 2.4.4.3.2 on p. 256).

Set up release of angle (see Section 2.4.4.3.3 on p. 256).

Select the bend state (see Section 2.4.4.3.4 on p. 258).

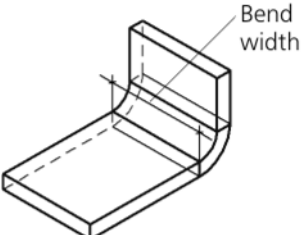

Set up the definition of the flat pattern length of the bend (see Section 2.4.4.3.5 on p. 259).

The phantom arrow (that indicates the forward direction of angle count) is located at the **left end** of the edge. The bend side that is closer to the left end of the edge, is also considered as **the left one**, while the opposite bend side— as **the right one**. Left and right sides are to be distinguished when setting up the location of the bend and parameters of its lateral sides.

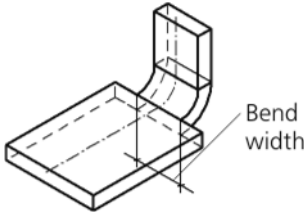

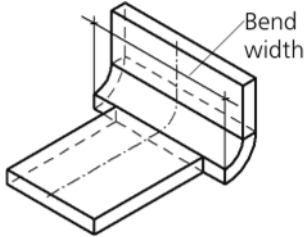

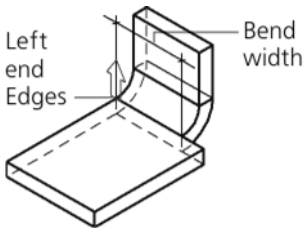

2.4.4.4.1. Bend Placement

When creating a bend, there are different choices for positioning it on an edge. To specify the bend position, select the desired option from the **Location** list (see Table 2.4.4). Depending on your choice, the fields appear in the Property Bar for entering the bend width or its offsets from the edge ends.

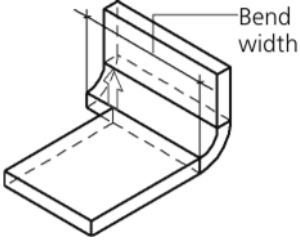

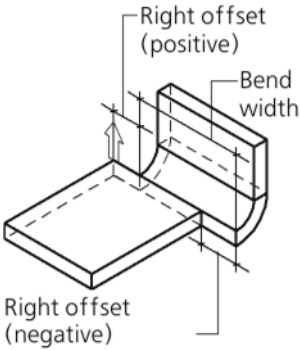

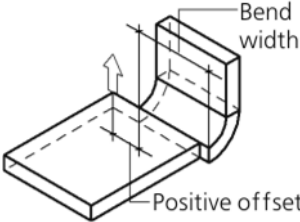

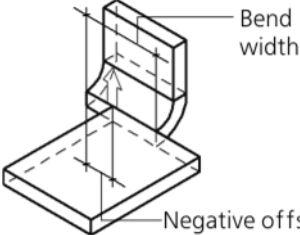

Tab. 2.4.4. Bend location options

	The value of option Location	Rules to locate the bend and define its width	Construction result
	Through all length	The width of the bend is equal to the edge length.	

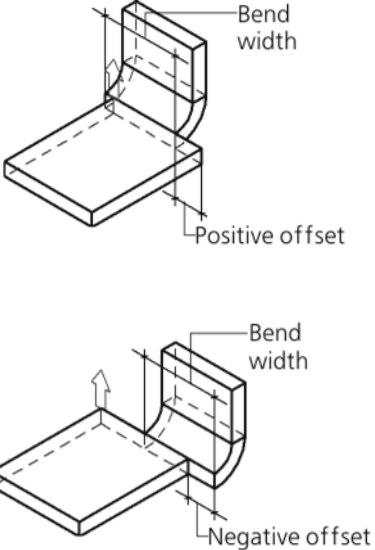

Tab. 2.4.4. Bend location options

The value of option Location	Rules to locate the bend and define its width	Construction result
	<p>Centered</p> <p>The bend width is entered in the Width* field. The bend is positioned centered by the edge midpoint.</p>	
	<p>Left</p> <p>The width value is entered in the Width* field. The bend is positioned so that the left end of the edge lies in the plane of the left side of the bend.</p>	
	<p>Right</p> <p>The width value is entered in the Width* field. The bend is positioned so that the right end of the edge lies in the plane of the right side of the bend.</p>	

Tab. 2.4.4. Bend location options

The value of option Location	Rules to locate the bend and define its width	Construction result	
	Two offsets	<p>The bend width is automatically defined as the difference between the edge length and the total offset amount^{**}. The right and left offset values are entered in the fields Offset 1 and Offset 2, respectively. The bend position is determined by the offset dimensions.</p>	
	Offset at left	<p>The bend width and the offset amount are entered in the fields Offset^{***} and Width[*]. The bend is positioned so that the distance from the left end of the edge to the left side of the bend is equal to the specified offset value.</p>	
			
			

Tab. 2.4.4. Bend location options

The value of option Location	Rules to locate the bend and define its width	Construction result
	<p>Offset at right The bend width and the offset amount are entered in the fields Offset^{***} and Width[*]. The bend is positioned so that the distance from the right end of the edge to the right side of the bend is equal to the specified offset value.</p>	

* The bend width can have any positive values. Zero width is not allowed.

** Indent values can be both positive and negative. When calculating the bend width, indent symbols are taken into account: positive indents are laid off inside relative to the part body, and negative ones— outside. Indent values which make the bend width negative or equal to zero, and also values which separate the bend from the part body, are not allowed.

*** An offset value can be either positive or negative. A positive offset is made inward with respect to the parts body, the negative— outward. Offset values that make the bend detached from the part's body are not allowed.

2.4.4.4.2. Bend Extension

A **bend extension** is a portion of the sheet body adjacent to the bend on the side opposite to the edge, along which this bend is positioned (Fig 2.4.32).

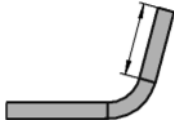

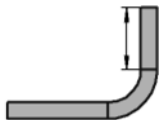

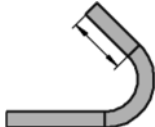

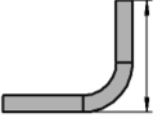

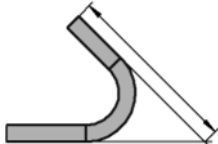

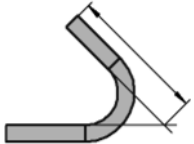

Fig. 2.4.32. Bend extension along the edge

Enter length of bend extension in field **Length**.

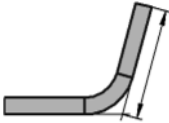

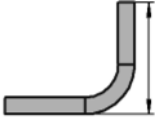

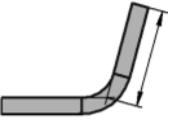

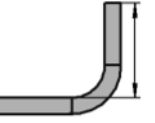

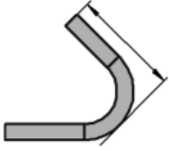

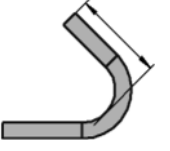

Indicate the method to set length for bend extension, selecting the right option from list **Method to set length** (Table 2.4.5). When using the methods **Length by contour** and **Length by Tangency**, the **Inside** option is available, that allows to select a surface limiting the extension length.

Tab. 2.4.5. Chart of defining length of bend extension*

Option value	Inside option is off	Inside option is on
Method to set length		
 Length		
		
 Length Along Contour		
		

Option **Inside** is not available when using method **Length**.

Tab. 2.4.5. Chart of defining length of bend extension*

Option value	Inside option is off	Inside option is on
Method to set length		
 Length by tangency		
		
		

* The scheme shows the part projection (mapping) on the plane perpendicular to the bend line.

Peculiarities to Set Parameters for Bend Extension

- ▼ When using the **Length** method, it is possible to enter the zero length. This means the bend will be created without an extension (Fig. 2.4.33).

Fig. 2.4.33. Examples of bends without extension

- ▼ When using the methods **Length by contour** and **Length by tangency**, the value entered in the **Length** field must be greater than a certain minimum value (Fig. 2.4.34). In a general case, it depends on the material thickness, angle and bend radius.

Fig. 2.4.34. Minimal length

- ▼ Defining **Length by contour** is possible for angles from 0° to 180°.

2.4.4.4.3. Bend Offset

Bend shift is a parameter characterizing the bend offset in the base face plane. The bend shift is made perpendicular to the edge, along which it is positioned.

To indicate the type of shift of a bend relative to the edge, select the right option from list **Shift Type**.

With shift when offsetting a bend inward or outward, the offset distance is defined by the user arbitrarily. The **Offset** field is provided to enter this distance. With zero shift the bend starts directly from the edge (Fig. 2.4.35, a), and with positive one— it moves inside or outside (Fig.2.4.35 b, c)

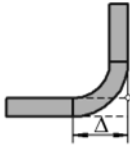

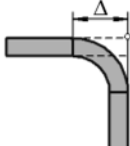

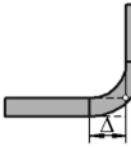

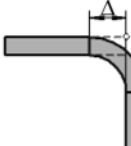

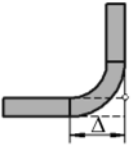

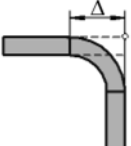

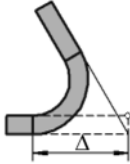

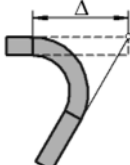

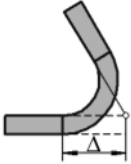

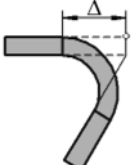

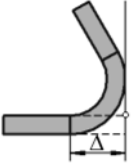

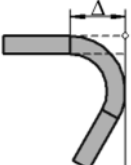

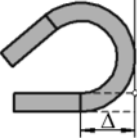

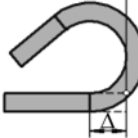

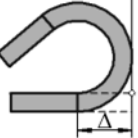

Fig. 2.4.35. Bend Offset a) zero, b) inward, c) outward

For other offset types, the offset distance is automatically determined by the system. This distance depends on the bend angle, material thickness and the inner radius of the bend (Table 2.4.6).

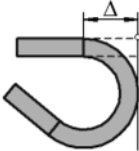

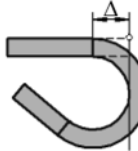

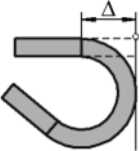

Tab. 2.4.6. Building chart and shift value*

Bend angle α	By external contour line	By internal contour line	Tangent to bend
from 0° to 90°			
	$\Delta = (r + s) \cdot \text{tg}(\alpha/2)$	$\Delta = r \cdot \text{tg}(\alpha/2)$	$\Delta = (r + s) \cdot \text{tg}(180 - \alpha/2)$

Tab. 2.4.6. Building chart and shift value*

Bend angle α	By external contour line	By internal contour line	Tangent to bend
			
90°	  $\Delta = r + s$	  $\Delta = r$	  $\Delta = r + s$
from 90° to 180°	  $\Delta = (r + s) \cdot \text{tg}(180 - \alpha/2)$	  $\Delta = r \cdot \text{tg}(180 - \alpha/2)$	  $\Delta = r + s$
more than 180°			

Tab. 2.4.6. Building chart and shift value*

Bend angle α	By external contour line	By internal contour line	Tangent to bend
			
			
	$\Delta = r + s$	$\Delta = r$	$\Delta = r + s$

* The chart indicates the model projection to a plane perpendicular to the edge, along which the bend is located. The edge projection is designated with a circle.

2.4.4.4.4. Lateral Sides

When creating a bend along the edge, two methods to manage parameters of lateral sides of the bend are possible:

- ▼ Change of width of bend extension (Fig. 2.4.36)

Fig. 2.4.36. Change in the bend extension width: a) increase, b) reduction

- ▼ Defining the bend angle and/or the slope of lateral sides on the bend extension (Fig. 2.4.37).

Fig. 2.4.37. Managing end sides of the bend
 a) angles at the bend, b) the slope of side faces of the extension,
 c), d) angles at the bend and the slope of side faces of the extension

To select a setup option for the left lateral side, activate the right switch **Slope and Angle** or **Extension** in group **To the Left**.

To select a setup option for the right lateral side, activate the right switch **Slope and Angle** or **Extension** in group **To the Right**.

Slope and Angle

Rules of defining the angle of a side wall slope and the angle at the bend:

- ▼ Angles are measured **on the unbent bend**.
- ▼ Angles are counted from the plane perpendicular to the edge, along which the bend is positioned.
- ▼ Angles can be in the range from -90° to $+90^\circ$.
- ▼ Positive angles are counted inward with respect to the bend body, the negative— outward.

To enter the inclination angle of the bend extension side wall use the **Slope** field.

To enter the bend angle, use the **Bend Angle** field.

If the bend angle is a nonzero, then the respective site face of the bend will not be planar.

Extension

Widening of bend extension is the change in the width of the bend extension as compared to the bend width.

The widening value can be negative, positive or zero. A negative widening means a reduction in the width of the bend extension, positive is an increase in the width of the bend extension, zero— no change in the width.

Use the **Extension** field to enter the value of the bend extension widening.

2.4.4.4.5. Bend Release

Release of bend is made by slots in the sheet part made on the sides of a bend.

Release can have a rectangular or round shape. Dimensions of release are defined by its depth and width (Fig. 2.4.38).

Fig. 2.4.38. Bend release: a) rectangular, b) rounded

To form release of bend, activate switch **Release of Bend** in the tab **Release** of the Properties panel.

To select shape of release, activate the right switch— **Rectangular** or **Round**— in group **Type**.

Enter the dimensions of the release in the fields **Depth** and **Width**. Values of depth and width can be zero or positive.

The option **Account for Bend Width** controls placement of releases with respect to a bend. If release widths are to be included into the bend width (in this case, the actual bend width decreases, see Fig. 2.4.39, b), activate this option. When the option is switched off, release widths are not included into the bend width (the bend width doesn't change, see Fig. 2.4.39, c).

Fig. 2.4.39. Location of releases: a) the bend width without releases, b) account for bend width in releases, c) don't account for bend width in releases

If the angle at the bend (see Section 2.4.4.4 on p. 269) is not equal to zero, release of bend rotates (Fig. 2.4.40). Rotation angle of release is equal to angle at the bend. In this case, the release depth is counted along the side face of the unbent bend, while the release width is perpendicular to that face (Fig. 2.4.41).

Fig. 2.4.40. Release of bend with angle at the bend not equal to zero

Fig. 2.4.41. Definition of dimensions for release of bend with angle at the bend not equal to zero

2.4.4.5. Bend by Line

You can bend a sheet body by straight line relative to some external or internal flat face of this part. The selected line and face will be considered the bend line and the base face of the bend.

To bend a sheet body by line, call command **Bend by Line**.

Indicate the basic face and the bend line (see Section 2.4.4.5.1).

Select the direction of count and angle interpretation (see Section 2.4.4.3.1 on p. 254).

- Indicate the value and the method of defining bend radius (see Section 2.4.4.3.2 on p. 256).
- Set up release of angle (see Section 2.4.4.3.3 on p. 256).
- Select the bend state (see Section 2.4.4.3.4 on p. 258).
- Set up the definition of the flat pattern length of the bend (see Section 2.4.4.3.5 on p. 259).

2.4.4.5.1. Original objects and construction result

The bend line should have the following parameters:

- ▼ Line segment of a sketch, constructed on outer or inner flat face of a sheet body,
- ▼ Straight edge of a geometry-creating feature or surface,
- ▼ polyline segment,
- ▼ Auxiliary axis.

Bend line requirements:

- ▼ The bend line must lie in the plane of the base face,
- ▼ The bend line should not coincide with the edge of the basic face.
- ▼ The bend line should cross or have a common point at least with one edge of the basic face (in the last case, extension of the bend line should cross the contour of the basic face, i.e., the common point should not be the contact point for the edge and the bend line).
- ▼ The bend line can be fully located inside the contour of the basic face (in this case, one or both end points of the bend line can be located at edges of the face).

The auxiliary axis is infinite. Therefore, when selecting an axis to be the bend line, it doesn't matter, if the section depicting this axis crosses the contour of the basic face or not (see Fig. 2.4.44).

The result of bend creation depends on the relative position of the base face and the bend line. A general rule is: the bend is performed for the part section that includes the basic face or a section of the basic face that crosses the bend line or its extension.

If a straight line segment or a polyline segment is used as a bend line, and the face being bent has a complex shape, then, for the bend to be constructed correctly, we recommend positioning the bend line in such a way as to explicitly go through all portions that are meant to be bent.

Fig. 2.4.42– 2.4.44 indicate options of bends for a sheet body, built using command **Bend by Line**. The upper flat face is used as the basic face in all the given cases; the bend line is displayed as thickened.

Fig. 2.4.42. Dependency of the resulting bend on the bend line position: a), c) options of position for the bend line, b), d) corresponding results of building

Fig. 2.4.43. Bending a part with a hole: a) position of the bend line, b) the result of building

Fig. 2.4.44. Using an auxiliary axis as the bend line:
a) location of the axis, b) the result of building

2.4.4.5.2. The Fixed Side of the Bend

When building a bend by line, the model window displays the phantom arrow (Fig. 2.4.45). It indicates the forward direction of count of the bend angle and its **fixed side**, the section of the basic face, the position of which will not change during the bend.

Fig. 2.4.45. Bend by line: a) direction and fixed side, b) the result of the operation

To make another side fixed, use the group of switches **Fixed Side**.

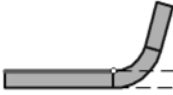

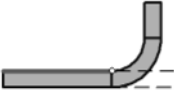

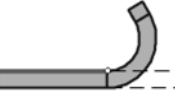

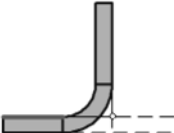

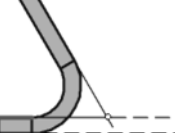

Change of the fixed side immediately affects the arrow position in the model window.

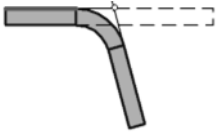

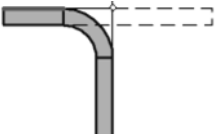

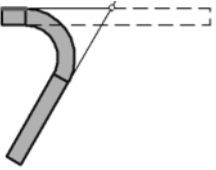

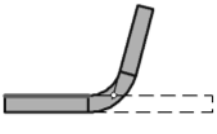

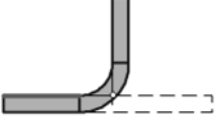

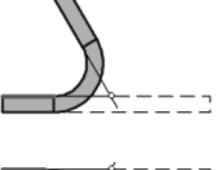

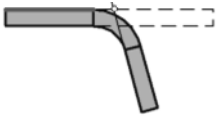

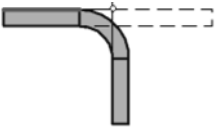

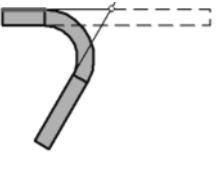

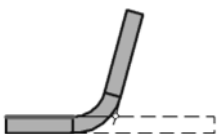

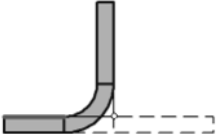

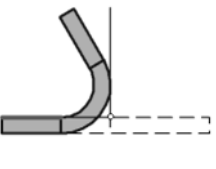

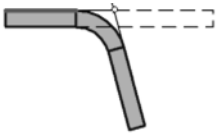

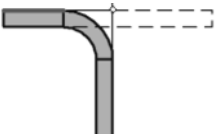

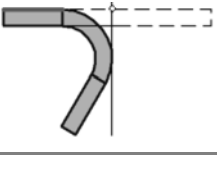

2.4.4.5.3. The Method to Form the Bend

When building a bend by line, you can select the method to form it from list **Bend Method** (Table 2.4.7). The table indicates the schemes to build bends for various values and directions of angle count.

Tab. 2.4.7. The scheme to build a bend, depending on the forming method*

Value of option	Scheme of creating		
Bend method			
 By Bend Line			
			
 Bend line outside			

Tab. 2.4.7. The scheme to build a bend, depending on the forming method*

Value of option Bend method	Scheme of creating			
	Bend line inside			
	Tangent			
				
				
				

* The scheme shows the part projection (mapping) on the plane perpendicular to the bend line. The base face protection is marked by a thickened line, and the bend line projection— by a circle.

2.4.4.6. Incision

Serves to create two straight-line bends at once in a part with respect to some face of the part. The selected line and face will be considered the bend line and the base face of the incision.

To build an incision, call command **Incision**.

Specify a base face of the release and a bend line (see Section 2.4.4.6.1).

Select the fixed side (see Section 2.4.4.5.2 on p. 274).

Select the direction of count and angle interpretation (see Section 2.4.4.3.1 on p. 254).

The value of the bend angle of the incision should be more than 0° and less than 180°; complementary angle— more than 0° and less than 360°.

Indicate the value and the method of defining bend radius (see Section 2.4.4.3.2 on p. 256).

Select the method to form the bend (see Section 2.4.4.5.3 on p. 275).

Set up release of angle (see Section 2.4.4.3.3 on p. 256).

Select the bend state (see Section 2.4.4.3.4 on p. 258).

Set up the definition of the flat pattern length of the bend (see Section 2.4.4.3.5 on p. 259).

The specified value and method of defining the radius, as well as the default method of defining flat pattern length — are used for both incision bends. Later on, you will be able to assign individual parameters to each of the bends (see Section 2.4.4.3.6 on p. 260).

2.4.4.6.1. Original objects and construction result

The following linear objects can be used as the bend line for incision:

- ▼ Line segment of a sketch, constructed on outer or inner flat face of a sheet body,
- ▼ polyline segment,
- ▼ auxiliary axis,
- ▼ Straight edge of a geometry-creating feature or surface.

Bend line requirements:

- ▼ The bend line must lie in the plane of the base face,
- ▼ The bend line must have at least one common point with the base face.

An auxiliary axis appears in the model as a straight line segment. Nevertheless, the axis is an infinite line. Therefore, when selecting an axis as the bend line, it doesn't matter whether the axis-denoting line segment has common end points with the base face. For a bend to be created correctly, it is sufficient that the axis projection (extension) has common points with the base face.

The result of incision creation depends on the relative position of the base face and the bend line. A general rule is: bending is done on the portion of the part including the base face or fraction thereof that fully or partially contains the bend line.

If a straight line segment or a polyline segment is used as a bend line, and the face being bent has a complex shape, then, for the bend to be constructed correctly, we recommend positioning the bend line in such a way as to explicitly go through all portions that are meant to be bent.

Fig. 2.4.46–2.4.49 indicate incision options. The upper flat face of the part is used as the basic face in all the given cases; the bend line is displayed as thickened.

Fig. 2.4.46. Dependency of the construction result on the bend line position:
a), c) options for position of the bend line,
b), d) corresponding results of performance of the operation

Fig. 2.4.47. Using an auxiliary axis as the bend line:
a) location of the axis, b) the result of building

Fig. 2.4.48. The use of the edge as the bend line of incision:
a) location of the edge, b) the result of building

Fig. 2.4.49. Incision in a part of the hole:
a) position of the bend line, b) the result of building

2.4.4.6.2. Incision Size

Using switches of group **Dimension**, select the option to set incision height:

▼ **External dimension of incision,**

▼ **Internal dimension of incision,**

▼ **Full dimension of incision.**

Enter the value for dimension of incision in filed **Distance**.

2.4.4.6.3. Incision With and Without Adding Material

Option **With the Use of Material** allows to indicate if it is necessary to build incision with adding of material or without adding of material.

Incisions with and without adding material, created using the same and lines and base face, differ in the following properties:

- ▼ Shape of the rectangular incision projection on the base face
- ▼ unbent incision shape.

As an example, let's review a release introduced in a feature shown on Fig 2.4.50.

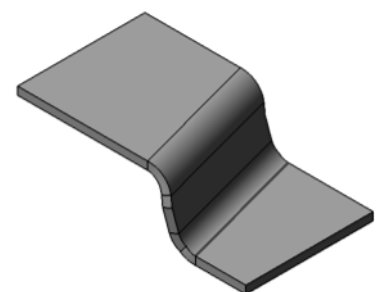

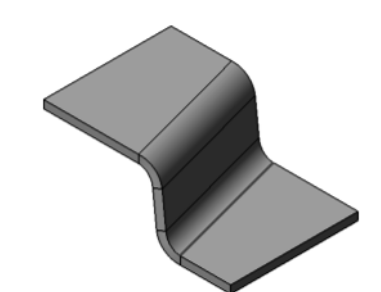

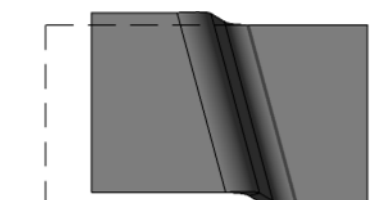

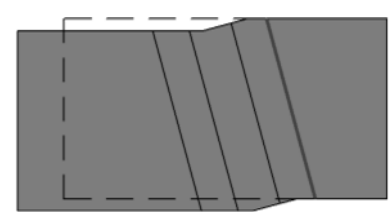

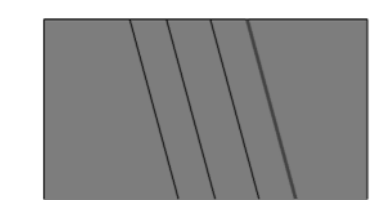

Fig. 2.4.50. The source incision element: a) isometric projection,
b) projection of the source element to the basic face

Comparison of results of incision building is given in Table 2.4.8.

Tab. 2.4.8. With and without adding material*

The differing properties are	Method of incision creation	
	With adding material	Without adding material
		
		
Incision projection on the base face	...coincides with mapped contour of the source element	...does not coincide with mapped contour of the source element
		
Unbent incision shape	...does not coincide with the shape of the source element	...coincides with the shape of the source element

* The bend line is shown as a thickened line, and projection of the source element— as a stroked one.

2.4.4.6.4. Flat Portion of the Incision

There can be a flat area between bends of the incision. Its presence depends on the proportion of preset (H) and minimal (H_{\min}) dimensions of incision (see Table 2.4.9).

H_{\min} — minimal internal dimension of incision without a flat area— is calculated using the formula:

$$H_{\min} = 2 \cdot R - (2 \cdot R + S) \cdot \cos \alpha, \text{ where}$$

R—internal radius of bends;
 S is the sheet metal thickness;
 α is the bend angle.

Tab. 2.4.9. Finding a flat portion in an incision*

Proportion between preset and minimal dimensions of the incision

$H > H_{\min}$

$H > H_{\min}$

$H = H_{\min}$

Incision with a flat area. Values of H, R and α parameters correspond to the preset ones.

Incision without a flat area — with bend. Values of H, R and α parameters correspond to the preset ones.

Incision without a flat area. The H and R parameters have a higher priority, therefore the value entered in the **Angle** field will be ignored. The bend angle value is calculated by the system automatically based on the above formula.

* The figures show projection of incision to a plane perpendicular to the bend line of this incision.

2.4.4.7. Cap Corners

Capping of angle is a modification of two adjacent bends and their extensions (Fig. 2.4.51).

Fig. 2.4.51. Capping of angle: a) original part status, b), c), d) options of capping of angle

Adjacent are the bends that have a common edge positioned as shown on Fig.2.4.52.

Fig. 2.4.52. Adjacent bends

Therefore, the bends with a release or those shifted with respect to each others are not considered adjacent (Fig. 2.4.53). Their respective corners cannot be capped.

Fig. 2.4.53. Examples of non-adjacent bends

The flat portions of the part that are modified by capping the corner are called the **sides** of the corner.

Radii, angles and lengths of extensions of adjacent bends should be pairwise equal to cap corners accurately.

Capping of angle is characterized by the following parameters:

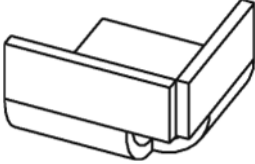

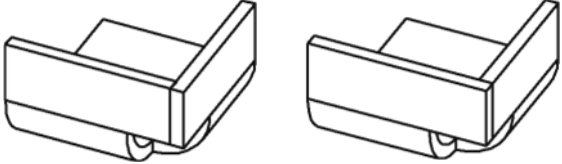

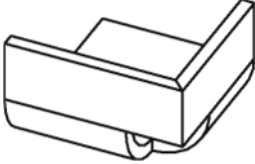

- ▼ Method (see Section 2.4.4.7.1),
- ▼ angle treatment (see Section 2.4.4.7.2),
- ▼ gap (see Section 2.4.4.7.3),
- ▼ extension (see Section 2.4.4.7.4).

The principle to perform capping of angle depends on the selected method. Building principles are described in Sections 2.4.4.7.5 and 2.4.4.7.6.

2.4.4.7.1. Methods of Capping

To indicate the capping method, open list **Type** on the tab **Parameters** of the Properties panel and select the right line from it (Table 2.4.10).

Tab. 2.4.10. Methods of capping of angle

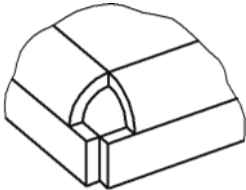

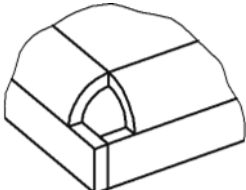

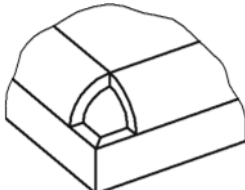

Value of option	Method	Construction result
	End-to-end closing	
	Capping with Overlap	
	Tight closing	

If you choose the **Capping with Overlap** option, a ghost arrow will be displayed in the Model window. It is located on the side of the angle that will overlap the second side. Click the **Change Overlapping** button to select another overlapping option. The arrow position will change in the Model Window.

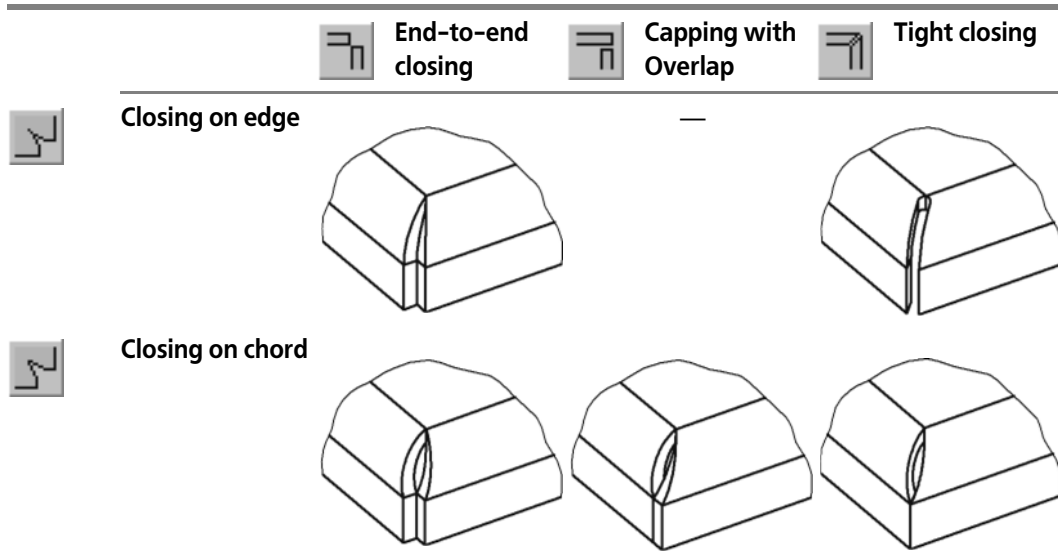

2.4.4.7.2. Angle Treatment

To indicate the angle treatment method while capping the angle, open list **Angle Treatment** and select the right line from it. Examples of corner treatment in connection with various capping methods are provided in the Table 2.4.11.

Tab. 2.4.11. Variants to process an angle using various methods during closing.

	 End-to-end closing	 Capping with Overlap	 Tight closing
 No ??processing			

Tab. 2.4.11. Variants to process an angle using various methods during closing.

Please note that the choices **Butt Juncture** and **Chord Juncture** are available if the adjacent bends have equal angles and equal radii. At the same time, the chord juncture is possible with all capping methods, whereas the butt juncture— only for the butt capping and tight capping.

If the **Tight Capping** is used with the **Butt Juncture** corner treatment, then the flat patterns of adjacent bends could overlap if the gap is zero or small. To avoid this, we recommend using such a gap which guarantees no overlapping.

2.4.4.7.3. Gap

Gap is the distance that will be maintained between two sides of a capped corner. The gap is measured in the part projection on the plane perpendicular to the corner sides. Such plane can be represented by any plane perpendicular to the intersection of outer or inner faces of the corner sides (Fig. 2.4.54, a). The **closable angle** is measured in the same plane (Fig. 2.4.54, b).

Fig. 2.4.54. Measurement of the gap: a) defining position of the measuring plane, b) part projection on the measuring plane (view by arrow); c) capping corners

To enter the gap value, field **Gap** in tab Parameters of the **Properties** panel is used.

2.4.4.7.4. Extension of Capping

Switch on option **Continue**, if it is required to cap matching bends, adjacent to sides of the closable angle.

To continue capping is possible if the following requirements are met:

- ▼ For adjacent bends:
 - ▼ Radii, angles and lengths of extensions of adjacent bends should be equal by pair.
- ▼ For abutting bends:
 - ▼ Bends have no offset and/or relief, and their radii and angles are equal by pair.
 - ▼ Bend placement on the edges is made in such a way that every bend begins from the edge vertex that is turned to the corner being capped.

Fig. 2.4.55. Bend capping: a) original part status, b) capping without extension, c) capping with extension

Extension of capping is made up to the first pair of adjacent bends that do not meet the requirements.

2.4.4.7.5. The Principle to Build Line-On-Line Capping and Tight Capping

Let's consider the principle to build line-on-line capping and tight capping, using the part shown in Fig. 2.4.56 as an example.

Fig. 2.4.56. Butt capping: a) original part status, b) the result of capping of angle (the gap is not equal to zero)

The position of corner sides is determined as follows.

1. The bisector of the corner being capped is created in the plane in which the gap is measured (Fig. 2.4.57, a).
2. From each side of the bisector at the distance equal to half of the gap value, parallel lines are drawn (Fig. 2.4.57, a).
3. The corner sides are projected (extended) until reaching the obtained lines (Fig. 2.4.57, b). In tight capping, the corner sides are additionally modified: their lateral faces become parallel to the bisector (Fig. 2.4.57, c).

Fig. 2.4.57. Definition of position of angle sides with line-on-line capping and tight capping

The minimum gap amount is 0, the maximum is determined as shown in Fig. 2.4.58.

Fig. 2.4.58. In butt capping

2.4.4.7.6. The Principle to Build Capping with Overlap

Capping with overlap is constructed differently, depending on what is the corner to be capped— acute or obtuse.

Let's consider the principle to build capping with overlap, using parts shown in Fig.2.4.59 as an example.

Fig. 2.4.59. Capping with overlap (original state of the part and the result of the operation):
a) closable acute angle, b) closable obtuse angle

The size of the corner being capped is affected by the relative position of the bends (the angle between the bend lines), and the angles of the bends themselves.

Capping with overlap is built as follows.

1. Straight line is constructed in the plane of measuring the gap—the trace of the outer face plane of the overlapped corner side (Fig. 2.4.60, a; 2.4.61, a).
2. The overlapping side is projected (extended) until it reaches that line (Fig. 2.4.60, b; 2.4.61, b).
3. The overlapped side is projected (extended) up until the distance between it and the overlapping side becomes equal to the specified gap.
 - 3.1. If the closable angle is acute, the gap is measured, as shown in Fig. 2.4.60, c.
 - 3.2. If the closable angle is obtuse, the gap is measured, as shown in Fig. 2.4.61, c.

Fig. 2.4.60. Building of capping with overlap for an acute angle: a), b) definition of position for the overlapping side, c) definition of position for the overlapped side

Fig. 2.4.61. Building of capping with overlap for an obtuse angle: a), b) definition of position for the overlapping side, c) definition of position for the overlapped side

The minimum gap amount is 0, the maximum is determined as shown in Fig. 2.4.62.

Fig. 2.4.62. In capping with overlap:
a) closable acute angle, b) closable obtuse angle

2.4.4.7.7. Performance of Capping

To cap one or several angles of the part, call command **Capping of Angles**.

Select a pair of adjacent bends. To do this, select the lateral face (or the edge that belongs to the lateral face) of one of them. The side faces of the selected adjacent bends and their extensions will be highlighted in the Model window (the sides of the corner being capped).

Select the capping method (see Section 2.4.4.7.1 on p. 282).

Select the angle treatment option (see Section 2.4.4.7.2 on p. 283).

Set the gap, which is used when capping the angle (see Section 2.4.4.7.3 on p. 284).

If necessary, switch on option **Continue** (see Section 2.4.4.7.4 on p. 285).

By calling the **Angle Closing** command once, you can select several angles for closing. Their list is displayed on the **Angles** bar (Fig. 2.4.63).

Closing parameters (method of closing, angle processing variant, gap and continuation) can be set up for each of the angles individually. For this purpose, select an angle in the **Angles** bar and set the required parameters.

Fig. 2.4.63.

To delete the highlighted angle from the list, activate switch **Delete**.

To delete the whole list, activate switch **Exclude All**.

Having finished with corner capping settings, click the **Create Object** button on the Advanced Control Panel.

The selected angles will be closed, and the Design Tree will display the image for capping of angles.

In some cases, adjacent bends have such parameters or are positioned in such a way relative to each other, that capping the corner becomes impossible (Fig. 2.4.64).

Fig. 2.4.64. Examples of adjacent bends, where the corner between them cannot be capped

2.4.4.8. Bend by sketch

Inside each sheet body you can create a bend by sketch— an element with several bends whose profile is determined by the sketch contour (Figure 2.4.65). The bend on the sketch is located along the straight edge (or several straight edges). This edge will be considered as the bend line and the edge containing it (external or internal)— base edge of the bend.

Fig. 2.4.65. ?Bend by sketch:
a) bend sketch, b) bend along one edge, c) bend along several edges

To build a bend on sketch, specify the sketch and call the **Bend on Sketch** command.

Select the bend construction method and specify an edge or a continuous sequence of edges, along which the newly created bend will be located (see Section 2.4.4.8.2).

Indicate the value and the method of defining bend radius (see Section 2.4.4.3.2 on p. 256).

Set up the definition of the flat pattern length of the bend (see Section 2.4.4.3.5 on p. 259).

Select the bend state (see Section 2.4.4.3.4 on p. 258).

Selected value and method of radius specifying as well as the broaching length definition method are used for all bends of the created element. Later on, you will be able to assign individual parameters to each of the bends (see Section 2.4.4.3.6 on p. 260).

2.4.4.8.1. Sketch Requirements

- ▼ The sketch shall be located in the plane perpendicular to the edge along which you will locate the bend.
- ▼ Sketch objects should comprise one contour.
- ▼ The Contour Must Be Open.
- ▼ The contour shall start from the point— the projection of the edge along which you will locate the bend.
- ▼ The sketch may consist of straight lines and circle's arcs only. The arcs must be connected with lines other arcs in tangent points.
- ▼ If the contour's first object is an arc, this arc shall be tangent to projection of the bend base face.

Similar to creating a sheet body by the open sketch, the contour corners form bends with user defined inner radius, and the arcs form bends with radii equal to those of the corresponding arcs.

2.4.4.8.2. Construction Method

Select creation type of bend by sketch using the **Method** group switch. The bend creation type determines bend width limits.

- ▼ If you select the **By Edge** bend creation type, the bend will be located along one edge. The bend width is equal to the edge length (Figure 2.4.66).

Fig. 2.4.66. Bend **By Edge**:
a) initial state of the model and the bend sketch, b) construction result

- ▼ If you select the **By length** creation type, the bend will be located along one edge as well. The bend width is user-defined and can be spread in any direction from the sketch plane (Figure 2.4.67). The corresponding direction of creation can be selected from the **Direction** list in the Property bar. This list offers the following options: **Direct Direction**, **Reverse Direction**, **Both Directions**, **Midplane**. The direct direction of creation is shown by the arrow on the bend ghost in the Model window. Width values to be input in the fields **Width 1** and/or **Width 2**.

Fig. 2.4.67. **By length** Bend:
a) in one direction from the sketch plane, b) in both directions

- ▼ If you select the **Chain of edges** creation type, the bend may be positioned along a chain of straight edges. All edges shall be specified as per their position order. Edges of a chain may be connected with each other through vertices (Figure 2.4.68, a) or bends (Figure 2.4.68, b).

Fig. 2.4.68. Bend along a chain of edges: a) vertex connected, b) bend connected

To make a bend along the edges connected with bends, specify not only straight edges, but also arc edges mating them.

2.4.4.8.3. Cap Corners

While creating a bend by sketch, you can setup corners capping using control elements of the **Cap Corners** tab on the Property bar (Figure 2.4.69).

Fig. 2.4.69. **Cap Corners** Tab

The **Cap Adjacent Corners** switch is available if you create a bend along a vertex connected edge chain. This switch allows to setup corner capping at the joints of chain edges (Figure 2.4.70): to select the capping method and the corner treatment and set a distance between the corner sides. The setup procedure is similar to the **Cap** command (see Sections 2.4.4.7.1–2.4.4.7.3), with the only exception that: the **Capping with Overlap** option is not available.

Fig. 2.4.70. Bend along a chain of edges:
a) with no corner capping, b) with capping (one of the options available)

The **Cap in the Start** and **Cap in the End** switches are available if you create a bend along one edge or an open chain of edges. These switches allow to shape the first and the last edges of the bend by sketch to ensure capping with the prospective adjacent bend (for example, to join with other parts). Since there are no adjacent bends for the first and the last edge, the capping is performed with respect to the plane α , which passes through the end point *A* of the bend (Figure 2.4.71, a).

To setup the plane α position, enter the angle value between this plane and the plane perpendicular to the bend line to **Angle 1** (or **Angle 2**) field. The angle value can be both positive and negative.

If required, input to the **Offset 1** (or **Offset 2**) field a distance at which the bend edge shall be located with respect to the plane α (Figure 2.4.71, b). The offset value can be only positive; the zero offset means that the bend edge is in the plane α .

Fig. 2.4.71. Bend with closing at the beginning and at the end:
a) A point and α plane, b) top view; indent and angle

The selection of capping method and corner treatment is similar to the case of the **Cap** command (see Sections 2.4.4.7.1 and 2.4.4.7.2), with the only exception that: the **Capping with Overlap** option is not available.

Constructing a bend on sketch is impossible if negative slope is specified for closing both the beginning and the end and **Without Processing** method of processing is selected.

Please note the following specifics of constructing a bend by sketch with capping along a chain of edges. If a chain contains edges that form face internal angle (Figure 2.4.72), construction is only possible if either the **Butt Junction** or the **Chord Junction** capping options are enabled. Therewith, if the internal angle is less than 90° , the capping will be created subject to the condition that the first element on the bend sketch is an arc (Figure 2.4.73). If the first sketch element is a line, the capping is impossible.

Fig. 2.4.72. Internal and external angles of the sheet body face

Fig. 2.4.73. Sketch starting from the arc

2.4.4.8.4. Release

When creating a bend by sketch, you can setup the bend and angle release parameters using the control elements on the **Release** tab of the Property bar (Figure 2.4.74).

Fig. 2.4.74. **Release** Tab

The **Bend Relief** switch is available, if either **By edge** or **By length** option is enabled. Activate this switch if you need to create slots on the bend sides. Once the switch is activated, the slot shape and size control elements become available. For more information about the bend relief, see Section 2.4.4.4.5 on p. 271.

If during creation of a bend by sketch you need to delete parts of neighboring bends, activate the **Release Angle** switch and select the respective relief method. For more information about the angle release methods, see Section 2.4.4.3.3 on p. 256.

The **Bend Proper** release option can be used for deleting bend portions which connect edges of the chain (Figure 2.4.75).

Fig. 2.4.75. Bend along a chain of edges connected by bends:
a) without angle release, b) with angle release

2.4.5. Plates

Plate is a flat boss feature attached to a sheet body. A plate is created by extruding a closed sketch. The extrusion depth can be arbitrary or equal to the body material thickness.

Before adding a plate to a sheet body, you need to create a sketch in the model, that determines the shape of the plate.

2.4.5.1. Plate Sketch Requirements

- ▼ Sketch must be constructed either on the outer or on the inner flat face of the sheet body only.
- ▼ Sketch objects can be a part of one or several contours.
- ▼ Contours must be closed.
- ▼ Contours can be nested. The number of nesting levels is one.
- ▼ The outer contour must intersect with the base face contour or have common points with it.

2.4.5.2. Forming of a Plate

To build a plate, call command **Plate**.

The **Plate** command is available, if at least one sketch is selected.

The model window will display the ghost image of the created plate. The arrow shows the extrusion direction. This direction is determined by the system automatically.

The **Thickness Object** list on the **Settings** tab (Property bar) makes it possible to specify whether the plate thickness is equal to the sheet body current thickness or a user-defined constant value.

Drop down the **Thickness Object** list to select the required sheet body. Thickness of the selected body will be displayed in the **Thickness** reference field.

To specify an arbitrary plate thickness, select **Without Object** line in the **Thickness Object** list. Field **Thickness** becomes editable. Enter the desired value there.

To confirm plate creation in the sheet body, click the **Create Object** button on the Advanced Control Panel.

The model window will display the created plate, and the Design Tree the corresponding image.

Fig. 2.4.76. Creation of a plate:
a) original state of the part and the sketch of the plate, b) operation result

If the plate fully or partially overlaps a bend, then its unbending becomes impossible. You can find more information on this in Section 2.4.7.3 on p. 307.

2.4.6. Holes

In a sheet body it is possible to create round holes and holes of a random profile— **cuts**.

To form round holes and cuts, you can use commands **Hole in Sheet Body** and **Cut in Sheet Body**, respectively. The detailed description of these commands is given in Sections 2.4.6.1 and 2.4.6.2.

To create holes in a sheet body, it is recommended to use exactly the **Hole in Sheet Body** and **Cut in Sheet Body** commands, as they take into account peculiarities typical for sheet bodies.

Cuts and holes can separate a sheet body into several parts (for more information about bodies consisting of several parts, see Section 2.3.11 on p. 224).

In each sheet body, which consists of several parts, it is impossible to create new and change existing bends, bends capping and create holes and cuts using the **Through** option. To make these operations possible, shape a body as a single piece; to do this, edit existing elements or create new elements to join all parts.

2.4.6.1. Hole

To create a round hole in a sheet body, highlight the face at which it will be located, and call command **Hole in Sheet Body**.

The model window will display the hole ghost.

By default, the hole center is positioned at the origin of the selected face's local coordinate system.

To position hole at the desired place on the face, enter the coordinates in the **p** field on the **Options** tab of the Property Bar. You can also select the hole position by the mouse. To do this, unfix the **p** field and select the desired point in the Model window. The selected point coordinates will be determined automatically.

Enter the hole diameter in field **Diameter**.

To set the hole position and diameter, handles can be used (see Section 2.1.4.2.2).

All changes are immediately reflected on the ghost of the hole in the Model window.

In group **Type** activate the switch that corresponds to the right type of building (see Table 2.4.12).

Tab. 2.4.12. Type of hole construction

Value of option	Building rules
Building type	
 By width	<p>The hole goes from the indicated face up to the opposite one in the direction, perpendicular to these faces.</p> <p>If a hole expands on a bend, possibly together with the adjacent part elements, then it wraps around this bend and the adjacent elements. You can create a hole using this method, if the following conditions are satisfied:</p> <ul style="list-style-type: none"> ▼ an outer or an inner flat face of the sheet body shall be specified for the hole construction, ▼ the hole should cross the specified face. <p>The Thickness Object list on the Parameters page of the Property Bar allows to specify whether the hole depth will coincide with the current thickness of a sheet body or will be equal to a constant value defined by the user.</p> <p>Drop down the Thickness Object list to select the required sheet body. Thickness of the selected body will be displayed in the Thickness reference field.</p> <p>If it is required to define an arbitrary thickness, select Without Object string in the Thickness Object list. Field Thickness becomes editable. Enter the desired value there.</p>
 By depth*	<p>Building of a hole by this method is cutting of the extrusion element with setting of a random extrusion distance. Extrusion is made perpendicular to the face selected for making a hole. The extrusion direction is inward with respect to the sheet body.</p> <p>To define the extrusion distance, enter the value in the Depth field on the Settings tab of the Property Bar.</p> <p>If the hole contacts the bend, it is not shifted to it, like “wrapping”.</p>

Tab. 2.4.12. Type of hole construction

Value of option	Building rules
Building type	
	<p data-bbox="372 287 501 318">Up to face*</p> <p data-bbox="601 287 1310 444">Creating a hole or cut by the 'Up to face' method amounts to cutting an extrusion feature with specifying an object for automatic extrusion distance determination. Extrusion is made perpendicular to the face selected for making a hole. The extrusion direction is inward with respect to the sheet body.</p> <p data-bbox="601 449 1310 542">To define an object to serve as an extrusion bound, select it in the Model window. This object can be represented by a face, surface, a projection or auxiliary plane.</p> <p data-bbox="601 547 1268 578">If the hole contacts the bend, it is not shifted to it, like "wrapping".</p>
<p data-bbox="355 626 1315 680">* If the file of the model, which is being edited, contains several sheet bodies, specify a sheet body in which this hole will be created. To specify the body, click it with the mouse in the model window.</p> <p data-bbox="372 686 1143 711">To change a sheet body, use the Specify Other button on the Special Control Panel.</p>	
 	<p data-bbox="372 760 1272 791">To confirm hole creation, click the Create Object button on the Advanced Control Panel.</p> <p data-bbox="372 797 1139 829">A round hole will be created in the part, and its icon in the Design Tree icon.</p>
	<p data-bbox="372 888 1315 942">Upon creating a hole in a part, a sketch is created automatically. It is located on the face, selected to construct a hole, and contains a construction point located on the hole axis.</p>

If a hole expands on the bend, then the hole will be rebuilt upon changes in the bend state (see Section 2.4.7.1 on p. 302). The resulting shape of the hole depends on its creation type and on what was the bend state at the time of creating the hole.

Let's consider examples of building and rebuilding of holes that contact bends, using the part shown in Fig. 2.4.77 as an example.

Fig. 2.4.77. Original part state. The centers of the would-be holes (positioned on invisible faces) are marked by "crosses"

Rebuilding of holes built **Through** is shown in Fig. 2.4.78.

Fig. 2.4.78. Holes created by the **Through** method
a) the part view immediately after creation of holes, b) the result of changes in state of bends

Rebuilding of holes built **To depth** is shown in Fig. 2.4.79. Holes built **Up to face** are re-built in a similar way.

Fig. 2.4.79. Holes built by method **By depth**:
a) the part view immediately after creation of holes, b) the result of changes in state of bends

2.4.6.2. Cut

Before forming of a cut in a part, it is necessary to create at its face a sketch that depicts the profile of this cut.

2.4.6.2.1. Requirements to the Sketch

- ▼ Sketch objects can be a part of one or several contours.
- ▼ Contours must be closed.
- ▼ The sketch must be constructed either on the outer or on the inner flat face of the sheet body only (for the construction of cut by the **Through** method).

2.4.6.2.2. Forming of a Cut

Call command **Cut in sheet body**.

The **Cut** command is available, if at least one sketch (cut sketch) is selected.

The part window will display the cut ghost.

Select type of cut construction. In group **Type** in tab **Parameters** of the Properties panel activate the switch that corresponds to the right building type. Building rules for cuts are the same, as for holes (see Table 2.4.12 on p. 296).

Indicate the part section that is to be cut off during excision. To do this, activate the right switch in group **Operation Result** in tab **Excision**.

If switch **Subtraction of Element** is active, the part section located inside the surface formed by shift of the sketch of the cut, will be deleted (Fig. 2.4.80,b).

If switch **Intersection of Elements** is active, the part section located outside this surface, will be deleted (Fig. 2.4.80,c).

Fig. 2.4.80. The result of building of a cut in a sheet body:
a) original state of the part and the sketch of the cut, b) the cut by subtraction, c) the cut by intersection

To confirm cut creation, click the **Create Object** button on the Advanced Control Panel.

A cut will appear in the part, and its image will be displayed in the Design Tree.

If a cut expands on the bend, then the cut will be rebuilt upon changes in the bend state (see Section 2.4.7.1 on p. 302). The resulting shape of the cut depends on its creation type and on what was the bend state at the time of creating the cut.

Let's consider options of building and rebuilding of cuts that contact bends, using the part shown in Fig. 2.4.81 as an example.

Fig. 2.4.81. Original part state. Sketches of cuts (located on invisible faces) are shown by the normal dashed line

Rebuilding of cuts built **Through** is shown in Fig. 2.4.82.

Fig. 2.4.82. Cuts created by the **Through** method:
a) the part view immediately after creation of cuts, b) the result of changes in state of bends

Rebuilding of cuts built **By depth** is shown in Fig. 2.4.83. Cuts built **Up to face**, are rebuilt in a similar way.

Fig. 2.4.83. Cuts built by method **By depth**:
a) the part view immediately after creation of cuts, b) the result of changes in state of bends

2.4.7. Unbending and Bending Bends. Flat pattern

Any bend (created using commands **Bend**, **Bend by Line**, **Bend by Sketch**, **Incision**, or during creation of a sheet body based on the open sketch) can be in a bent or unbent state.

By default, bends are formed in a folded state. If necessary, during creation (editing) of a bend or a sheet body it can be assigned the attribute “unbent”. This attribute can also be managed using commands **Unbend** and **Bend** in the context menu of the element (see Section 2.4.4.3.4 on p. 258).

Besides, special commands exist to change state of one or even several bends of a sheet body: **Unbend** and **Bend**.

Unbend command can be applied to bends without the “unbent” property, as well as to bends that were bent a by the **Bend** command.

Bend command can be applied to bends with the “unbent” property, as well as to bends that were unbent a by the **Unbend** command.

Working with the indicated commands is considered in detail in Section 2.4.7.1.

Assignment of the attribute “unbent” to a sheet body with several bends (for example, to an incision) means unbending of all its bends, while the **Unbend** command makes it possible to unbend bends selectively.

The described methods to manage state of bends can be applied at any time when editing the part. However, their impacts are not equal.

The difference between commands **Unbend** and **Bend** from the context menu of the sheet element and commands **Unbend** and **Bend** from menu **Operations— Features of Sheet Body** consists in the following.

The use of the first couple of commands is editing of a **separate element**: changed are the states of bends belonging to this feature, where as using the second pair means editing a whole sheet body: it gets an additional operation *Unbend* or *Bend*.

Like any other editing, sheet feature editing by the commands **Unbend** and **Bend** from the context menu could lead to **errors in objects dependent on these features** (holes, cuts, etc.).

Editing sheet elements by the **Unbend** and **Bend** commands from the menu **Operations— Features of Sheet Body** apparently cannot cause errors. Such editing, however, leads to a greater number of operations in the model and, therefore, the processing time (opening the file, rebuilding the model, creating associative views, etc.).

Therefore, if a bend does not have dependent objects (which can be checked, for example, by the command **Relations**), then its state can be changed by the context menu commands. In that case, you can better use the commands from the menu **Operations— Features of Sheet Body**.

If you know that certain bends need to be unbent to create some features, than the following work order can be preferred.

1. Create sheet features in the unbent state.
2. Create their dependent objects.
3. Bend the bends by the command **Operations— Features of Sheet Body— Bend**.

The described strategy allows avoiding an additional unbending operation.

Apart from the above-mentioned methods to change state of bends, there exists a special method to display a sheet body— **presentation in extended form**. In this mode, the bends selected by the user are shown in the bend state, while the rest are shown unbent.

States of bends set while editing the part, are ignored while switching to the extended display mode.

In the flat pattern mode you can view the part or measure its geometrical and mass-inertia properties. Editing of a part in the flat pattern mode is impossible.

Setup and activation of the mode to display the part in extended form are considered in Section 2.4.7.2 on p. 304.

2.4.7.1. Unbending and bending

To unbend or bend a bend (several bends) of a sheet body, call command **Unbend** or **Bend**, correspondingly.

After calling the command, you need to specify a **Plane of Bending/Unbending** and the **bends**, whose state needs to be changed. To do this, use the items provided on the **Options** tab of the Property Bar.

You can find more information on the purpose of elements and work with them in Sections 2.4.7.1.1 and 2.4.7.1.2.

Having finished with bend or unbend settings, click the **Create Object** button on the Advanced Control Panel.

A sheet body will be rebuilt in accordance with the preset unbending or bending parameters, while the Design Tree will display an image for unbending or bending.

2.4.7.1.1. Fixed face or plane

As a result of unbending or bending of any bend, the portion of the parts adjacent to that bend on one side is rotated with respect to the portion adjacent to the bend on the other side. In other words, one portion of the part stays still with respect to its coordinate system, while the other one moves.

When unbending/bending, you need to specify the fixed face or plane.

The fixed face is any planar face of a sheet body that belongs to its portion that stays still as a result of unbending or bending a bend (bends).

Dependence of the result of the operation on selection of the fixed face is shown in Fig. 2.4.84, using unbending of a bend as an example.

Fig. 2.4.84. Dependence of the result of unbending on selection of the bending plane:
a) original state of the part, b) face A is a plane of unbending, c) face B is a plane of unbending

Fixed plane is an auxiliary plane tangent to the bend which, when bending or unbending, will remain fixed and where the unbent bend (bends) will be located.

Objects that can be selected for setting the fixed plane:

- ▼ The bend's edge (cylindrical, conical)— external edge of the bend is specified. Auxiliary plane is created automatically and located at one of vertices of the face (Fig.2.4.85)
- ▼ The auxiliary plane tangent to the bend's edge (cylindrical, conical) of the sheet body.

The auxiliary plane with the required position may be created by the user in advance using commands **Tangent plane** or **Plane tangent to the edge in the point** on the **Auxiliary geometry** bar.

Fig. 2.4.85. Unbending of a sheet body:
a) initial state of a part, b) the result of unbending of the bend (when selecting a bend 1)

To specify the fixed face or plane, enable the **Plane** switch and select the required object in the model window.

When unbending a body, once the bending face has been specified, the automatically created auxiliary lane appears in the model.

If an auxiliary plane had been used for unbending, to put the body in the initial (bent) state, specify this plane as a fixed one using command **Bend**.

The selected plane will be highlighted in the Model window and in the Design Tree. The selected face will be highlighted in the Model Window, while the element it belongs to will be highlighted in the Design Tree.

2.4.7.1.2. Selection of Bends

To proceed with selecting bends, whose state needs to be changed, activate the switch **Select Bends**.

- ▼ To use the unbending command, you need to select the bent bends. To select a bent bend, pick any of its cylindrical faces in the Model window.
- ▼ To use the bending command, you need to select the unbent bends. To select an unbent bend, pick any its flat face that is supposed to become cylindrical, in the Model window.

If a model contains several sheet bodies, only the bends which belong to the same body as the auxiliary plane or the face indicated as the fixed one will be available.

The model window will display the selected bends as highlighted, and the Design Tree will show bends and sheet elements, to which they belong.

The list of bends indicated for unbending (bending), is displayed in panel **Bends** (Fig. 2.4.86). This panel also contains buttons to manage the list of bends. The functions of the buttons are represented in Table 2.4.13.

Fig. 2.4.86.

Tab. 2.4.13. Management of the list of bends

The	Description
	<p>Select all</p> <p>Allows selecting all bends.</p> <p>When working with the unbending command, all ‘bent’ bends are included in the list, while when working with the bending command—all ‘unbent’ ones are included.</p> <p>After the button is pressed, the selected bends are highlighted in the model window and in the Design Tree.</p>
	<p>Delete</p> <p>Allows excluding a selected bend from the list.</p> <p>Upon clicking the button, the selected bend becomes dehighlighted in the Model Window.</p> <p>Selecting a selected bend in the Model Window results in excluding it from the list.</p>
	<p>Exclude All</p> <p>Clears the list of bends.</p> <p>Upon clicking the button, all bends become dehighlighted in the Model Window.</p>

2.4.7.2. Flat pattern

Before switching to the mode of displaying the flattened sheet body, you need to set up the **flat pattern parameters**— select the fixed face or plane and define bend states (see Section 2.4.7.2.1).

Having finished setup of flat pattern parameters, save parameters by pressing button **Create Object** in the Advanced Control Panel.

To switch to the extended display mode, call command **Flat Pattern**. The current model will be displayed according to its stored flat pattern parameters.

For the convenience of viewing the flat pattern of the part, you can use the **Flat Pattern** orientation (see Section 2.4.7.2.2 on p. 306).

To switch to the normal mode of working with the sheet body, call the command **Flat Pattern** again.

2.4.7.2.1. Flat Pattern Parameters

To set flat pattern parameters, call command **Flat Pattern Parameters**. The Property Bar will display controls for setting up a flat pattern (Fig. 2.4.87).

Fig. 2.4.87. Flat pattern parameters control elements

- ▼ If a model contains several sheet bodies, flat pattern parameters shall be setup for each body. To setup the body flat pattern parameters, select this body in the body list and specify its fixed face or plane and unbent bends.
- ▼ If a model contains only one sheet body, there is no need to select it; select directly the fixed face or plane and bends.

Selection of Bodies

To select a body, specify it in the list on the **Bodies** bar (Figure2.4.87). The selected body will be highlighted in the Model window.

The list lines are displayed in different colors:

- ▼ the line of a body for which unfold settings have not been defined yet has read color,
- ▼ the line of a body for which unfold settings have already been defined has green color.

There is no need to define settings for all bodies, you can setup one or several bodies.

Selection of the fixed face or plane

Selection of the fixed face or plane is performed in the same way, as when working with bending and unbending commands (see Section2.4.7.1.1 on p. 302).

Faces that do not belong to the sheet body or the planes not related to the body, whose flat pattern parameters are being setup at the moment, are unavailable for selection.

Bends Selection

To define the states of bends, in which the latter will stay through the flat pattern mode, activate the switch **Select Bends**.

After that the panel will become available (Fig.2.4.87), that contains the list of all the bends existing in the current part.

Options are displayed to the left from the bend names. Bends with enabled options will be displayed as unbent in the flat pattern mode, and bends with disabled options — bended. To cancel the bend, enable the option near its name. When selecting a bend in the list, it is highlighted in the Model Window, and upon selecting it in the Model Window— is highlighted in the list. This helps control correctness of settings.

Bends that do not belong to the sheet body, whose flat pattern parameters are being setup at the moment, can not be specified.

To speed up the setup, use the buttons located above the list of bends. The description of buttons is given in Table 2.4.14.

Tab. 2.4.14. Managing bend states

	The	Description
	Bend all	Serves to disable options of all bends.
	Unbend all	Serves to enable options of all bends from the list.
	Bend selected	It allows to disable options of the selected bends*.
	Unbend selected	Serves to enable options of the bends selected in the list*.

* To select multiple bends in the list, use the keys *<Shift>* and *<Ctrl>*.
To select multiple bends in the Model Window, simply select them one after another.

Face or plane Selection for Flat Pattern Orientation

By default, the **Flat Pattern** orientation (see Section 2.4.7.2.2) is set in such a way that the gaze direction is perpendicular to the selected fixed face or plane (if there are several bodies, to the fixed face or plane of the body, whose flat pattern parameters were setup first).

If required, you may select any other face or plane for the **Flat Pattern** orientation. To do this, activate the **View** tab of the Property bar and then select the required face or plane in the Model window. The face will be highlighted, while its name will appear in the **View's Plane** field.

2.4.7.2.2. Flat Pattern Orientation

When flat pattern parameters are set, the **Flat pattern** orientation is added for the current model's list of orientations (see Section 2.1.3.2 on p. 121).

Fig. 2.4.88. **Flat Pattern** orientation in the list of orientations

In the **Flat Pattern** orientation, the model shall be positioned in such a way that the gaze direction is perpendicular to the face or auxiliary plane specified as the view's plane when setting the flat pattern parameters (see Section 2.4.7.2.1).

2.4.7.2.3. Deleting Flat Pattern Parameters

To delete flat pattern parameters, call the command **Operations— Features of Sheet Body— Delete Flat Pattern Parameters**. The earlier defined parameters of the flat pattern and **Flat Pattern** orientation will be removed from the current model.

If the sheet body flat pattern parameters in the current model have not yet been set up, then those cannot be deleted. In this case, command **Operations— Features of sheet body— Delete Flat Pattern Parameters** is not available.

2.4.7.3. Peculiarities of Unbending and Bending

When unbending and bending bends using the **Unbend** and **Bend** commands, as well as when using the **Flat pattern** command, the following should be taken into account.

- ▼ If the bend is not involved with any other features, then its unbending and bending is always possible.
- ▼ Elements that contact the bend, can be located in such a way, that unbending or bending of this bend will prove to be impossible (Fig. 2.4.89, 2.4.90).

Fig. 2.4.89. Examples of sheet elements that make impossible unbending of the bend:
a) plate, b) hole, c) cut

Fig. 2.4.90. Examples of shape-generating and construction elements of a part,
that make impossible unbending of the bend:
a) glued and cut out elements, b) reinforcement plate, c) facet

- ▼ The operations, that result in bend edges or faces being totally rebuilt, always make its unbending or bending impossible (Fig. 2.4.91).

Fig. 2.4.91. Examples of operations that make impossible unbending of the bend:
a) casing, b) slope

- ▼ If a hole or cam contour cut expands on the bend cylindrical part and adjacent part of a sheet body, passing non-perpendicular to this flat face, unbending is not available.

Fig. 2.4.92. Example of holes and cuts that make impossible unbending of the bend

- a) Holes built by method **By depth**:
 b) Cuts built by method **Up to Face** (cut sketch on the upper flat face of the body is shown by the dashed line)

- ▼ If a sheet body comprises several parts (for example, if a body is divided by the cut operation), change of the bends state is not possible. To unbend or bend the bends, modify a body to make it a single piece by editing existing elements or creating new elements to join all parts.

2.4.7.4. Flat Pattern Drawing

Associative views of KOMPAS-3D drawings support creation of flat pattern images of sheet bodies according to flat pattern parameters, stored within those models.

A flat pattern image can be produced when creating the following associative views:

- ▼ Arbitrary View,
- ▼ Projection View,
- ▼ View in Arrow Direction.

This section is intended for users with experience in creation of associative types. Building of these types is not considered in detail in the given section. If you don't master methods of work with associative types, it is recommended to see Section 3.6 on p. 1205.

To generate a flat pattern image in the view being created, activate the **Flat Pattern** switch on the **Options** tab of the Property bar. It is accessible if the flat pattern parameters are set up in the model.

Management of drawing of lines of a bend is performed in tab **Lines** (see Section 3.6.1.3.2 on p. 1211). Bend lines can be drawn automatically **if the plane of this view projections is parallel to the flat faces produced when unbending bends.**

To correctly select the plane of the view projections containing the flat pattern, you need to know how the flattened part will be positioned with respect to the main projection planes. This position depends on what face of the body or plane was picked as the fixed one at the time of setting up the flat pattern.

Let's consider selection of a projection plane to display the flat pattern for a part shown in Fig. 2.4.93, a.

Fig. 2.4.93. Sheet Body: a) in projection **Isometric projection XYZ**, b) master view

Let's assume that the body master view (Fig. 2.4.93, b) has already been built in the drawing. It is necessary to create a flat pattern.

In such a case, it is helpful to create an arbitrary view of this model in the drawing.

When creating an arbitrary view, the line **Flat Pattern** becomes available in the **Orientation** list on the **Options** tab of the Property Bar (Fig. 2.4.94). Selecting it means having the plane of the view projections parallel to the face selected as the fixed one at the time of setting up the flat pattern of the model.

Fig. 2.4.94. **Flat pattern** in the list of model orientation on arbitrary view

If face A was set as the fixed face (see Fig. 2.4.93, a), to create an image of the flat pattern it is necessary to select orientation **Flat Pattern**.

If the fixed face was defined by Face B, then, to create the flat image, select the orientation **Top**, **Bottom** or **Flat Pattern**.

If the fixed face was set to Face C, then, to create the flat image, select the orientation **Top** or **Bottom**.

Switch on formatting, set up other view parameters, and then confirm its creation.

An arbitrary view containing the flat pattern image is automatically assigned a notation containing an “unbent” graphical symbol and a scale if the latter is different from the scale indicated in the title block.

Fig. 2.4.95. Flat pattern of a sheet body

You do not have to use the automatically generated **Flat pattern** orientation. If necessary, you can manually create the desired orientation in the model and use it when creating a flat pattern in the drawing.

When creating a View by Arrow or a Projection View, then you cannot select an orientation from the list, since the position of the projection planes of those views depends on the viewing direction. When selecting that direction, you need to take into account the position of the flattened part.

A sheet body is displayed on cut or section views in the same state as on the base view. When a part state is changed on that view (flattening being turned on or off), the cuts (sections) are rebuilt automatically.

2.4.8. Stamped Features

When creating a sheet body in KOMPAS-3D, it is possible to build the following stamp elements:

- ▼ Open and closed stamping (Fig. 2.4.96, a and 2.4.96, b)
- ▼ Beat (Fig. 2.4.96, c)
- ▼ Louver (Fig. 2.4.96, d).

Fig. 2.4.96. Stamped features

In fact, a drawn cutout creation is not a bending operation; rather, it is a deforming operation where the sheet material is stretched and its thickness reduced. When building stamp elements in a sheet body KOMPAS-3D, this change of material thickness is not counted.

It is impossible to unfold bends of stamp elements.

General methods to build stamp elements are described in Section 2.4.8.1, and special methods in Sections 2.4.8.2– 2.4.8.4.

To set parameters for stamp elements, handles can be used (see Section 2.1.4.2.2).

2.4.8.1. General Building Methods

After calling the command to build a stamp element, the Properties panel displays control elements that allow to set up various parameters of the element. The following parameters are common for all the stamp elements:

- ▼ Direction,
- ▼ Base rounding,
- ▼ Saving of settings.

2.4.8.1.1. Direction of building

The face of a sheet body that contains the sketch of a stamp element, is considered as the **basic face** of this element. No matter at which face— external or internal— the sketch is located, the stamp element based on it can be directed both inside of the part and outside of it (Fig. 2.4.97). In this case, thickness of sheet material is not counted, owing to which geometrical parameters of the element don't depend on the direction of building.

Fig. 2.4.97. The direction of building of a stamp element:
a) selection of direction, b) the result of building

The forward construction direction is the outward direction from the base face, the reversed one is inward. The current direction of creation is indicated on the screen by a ghost arrow.

To indicate the side of the basic face, at which the beat will be located, activate the right switch in group **Direction of Building**.

2.4.8.1.2. Rounding of Base Edges

Base of a stamped feature is a portion of a sheet body where the stamp feature is connected with its adjoining flat elements.

base edges are where side wall faces of a stamped feature meet the faces of its adjoining flat elements of the sheet body. In this case, the edges that belong to inner side faces of a dimple

or drawn cutout feature are considered **inner base edges** of the bend, while the ones that belong to the outer side faces are the **outer base edges** (Fig.

Fig. 2.4.98. Inner and outer base edges

Dimple or drawn cutout features can be created with base edge rounding or without rounding. To round base edges, enable the **Base Rounding** option and enter the rounding radius in the field **Radius of Base Round**. The specified radius value R is used to round outer edges of the base. The rounding radius of inner edges is equal to the sum $(R + S)$, where S is the thickness of the sheet material. The minimum value of base edge rounding radius is 0.

2.4.8.1.3. Saving of Settings

You can save the preset parameters for the stamp element for their further use when building similar elements up to the end of the work session. To do this, after completing element parameter setup, switch on option **By default**.

2.4.8.2. Stamping

The present section describes the procedure to build open and closed stamping. They have practically the same set of parameters and are created in a very similar way.

To build open stamping, call command **Open Stamping**.

To build closed stamping, call command **Closed Stamping**.

The commands to build stamping are available, if one sketch is highlighted— stamping profile (see Section 2.4.8.2.1).

Indicate the building direction (see Section 2.4.8.1.1 on p. 312).

Select the fixed side of stamping (see Section 2.4.8.2.2).

Set stamping height (see Section 2.4.8.2.3).

Set parameters for lateral walls (see Section 2.4.8.2.4).

Set parameters for edge rounding (see Sections 2.4.8.1.2 on p. 312, 2.4.8.2.5 and 2.4.8.2.6).

If a dimple is created with rounding bottom and/or base edges, then it is impossible to simultaneously satisfy the specified angle, radii and height values in the cases of small (relative to radii) heights of that dimple or drawn cutout. Since the height and the radius have a higher priority, the value entered in the **Angle** field will be ignored. The slope angle of side walls is calculated by the system automatically (this is, in fact, the inclination angle of lines tangent to side walls, since their planar portions become degenerate in these cases).

Having finished with settings, click the **Create Object** button on the Advanced Control bar to confirm the changes.

A new feature will be added to the sheet body being developed, and the respective icon will appear in the Design Tree:

▼ Open stamping,

▼ Closed stamping.

2.4.8.2.1. Stamping Profile

The **profile of a dimple or drawn cutout** is the shape of its bottom. The profile is defined by a sketch on which a dimple or drawn cutout is based. A thin-wall feature produced by extruding a sketch in the creation direction makes the side walls of a dimple or drawn cutout.

Requirements for the Sketch

- ▼ Sketch must be constructed either on the outer or on the inner flat face of the sheet body only.
- ▼ Sketch objects should comprise one contour.
- ▼ The contour can be closed or open.
- ▼ If the contour is closed, then it can intersect with the base face or fully belong to it.
- ▼ If the contour is open, then it must intersect the base face so as to have two common points with the edges that make up its outer contour. The end points of the contour may belong to those edges or be outside the base face.
- ▼ The common points of the contour and the base face shall not coincide with the vertices of the edges surrounding the base face.
- ▼ The contour shall not intersect or have common points with other body elements.

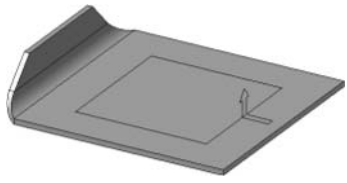

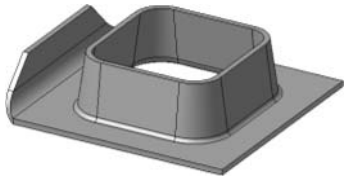

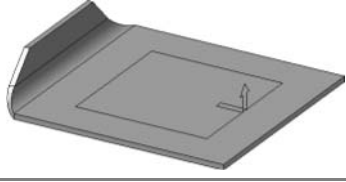

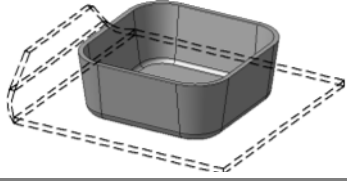

2.4.8.2.2. Fixed Side

Fixed side is the portion of the base face, whose position does not change when constructing a dimple or drawn cutout. The fixed side of a face may be inside the profile of a dimple or drawn cutout or outside it. The ghost arrow indicating the construction direction starts precisely at this location on the face.

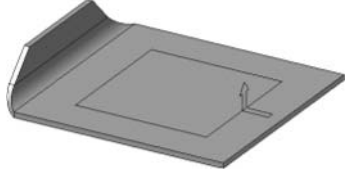

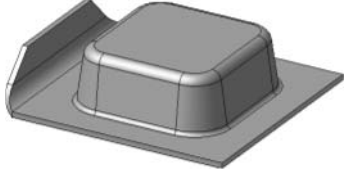

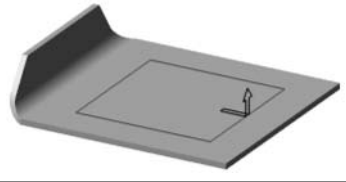

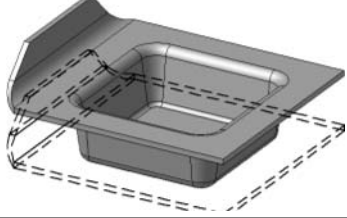

To change the fixed side, use the **Side** switch group. When changing the fixed side, the ghost arrow changes accordingly in the Model window.

Dependence of the result of building of open stamping on selection of the fixed side is given in Table 2.4.15, and closed stamping— in Table 2.4.16. A stroked line shows the original state of a part in figures. Note that closed stamping always has both a bottom and a base, while open stamping has either a bottom, or a base (depending on selection of the fixed side).

Tab. 2.4.15. Fixed side of a dimple

	Value of option Side	Original part state	The result of creation of stamping
	Side 1		
	Side 2		

Tab. 2.4.16. Fixed side of a dimple

	Value of option Side	Original part state	The result of creation of stamping
	Side 1		
	Side 2		

2.4.8.2.3. Height

To define stamping height, it is necessary to select the method to set stamping height and enter the height value.

When building open stamping, two methods to set height are available:

▼ **Full,**

▼ **Outside.**

When building closed stamping, three methods to set height are available:

▼ **Full,**

▼ **Inside,**

▼ **Outside.**

Select the method of defining the height, and then enter the desired value in the **Height** field.

When using the **Full** method, the specified value of the dimple height must be greater than the thickness of the sheet body.

2.4.8.2.4. Lateral Walls

When building stamping, you can manage the following parameters for lateral walls: direction to add material and slope.

Direction to add material

The width of a dimple or drawn cutout side walls can be counted inward or outward with respect to the surface swept by the profile moved in the creation direction.

To change the direction of adding side wall material, use the **Side Walls** switch group:

▼ For open stamping:

▼ **Inside**

▼ **Outside**

▼ For closed stamping:

▼ **Inside**

▼ **Outside**

Slope of Lateral Walls

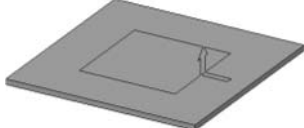

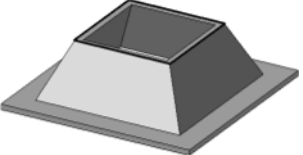

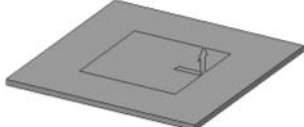

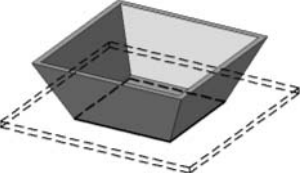

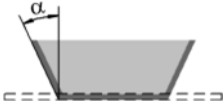

Lateral walls of stamping can be sloped in the direction of building. To build stamping with slope of lateral walls, enter the value for slope angle in field **Angle**. Zero value in this field stands for absence of slope.

The side walls inclination of a dimple or drawn cutout is made according to the following rules.

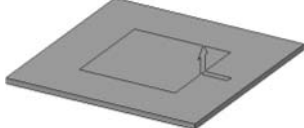

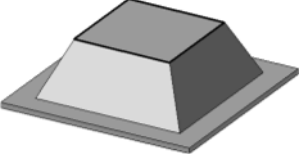

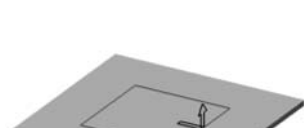

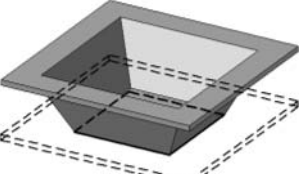

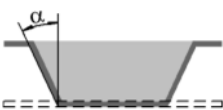

- ▼ The inclination angle is counted from the normal to the base face.
- ▼ The angle counting direction is selected such as to have side walls inclined inward with respect to the bottom of a closed stamping or open stamping.
- ▼ Original profile dimensions (defined by the sketch) are maintained near the bottom of a closed stamping or open stamping.

Examples to build open and closed stamping with slope of lateral walls are given in Tables 2.4.17 and 2.4.18, respectively. Direction to add material of lateral walls in all the examples—inside; α — draft of side walls; a stroked line indicates the original position of a part, while a thickened one shows the face that has preserved a shape and dimensions of the profile as a result of building.

Tab. 2.4.17. Open stamping side wall taper

	Original part state; Position of the fixed side	Construction result	Section by a plane perpendicular to the basic face
			
			

Tab. 2.4.18. Closed stamping side wall taper

	Original part state; Position of the fixed side	Construction result	Section by a plane perpendicular to the basic face
			
			

2.4.8.2.5. Rounding of Lateral Edges

Side edges are the edges at the joints of side wall faces of a dimple or drawn cutout. In this case, the edges that belong to inner side faces of a dimple or drawn cutout are considered **inner side edges** of the bend, while the ones that belong to the outer side faces are the **outer side edges** (Fig.2.4.99).

Fig. 2.4.99. Inner and outer side edges a dimple or drawn cutout

A dimple or drawn cutout can be created with or without side edge filleting.

To round side edges, enable the **Edge Round** option and enter the rounding radius in the **Radius** field. The specified radius value R is used to round inner side edges. The rounding radius of inner edges is equal to the sum $(R + S)$, where S is the thickness of the sheet material. The minimum radius value of side edge filleting is 0.

If lateral walls of stamping are sloped (see Section 2.4.8.2.4), R and $(R + S)$ are minimal radii of rounding for lateral edges. These radius values are maintained throughout the bottom of a dimple or drawn cutout. For example, the Fig.2.4.100 shows a drawn cutout with a slope on side walls and a round on side edges.

Fig. 2.4.100. A drawn cutout with a slope on side walls and a round on side edges: a) the rounding radius is equal zero, b) the rounding radius is greater than zero

The side edges of a dimple or drawn cutout, which are made by smoothly adjoining faces, are not rounded.

2.4.8.2.6. Rounding of Edges at the Bottom

Bottom edges are the ones where the dimple bottom faces meet its side wall faces. In this case, the edges that belong to inner side faces of a dimple or drawn cutout are considered **inner bend edges** of the bottom, while the ones that belong to the outer side faces are the **outer bend edges** of the bottom (Fig. 2.4.101).

Fig. 2.4.101. Inner and outer bottom edges of a dimple or drawn cutout (the sheet metal model is cut by a plane perpendicular to the base face)

A dimple or drawn cutout can be created with or without bottom edges filleting.

To round bottom edges, enable the **Bottom Rounding** option and enter the rounding radius in the **Bottom Rounding Radius** field. The specified radius value R is used to round inner edges of the bottom. The rounding radius of inner edges is equal to the sum $(R + S)$, where S is the thickness of the sheet material. The minimum value of bottom edge rounding radius is 0.

Open stamping can have either a bottom, or a base, depending on selection of the fixed side (see Table 2.4.15 on p. 315). Therefore, during its creation the Properties panel doesn't include control elements for rounding of the bottom or the base (see Section 2.4.8.1.2 on p. 312).

2.4.8.3. Beat

In a sheet body KOMPAS-3D a beat can be created with one of the three section shapes:

- ▼ Round (Fig. 2.4.102, a),
- ▼ U-shaped (Fig. 2.4.102, b),
- ▼ V-shaped (Fig. 2.4.102, c).

Fig. 2.4.102. Beat section shapes

Fig. 2.4.103.

To build a beat, call command **Beat**.

The command is available, if one sketch is highlighted—the beat sketch. The sketch defines the beat configuration and position. Requirements to the sketch are enumerated in Section 2.4.8.3.1.

A beat cannot be created if its sketch has common points with edges adjoining to bends.

Indicate the building direction (see Section 2.4.8.1.1 on p. 312).

Select beat section shape: **round**, **U-shaped** or **V-shape**.

Select beat ends processing type (see Section 2.4.8.3.2).

For convenience of work, panel **View** indicates a beat pattern (see Section 2.4.8.3.3).

Select the method to build a beat (see Section 2.4.8.3.4).

Enter beat parameters in the respective fields on the Property Bar. The set of these fields depends on the selected creation method.

Set up rounding parameters for edges at the base (see Section 2.4.8.1.2 on p. 312). For a U-shaped beat it is also possible to round edges at the bottom. This is done in the same way, as during creation of stamping see Section 2.4.8.2.6 on p. 318.

If, when creating a V-shaped or U-shaped beat with bottom and/or base edges rounding, a too small height is defined (compared to the radii), then it is impossible to simultaneously meet the values of the angle, radius (radii) and height. Since the height and the radius have a higher priority, the value entered in the **Angle** field will be ignored. The slope angle of side walls is calculated by the system automatically (this is, in fact, the inclination angle of lines tangent to side walls, since their planar portions become degenerate in these cases).

If the beat doesn't fit in completely within the basic face, it is cut by the plane (planes) of the corresponding end face (Fig. 2.4.104).

Fig. 2.4.104. The beat exceeding the limits of the basic face:
a) the beat sketch; b) the result of building

Having finished with settings, click the **Create Object** button on the Advanced Control bar to confirm the changes.

A new feature will be added to the sheet body being developed, and the respective icon will appear in the Design Tree:

2.4.8.3.1. Requirements to the Sketch

- ▼ Sketch must be constructed either on the outer or on the inner flat face of the sheet body only.
- ▼ Sketch objects can be a part of one or several contours.
- ▼ The contours can be closed or open.
- ▼ If a contour consists from several graphical objects, then those must smoothly adjoin to each other.
- ▼ Contours may intersect each other, but a contour self-intersection is not allowed.

2.4.8.3.2. Treatment of Ends

End of beat is a beat element corresponding to an end point with a contour in the sketch. The following options are available for treatment of ends:

- ▼ Closed (Fig. 2.4.105, a),
- ▼ Open (Fig. 2.4.105, b),
- ▼ Chopped (Fig. 2.4.105, c).

Fig. 2.4.105. Beat ends processing types

The selected type is applied to all ends of the current beat.

When selecting the **Chopped** processing type, a **Gap** field appears on the Property Bar, in which you need to enter the gap amount of chopping.

2.4.8.3.3. View Sample

The beat image is shown in panel **View**. There are two displaying options:

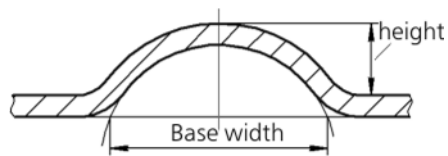

- ▼ A **side crosscut** with the dimensions corresponding to the section parameters,
- ▼ A **sample** — a schematic image of a rectangular beat that accounts for the selected section shape, ends processing type and base rounding.

To select the image type in panel **View**, option **Pattern** is used. If it is enabled, then the sample beat is displayed on the preview pane, if disabled— then it is the cut.

2.4.8.3.4. Construction Method

To select the method to build a beat, list **Method** is used. The set of methods available in this list, depends on the selected section shape (see Table 2.4.19–2.4.21).

Tab. 2.4.19. Method of creating a round beat

Method	Parameters
 By height and base width	

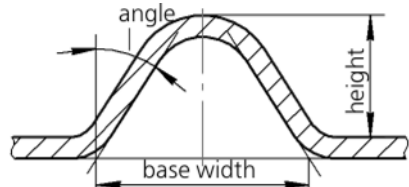

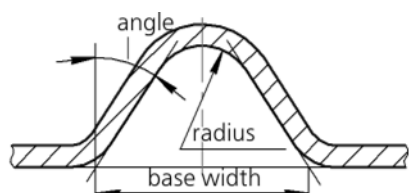

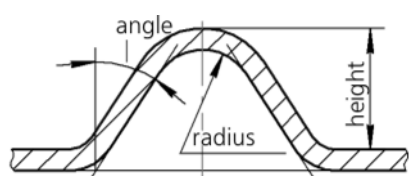

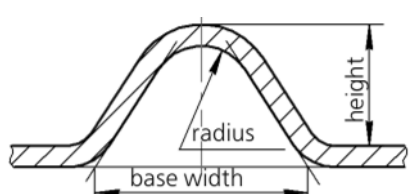

Tab. 2.4.19. Method of creating a round beat

Method	Parameters
A	By height and radius
D	By radius and base width

Tab. 2.4.20. Methods to build a U-shaped beat

Method	Parameters
D ₁	By height, angle and base width
D ₂	By width of the base, by height and width of the bottom
D ₃	By width of the base, by angle and width of the bottom
D ₄	By angle, height and bottom width

Tab. 2.4.21. Methods to build a V-shaped beat

	Method	Parameters
	By height, angle and base width	
	By height, angle and radius	
	By radius, angle and base width	
	By height, radius and base width	

2.4.8.4. Louver

Serves to create a louver by a straight line in a sheet body. Two louver types are available:

- ▼ Elongated (Fig. 2.4.106, a),
- ▼ Cut (Fig. 2.4.106, b).

Fig. 2.4.106. Louver types

To build a louver, call command **Louver**.

The command is available, if one sketch is highlighted— the louver sketch. Requirements to the sketch are enumerated in Section 2.4.8.4.1.

Indicate the building direction (see Section 2.4.8.1.1 on p. 312).

Select Louver position— to the right or to the left relative to the section in the sketch, activating the right switch in group **Position**.

Set the louver height (see Section 2.4.8.4.2).

Select the method to build a louver (see Section 2.4.8.4.4).

Set the louver width (see Section 2.4.8.4.4).

Set up rounding parameters for edges at the base (see Section 2.4.8.1.2 on p. 312).

Having finished setup, press button **Create Object** in the Advanced Control Panel to confirm creation of the louver.

A new element (elements) with the preset parameters will be added to the designed sheet body, while the Design Tree will display the corresponding image.

2.4.8.4.1. Requirements to the Sketch

- ▼ Sketch must be constructed either on the outer or on the inner flat face of the sheet body only.
- ▼ A sketch may contain a single line segment or several lines.
- ▼ The sketch should be fully located within the basic face (i.e., it should have no common points with edges that limit the basic face).
- ▼ The sketch segments may not intersect and/or have common points.

2.4.8.4.2. Height

To define the louver height, it is necessary to select the dimension type for the louver height and enter the height value.

Three types of height dimension are available:

- ▼ **Full,**

- ▼ **From face,**

- ▼ **Slot height.**

After selection of the dimension type enter the right value in field **Height**. The range of allowed height values of a louver depends on the thickness of the sheet material (S) and the width of the louver (B). This dependency is different for different types of the height dimension (see Table 2.4.22).

Tab. 2.4.22. The range of louver height values

	Height dimension type	Height value range
	Full	$S < H < B$, where H — full louver height

Tab. 2.4.22. The range of louver height values

Height dimension type	Height value range
 From face	$S < h < B - S$, where h is the louver height above the face
 Slot height	$0.00 < A < B - 2 \cdot S$, where A is height of the louver opening

Geometrical parameters of the louver are shown in Fig. 2.4.107.

Fig. 2.4.107. Geometrical parameters of the louver: a) elongated, b) cut with the end in trimming direction, c) cut with the end along the normal line to thickness

2.4.8.4.3. Width

To set the louver width, enter the right value in field **Width**. The width value B (see Fig. 2.4.107) should meet the following condition: $B > 2 \cdot S$, where S is thickness of sheet material. For a drawn louver, the width should also satisfy the condition $B < L/2$, where L — length of a line in the louver sketch.

2.4.8.4.4. Construction Method

To set the louver building method, expand list **Method** and select the right line from it. Two methods are available: **Drawn** and **Trim**.

When using method **Trim**, you can select the end shape:

▼ **In the direction of trim** or

▼ **By thickening normal**.

2.5. Points and curves

2.5.1. Theoretical Summary

This Section contains definitions and clarifications of some terms and notions for proper understanding of this part of the Manual.

2.5.1.1. Terms and Definitions

Connected Set of Faces— a set of faces each of which has at least one common edge with at least one face of the set whereas one edge simultaneously belongs to not more than two faces.

Connected set of curves (chain of curves) is a set of curves, each of which has a common vertex at least with one curve from this set, at that, any vertex can simultaneously belong to maximum two curves.

Single-Segment Curve—curve that consists of one part. Single-Segment Curve is always selected and involved in operations entirely. Single-Segment Curves examples: an arc, a spiral, a spline.

Multi-Segment Curve— a curve that consists (or potentially may consist) of several sequentially interconnected portions— segments. Multi-Segment Curve can be selected and involved in operations and entirely (to do this, you need to specify it in the model's Design Tree), and as individual segments (to do this, they should be specified in the model window). Multi-Segment Curves examples: Polyline, contour.

2.5.1.2. Parametric representation of the curve

In general, the model file describes a **curve** as a geometrical locus of points, with spatial coordinates of these points being functions of the t parameter:

$$x = x(t),$$

$$y = y(t),$$

$$z = z(t),$$

where parameter t is limited by threshold values $t_{\min} \leq t \leq t_{\max}$.

Such curve description is its **parametric representation**.

Parametric area of the curve is the range of the t parameter values represented as a line segment (see Fig. 2.5.1, a). The curve is the image of such line segment in the 3D model. Each point on the curved line corresponds to a specific t parameter value (see Fig. 2.5.1, b).

Fig. 2.5.1. Semi-cubical parabola (Neil parabola):
 a) parametric area of the curve – t parameter values;
 b) displaying t parameter values on a 3D curve

Note that generally the points evenly splitting the parametric area of the curve are displayed as points of the curve splitting it **unevenly**.

Let us consider parametric representation of the semicubic parabola (Neil parabola).

Curve Equation (or curve law):

$$y^2 = a^2 \cdot x^3, a > 0.$$

Parametric representation of the curve:

$$x = t^2,$$

$$y = a \cdot t^3,$$

$$z = 0,$$

$$-\infty < t < +\infty.$$

2.5.1.3. Parametric representation of the surface.

Isoparametric curves

The model file provides description of the **surface** as a geometrical location of points with spatial coordinates being determined by functions with reference to parameters U and V :

$$x = x(U; V),$$

$$y = y(U; V),$$

$$z = z(U; V),$$

where parameters U and V are bound by threshold values $U_{\min} \leq U \leq U_{\max}$, $V_{\min} \leq V \leq V_{\max}$.

Such surface description is its **parametric representation**.

Parametric area of the surface is the range of the U and V parameters, represented as a flat square area. The Surface is the image of such area in the 3D model. Each pair of U and V parameters' values have a related point on the surface.

If a value of either U or V parameter is fixed and another is changed, a surface curved line will be obtained. This curved line is called '**isoparametric**'. The curves produced by changing parameter U with parameter V fixed are considered isoparametric curves of direction U whereas the curves produced by changing parameter V with parameter U fixed are isoparametric curves of direction V . The curves of the both directions form the **isoparametric grid** enabling visual-

ization of the **theoretical** surface equivalent to the edge on the screen. Generally, there displayed five curves in each direction; the displayed curves correspond to 0, 25, 50, 75, 100 of U or V (Fig. 2.5.2). For example, an isoparametric grid is displayed when creating a point by the **On surface** method.

Borders of the theoretical surface may not necessarily coincide with the face contour, however, the face always lies within its theoretical surface borders. More over, unlike the face, the theoretical surface has no holes.

Fig. 2.5.2. Isoparametric grid example

2.5.1.4. Spline curves and surfaces Order of Curves. point weight

Spline curves and surfaces created using non-uniform rational B-splines (NURBS) are defined by the following parameters: a set of points called “**poles**” and NURBS order.

When creating a curve, custom poles can be specified. In order to create a surface, a set of poles should represent a grid built in the surface's parametric area (see Section 2.5.1.3), i.e. the poles must be positioned in rows with equal number of poles in each of them. Isoparametric curves of the future surface will run along these rows.

Evidently, the form of a spline curve or surface is defined by poles' position in space. Surfaces built by poles offer **local deformation** features that are very useful for modeling: changing position of one pole results in change of shape of only one surface part next to this point rather than the whole surface.

Spline's order in case of a curve is equal to the maximum degree of polynoms, describing sections of the curve, plus one.

The number of poles can be equal or exceed the order, but not less than the order. The order can not be less than 2. Particular cases of spline curves can be found in Fig. 2.5.3.

Fig. 2.5.3. Particular cases of spline curves:
 a) linear curve (number of poles – 2, order – 2, polynomial degree – 1),
 b) conic curve (number of poles – 3, order – 3, polynomial degree – 2),
 c) cubic curve (number of poles – 4, order – 4, polynomial degree – 3),

While creating a spline surface, two values defining the order by each direction should to be set: U and V. The order value set will be reflected in the isoparametric curves of the corresponding directions.

In practice, the spline order is rarely increased to anywhere larger than 6 due to significant complication (and the resulting slowing down) of calculations involved in operations with curves and surfaces.

The additional parameter which impacts on the spline curve shape is the **weight** of each pole. The geometrical meaning of this parameter is as follows: the greater is the pole's weight, the closer the curve is passing to the poles (i.e. points with a large weight “attract” the spline stronger than points with a small weight).

For example, Fig. 2.5.4 contains an example of curve shape change on increasing the weight of one of the poles. Position I of the curve corresponds to the case where all the poles have a unit weight, position II corresponds to the case where pole 4 has weight 2 whereas position III corresponds to the case when its weight equals 6.

Fig. 2.5.4. Influence of pole weight on curve shape

The curve shape is defined by the difference in the absolute weight of poles and not the weights proper - i.e. the curve shape will remain unchanged on multiplying the weights of all poles by the same value.

2.5.1.5. Basis vectors at a point of the curve

Each point of the curve is associated with three mutually perpendicular planes: a normal, osculating and aligning, as well as three mutually perpendicular basis vectors: tangent vector t , vector of the principal normal n , and binormal vector b (see Fig. 2.5.5).

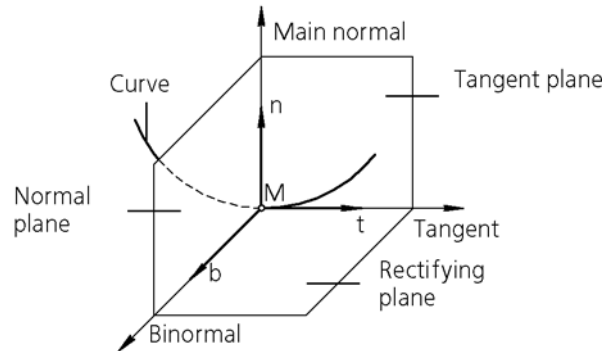

Fig. 2.5.5. Basis vectors at a point of the curve

The **tangent** and the **main normal** vectors lie in the osculating plane, and the **binormal vector is perpendicular** to this plane.

The osculating plane is the plane tending to take position of the plane passing through three curve points M , M_1 , M_2 , provided that points M_1 and M_2 tend towards M (see Fig.2.5.6).

Fig. 2.5.6. Osculating plane

The plane where tangent vector and binormal vector are located is an **aligning** plane, while the plane where vector of the principal normal and binormal vector are located is a **normal** plane.

2.5.1.6. Curvature of curve Osculating circle

Curvature of the curve in point M is the value that characterizes the curve's deviation off the osculating straight line near the point in that point.

Curvature of the curve in point M can be defined using the circle tangent to it in this point.

A tangent circle is an extreme position of the circle when it goes through point M and two other points M_1 and M_2 infinitely near to it (see Fig. 2.5.7). Tangent curve lies in the **tangent** plane of the curve in point M (see Section 2.5.1.5 on p. 331 for more information about tangent plane).

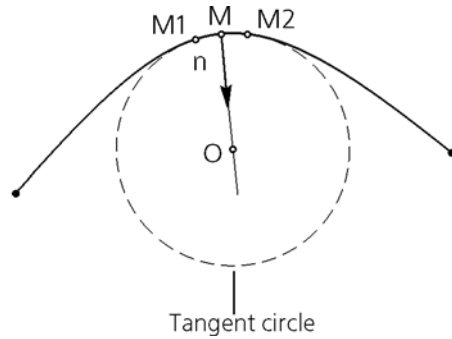

Fig. 2.5.7. Tangent circle in point M of the curve

Center of the circle tangent to the curve in point M is the **center of curvature** (O) of the curve in a given point while the radius of this circle is the **curvature R** of the curve in the point.

Radius of curvature (R) is a reciprocal of the curvature (K): $R=1/K$.

Center of the curve curvature is always located on the main normal.

2.5.1.7. Mating Condition for Curves and Surfaces

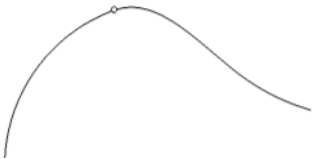

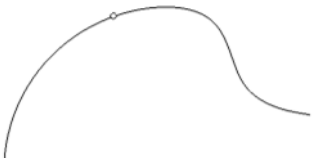

Mating condition determines the shape of curve or surface created near connection of such curve or surface to the existing curve or surface. Such existing curve or surface is a **mating object** to the created one. Curves are mated to one another and to surfaces in the **mating point** whereas surfaces are mated along a curve — the **mating border**.

Curves and surfaces mating results under various mating conditions are presented in Table 2.5.1. The Table also contains examples of curves joints under various mating conditions. The curve being the mating subject is shown on the left while the curve being mated is shown on the right. The mating point is marked with a circle.

Tab. 2.5.1. Mating condition for curves and surfaces

	Mating condition	Result of mating
	<p>Not specified The curve end point or surface boarder belong to the mating object.</p>	

Tab. 2.5.1. Mating condition for curves and surfaces

	Mating condition	Result of mating
	<p>By Tangent The Not specified condition is observed. The following additional condition is met:</p> <ul style="list-style-type: none"> ▼ for a curve: the curve and the mating subject have a common tangent at the mating point[*], ▼ for a surface: in the mating boundary points, isoparametric curves of the mated surface and of the mating surface have a common tangent. 	
	<p>Perpendicular The Not specified condition is observed. The following additional condition is met:</p> <ul style="list-style-type: none"> ▼ for a curve: the tangents of the curve and the mating subject are perpendicular at the mating point. ▼ for a surface: in the mating boundary points, tangents to isoparametric curves of the mated surface and of the mating surface are perpendicular. 	
	<p>Smooth The By Tangent condition is observed. The following additional condition is met:</p> <ul style="list-style-type: none"> ▼ for a curve: the curvature of the curve at the mating point is equal to that of the mating subject[*], ▼ for a surface: in the mating boundary points, isoparametric curves of the mated surface and of the mating surface have the same curvature. 	

* If the mating subject is represented by a surface, mating will require specification of the curve on the surface and passing through the mating point.

In some 3D modeling systems the process of mating curves or surfaces using **Not Specified** condition is referred to as “Mating with G0 Continuity”, using **By Tangent** condition - “Mating with G1 Continuity”, and using **Smooth** condition - “Mating with G2 Continuity”.

2.5.2. Points

Commands for creating 3D lines and points are located in **Operations** menu, and the buttons to call them are on the **3D Lines** panel (Fig. 2.5.8).

Fig. 2.5.8. 3D Curves bar

2.5.2.1. General procedure for point construction

Creating a dimensional point is possible using the following methods:

- ▼ **By coordinates (XYZ),**
- ▼ **By move relatively to the other point,**
- ▼ **At the intersection of two objects,**
- ▼ **On a line,**
- ▼ **On a surface,**
- ▼ **In the center of an object,**
- ▼ **By projection of a point on an object,**
- ▼ **By cylinder (RAZ),**
- ▼ **By sphere (RAB).**

The use of the specified object in each method provides an associative relation of the point to this object, for instance, pertaining of a point to a surface.

To create a dimensional point, apply the command **Point**.

Select a variant of point construction from the **Method** list or using commands of the context menu. The elements for managing construction will appear on the Properties Bar (Fig. 2.5.9).

Fig. 2.5.9. Property Bar for point construction by coordinates

Then specify parameters and objects used for construction.

Along with input of numerical values you can move the characteristic point by mouse to define the final position of the point, e.g. while creating on a curve. In such a case the relation with the object won't fail and the parameters shall be calculated and displayed in the fields of the Property Bar.

Parameter input for each method is detailed in Sections 2.5.2.2 — 2.5.2.9.

The ghost point appears in the model when all the required data has been specified. While construction is not yet finished, the location of the point can be changed by activation of the required control element on the Property Bar.

Before completion of the command the system "remembers" the objects specified in each construction method, therefore you can switch between the methods without loss of the objects. The exclusions are **By Coordinates (XYZ)**, **By Cylinder (RAZ)**, **By sphere (RAB)** methods: switching to any of them will result in automatic creation of the point that coincides with the point defined in the last of the selected methods. Due to it, at any moment of point construction

you can view its current coordinates in the Cartesian, cylindrical or spherical coordinate system.

To create a point without an associative link with the objects used during construction, switch, for example, to the **By Coordinates (XYZ)** method and complete the command.

To change the objects used for point construction by means of the selected method, click the **Select Other** button on Special Control Panel and repeat object selection.

Name, color and display style of a point can be customized on the **Properties** page of the Property bar.

To finalize the construction, click the **Create Object** button on the Special Control Panel.

In the **By Coordinates** and **In Center** methods, automatic creation of objects is available and enabled by default.

2.5.2.1.1. Objects Used for Construction

During construction, two types of objects are used: objects that include the point and auxiliary objects: base points and guide objects (in **Move** and **Projection** methods).

Points in the model can be located on spatial curves and surfaces and also can coincide with point objects.

Point Objects are:

- ▼ Coordinate system origins,
- ▼ sketch line vertices,
- ▼ Standalone points in sketches,
- ▼ standalone dimensional points,
- ▼ vertices of dimensional curves,
- ▼ edge vertices.

Base Point is the reference point for offset in the **Move** method and the projected object in the **Projection** method. Any point object can be a base point.

Guide Objects designated to set the offset direction or the point projection can be the following objects of a model.

- ▼ Point objects (listed above).

The direction defined by a point object is a line passing through this point object and the specified base point.

- ▼ Straight objects:
 - ▼ sketch line segments,
 - ▼ polyline segments,
 - ▼ coordinate and auxiliary axes,
 - ▼ straight edges.

Direction, defined by a straight object — a line parallel to the object.

- ▼ Flat (planar) objects
 - ▼ coordinate and auxiliary planes,
 - ▼ flat faces.

Direction, defined by a plane object — a line perpendicular to the object.

Moreover, the guide object may be represented by a vector. This vector can be created by means of **Vector drawing** command (see Section 2.8.5 on p. 613).

2.5.2.2. Construction of point by coordinates XYZ

By Coordinates (XYZ) is a method of point construction allowing you to directly set its Cartesian coordinates in space or link it to an existing point object.

Point coordinates can be input from a keyboard or defined automatically by positioning the mouse in the model window. Associative linking of the point with the point object is enabled and disabled by the **Associate** option.

- ▼ If all the three point coordinates are known, enter them to the corresponding fields of the Property Bar and fix them by pressing the <Enter> key.
- ▼ When you move the mouse in the model window, the point is defined as the cursor projection on the surface parallel to screen and running through the origin of coordinates. Current coordinates of the point are displayed in the **X**, **Y**, **Z** fields of the Property Bar. When you move the cursor to the point object (list of objects see in the Section 2.5.2.1.1), a cosmetic vertex or point appears next to it, and the coordinates are defined as those coinciding with the coordinates of this point object. To fix the point with the current coordinates, click the left button of the mouse.

Selecting of the point object when **Associate** option is on will enable the forming of associative relation between the point and this object.

The presence of relation is manifested by displaying a checkmark on the **Object** button and the name of the point object in the **Object** field on the Property Bar. Due to this relation, a newly created point will follow the object when the latter is repositioned.

To cancel the associative relation with the point object, click the **Object** button. The tick on the button will disappear.

To restore an associative relation of a point and a point object, enable the **Auto association** option and specify the required object anew.

- ▼ If two coordinates of the point are known, enter them into the corresponding fields of the Property Bar and fix them. While you move the mouse, the point will move along the straight line defined by the specified coordinates. To create a point as a projection of any point object on this line, disable the **Associate** option and select the required point object. To fix the point, click the left button of the mouse.
- ▼ If one coordinate of the point is known, enter it into the corresponding field of the Property Bar and fix it. While moving the mouse, the point will move along the plane defined by the specified coordinate. To create a point as a projection of any project object on this plane, disable the **As-**

sociate option and select the required point object. To fix the point, click the left button of the mouse.

Point coordinates are specified in that point's coordinate system (for object coordinate system refer to Section 2.8.3.4 on p. 597).

2.5.2.3. Moving a Point with respect to Object

Move is a method of point construction by defining the coordinates in relation to the base point or by offsetting from it for the predefined distance in the specified direction.

For base points, you can use the same point objects as those used for linking the points to the object in the **By Coordinates** method.

To create a point by the **Move** method, select a base point, i. e. the point specified as the coordinate origin or the reference point to count the offset distance.

To select the base point, specify the required object while clicking the **Base Point** button. After a cosmetic vertex or a point appears next to the cursor, click the left mouse button. Its name will appear in the **Base Point** field.

2.5.2.3.1. Move by coordinates

Fields for coordinates input become accessible after specifying the base point.

Enter the relative coordinates of the point being created in the **X,Y,Z** fields of the Property bar and fix by pressing the *<Enter>* key.

Relative coordinates are set in the Cartesian coordinate system, the origin of which is a base point and the axes run in the same directions as the axes of coordinate system of the point being created (for object coordinate system see Section 2.8.3.4 on p. 597).

2.5.2.3.2. Move Relatively to Guide Object

After specifying the base point, press the **Guide Object** button.

In the model, select the object to define the direction for the offset of the point to be created from the base point. The list of guide objects and directions they define are specified in Section 2.5.2.1.1 on p. 335.

Moreover, the guide object may be represented by a vector. Such vector can be created by means of **Vector drawing** command (see Section 2.8.5 on p. 613).

In the **Guide Object** field, the name of the selected object will appear. If the direction is set by means of a vector, the field will contain the word "Vector".

After the guide object is specified, the **Distance** field becomes accessible.

Specify the distance from the base point to the point to be created by entering it into this field or selecting the point's position by mouse in the model window.

Instead of the distance to be defined, you can specify a point object. In this case, a point will be created that is a projection of the specified object onto the offset direction.

2.5.2.4. Point construction on Intersection of Objects

Intersection is a method to construct a point on the intersection of two objects. Objects are axes, dimensional curves and their segments, edges, sketch lines, faces of surfaces and solids. The point is automatically created subject to the required condition: availability of a finite number of object intersection points.

To create a point, complete the following steps.

1. While the **Object 1** button is pressed, select by cursor an object in the model: a curve or a surface. The name of the object selected shall be displayed in the field **Object 1**.

2. While the **Object 2** button is pressed, select by cursor the second object in the model that intersects the first object. The name of the object selected shall be displayed in the field **Object 2**. If the object does not have any common points with the first one or the number of common points is infinite, then the definition in the **Object 2** field will be unavailable. In this case, you should specify the second object again or select another pair of objects.

You can select objects in any sequence.

After both objects are defined, a ghost of the point will appear on the screen.

To use another object for performing the command, click the **Object 1** or the **Object 2** button. Selection of an object will be cancelled and you will be able to select a new object.

If there are several points of intersection, then they will be displayed one-by-one when you click the **Next Object** buttons and **Previous Object** on the Special Control Panel. After the required point appears on the screen, finish the construction of the object.

2.5.2.5. Point Construction on Curve

On Curve is a method to create a point offset along the curve for some distance from its vertex. The distance can be specified in relative or absolute values.

You can select a 3D curve or its segment, a sketch line or an edge as a curve.

To create a point on a curve, perform the following steps.

1. Select a curve in the model by cursor. The selected curve will be highlighted in the model. Two ghosts will be created on the curve: a point in the specified place and a start vertex with a directing arrow to count the distance. At the same time, in the **Curve** field on the Property Bar, the name of the selected object will be displayed.
2. Move the characteristic point by mouse along the curve to the required position.

Also, you can specify the offset numerical value on the Property Bar. To do this select a specification option from the **Offset** drop-down list containing the available method options.

- ▼ **At % of curve length** by relative value of the offset from the initial point to the characteristic point. The percentage value for entering into the **% of curve length** input field should be from 0 to 100 of the curve length.

- ▼ **By Segment Length**— by the length of the curve from the initial point to the characteristic one. The **Segment Length** field is used to specify the absolute offset in the length measurement units.

- ▼ **By Arc Central Angle** — by the central angle between a initial point to the characteristic one. The variant is available when an arc of circle or ellipse is selected as a curve. The **Angle** field is used to set the central angle of the arc in angle measurement units.

After the curve is selected, the field for the current parameter will display its value in the point on the curve. When moving the point by mouse, the parameters are calculated and put to these fields.

Enter or specify by counter the value of the offset parameter.

During construction, you can switch between the options. In this case the offset value will be calculated and displayed in units of the selected option.

You can construct a point on a curve by linking it with an existing point object. For that, select a point object (for list of objects — see Section 2.5.2.1.1 on p. 335).

The position of the point is determined by the shortest distance from point object to the curve.

Owing to associative link, the newly created point will follow the object whenever its position is changed. The presence of relation is manifested by displaying a checkmark on the **Object** button and the name of the point object in the **Object** field on the Properties Bar. In this case the field for inputting point offset along the curve is not available for editing.

To cancel the associative relation with the point object, click the **Object** button. The tick on the button will disappear. After that, the point offset field is editable again.

To restore the associative relation of the point with the point object, specify the required object again.

While the **From Start Vertex** button is pressed of the **Direction** switch group, the offset is measured from the start vertex of the curve in the direction of the offset vector. To change direction, click the **From End Vertex** button.

Unless the offset is not specified by the user, the change of direction will not change the point position on the curve.

2.5.2.6. Construction on Surface

On surface is a method to construct a point lying on a surface. The following can be used as surfaces:

- ▼ faces of surfaces and bodies,
- ▼ coordinate planes.

The point's position can be set:

- ▼ by moving theoretical surface of the selected face along isoparametric curves U and V,
- ▼ by moving (linear or angular) the point from two specified reference objects;
- ▼ coordinates on the surfaces:
 - ▼ flat (two types of coordinates—orthogonal and polar—are available),
 - ▼ cylindrical (in cylindrical coordinate system),
 - ▼ spherical (in spherical coordinate system).

For more information on theoretical face's surface and isoparametric curves, see Section 2.5.1.3 on p. 328.

In order to create a point on a surface, it is necessary to specify the surface, choose the variant of point position specification, and specify parameters that define the position.

In order to specify the surface, use the cursor to select a face or plane in the model while the **Surface** button is enabled. The selected object will be highlighted and its name will appear in the **Surface** field.

In order to choose the variant of specifying the point's position, choose the respective line in the **Offset** list. Variants are described in detail in Sections 2.5.2.6.1-2.5.2.6.4.

The **Allow for borders** option makes it possible to limit the point's position by the face's contour: if the option is enabled, the point may be positioned inside the contour; if the option is disabled, it can be positioned both inside and outside (if necessary, the face's theoretic surface will be extended). If you build the point on an auxiliary or coordinate plane, the **Allow for Borders** option will not be available.

2.5.2.6.1. By parameters U and V

This variant of specifying the point's position is used when the relative values are known or if you need to create a point lying on a theoretical surface.

If this variant is chosen, the ghost of the face's theoretical surface appears on it as a grid of intersected isoparametric curves. The ghost contains the following indications:

- ▼ arrows to show the directions of U and V parameters effect in the start point $U=0, V=0$;
- ▼ dashed lines to indicate ghosts of U and V parameters in the specified point.

In the Property bar, the following fields are present: **Parameter U, %** and **Parameter V, %**. In these fields, the current parameters U and V in the point of face specification will be displayed.

Methods of specifying the position of a point on a surface

▼ Moving the handle in the model window

When moving a handle (about handles, see Section 2.1.4.2.2) current parameters setting the position of the point are displayed in respective fields.

▼ Inputting parameters setting the position of a point in respective fields on the Properties bar

Input U and V parameters or set them using counter and fix by pressing *<Enter>*.

▼ Linking with point object

Move the pointer to the point object (list of objects — see Section 2.5.2.1.1 on p. 335) — a symbol of vertex or point will appear next to the object. The point's position is defined as a projection of the specified point object on the construction surface. Owing to associative link, the newly created point will follow the object whenever its position is changed.

The presence of relation is manifested by displaying a checkmark on the **Object** button and the name of the point object in the **Object** field on the Properties bar. U and V parameters are displayed in respective fields on the Properties bar, and they are not editable.

To cancel the associative relation with the point object, click the **Object** button. The tick on the button will disappear.

To restore the associative relation of the point with the point object, specify the required object again.

2.5.2.6.2. By offsets from two objects

The **By offsets from two objects** variant is applied if offset (linear or angular) of the point from two reference objects is known.

In the **general case**, the point is located on an arbitrary surface, while offset is set by distances between it and two flat objects. The following objects may be used as flat objects:

- ▼ flat faces,
- ▼ auxiliary and coordinate surfaces,
- ▼ edges in the form of flat curves,
- ▼ sketches (in the Design Tree).

Flat objects must meet the following requirements:

- ▼ they must be non-parallel to each other,
- ▼ the line of intersection of their planes should not be parallel to the surface (or forming surface) on which the point is located.

Besides that, the following **special cases** are possible:

- ▼ if the point is positioned on a *flat face*, you can use a straight-line edge as a reference object for it; in this case, offset will be counted from the plane going through the edge perpendicular to the flat face;
- ▼ if the point is positioned on a *rotation surface (except for spherical surface)*, you can specify an angular offset from the plane going through the surface's axis (offset from the second object will be linear in this case); in order to specify such plane, you can specify a coincident flat object and a straight-line edge within it.

If the **By offsets from two objects** variant is selected, the **Object 1** and **Object 2** fields will appear in the Property bar. These fields will display names of objects from which the point's offset is calculated. The objects are automatically identified by the system.

Groups of switches **Type of Parameter 1** and **Type of Parameter 2** can be used for specifying the offset type (linear or angular).

You can switch between parameter types, if the point is built on the rotation surface, and a plane going through the rotation axis is selected as a reference object. In other cases, the parameter type is defined by the system automatically and it is impossible to change it.

The **Distance 1/Angle 1** and **Distance 2/Angle 2** fields display calculated offsets of the point at its current position with respect to specified objects.

The model window displays arrows denoting positive direction of offset counting.

Edit offset values; if necessary, change reference objects and/or offset type. Note that entry of offsets is possible only if both reference objects are defined.

As the second reference object, you can specify only such an object which results in finite number of points when surface and the first reference objects are selected.

Methods of setting the position of a point are similar to those used in the **By U and V parameters** (see Section 2.5.2.6.1 on p. 340).

If several points on the surface meet the defined conditions, the following buttons will become available on the Special Control panel: **Next object** and **Previous object**. Using these buttons, choose a point for construction and finish creating the object.

2.5.2.6.3. By coordinates on plane

The **By coordinates on plane** variant is applied if you need to create a point on plane by specifying its rectangular or polar coordinates.

If you use this variant, the Property bar will display the **Type of coordinates** group of switches for selecting the type of coordinates when constructing the point:

▼ **Rectangular coordinates,**

▼ **Polar coordinates.**

If **rectangular coordinates** are chosen for creation of the point, **X** and **Y** fields will appear in the Property bar; if **polar coordinates** are chosen, **R** and **A** fields will appear in the Property bar. By default, the point is located in the point of plane specification. Current coordinates of the point are displayed in the respective fields of the Property Bar.

Methods of setting the position of a point are similar to those used in the **By U and V parameters** (see Section 2.5.2.6.1 on p. 340).

2.5.2.6.4. By coordinates on cylinder and sphere

The **By coordinates on cylinder** variant is used if you need to construct a point on a cylindrical surface using **cylindrical coordinates**. When you choose the method, the **A** and **Z** fields appear on the Properties bar.

The **By coordinates on sphere** variant is used if you need to construct a point on a spherical surface using **spherical coordinates**. When you choose the method, the **A** and **B** fields appear on the Properties bar.

For more details on cylindrical and spherical coordinates, see Section 2.5.3.4.1 on p. 358.

To construct a point in cylindrical coordinates it is required that the origin of the current coordinate system is on the axis of a cylindrical surface that coincides with the Z axis of the coordinate system, while to construct a point in spherical coordinates it is required that the origin of the current coordinate system is the center of a sphere.

Choosing the **By coordinates on cylinder (sphere)** variant is available, if there is a cylindrical (spherical) surface meeting the above requirements on which the point is to be placed. An vice versa, if the variant is selected, you can select only such cylindrical (spherical) surfaces that meet the requirements.

By default, the point is placed in the point specified on the surface. Current coordinates of the point are displayed in the respective fields of the Property Bar.

Methods of setting the position of a point are similar to those used in the **By U and V parameters** variant (see Section 2.5.2.6.1 on p. 340).

2.5.2.7. Construction of point in the Center of Object

In Center is a method to create a point in the center of an object (for bodies and faces — in the center of gravity).

The objects are:

- ▼ sketch contours being circles, ellipses or their arcs,
- ▼ sketch lines being circles, ellipses or their arcs,
- ▼ spherical surfaces,
- ▼ bodies,
- ▼ faces.

To create a point, select an object. The object's name will be displayed in the **Object** field. In the model, the point will be created automatically.

Bodies are selected in the Design Tree of the model. The body icons and names are shown on the Tree if the model structure is enabled (see Section 2.1.2.2 on p. 106).

When calculating the face's mass center, only its external contour is taken into account.

2.5.2.8. Construction of Projection of Point on Object

Projection is a method to create a point as a projection of a base point on an object.

Any point object can be a base point.

Objects on which a base point is projected are:

- ▼ faces, auxiliary and coordinate surfaces;
- ▼ edges, dimensional curves, sketch lines, auxiliary straights, coordinate axes.

Projection can be orthogonal or constructed in the direction specified by an object. The list of objects and directions they determine are indicated in Section 2.5.2.1.1 on p. 335.

Moreover, the guide object may be represented by a vector. Such vector can be created by means of **Vector drawing** command (see Section 2.8.5 on p. 613).

To create a projection, complete the following steps.

1. Select a base point. The name of the point will be displayed in **Base Point** field.

2. With the **Object** button pressed, select the object, which the base point is projected on. The name of the object will be displayed in the **Object** field, and in the model, a ghost of an orthogonal projection of the point will appear.

3. Finish creation of the point, if construction of orthogonal projection is required.

Select the guide object or create a vector in order to construct a projection in a pre-determined direction. Click button **Guide Object** and then select the direction reference object or create a vector.

The ghost will change its location. Complete the point creation.

The point is built only if the projection falls into the object and not into its continuation. Exceptions are the flat surface and revolution surface— projection may be created on their extensions.

Auxiliary and coordinate planes and axes are infinite, therefore, a projection is created regardless of its position respect to the rectangle or the line segment, representing a flat or an axis.

2.5.2.9. Construction by Cylindrical (RAZ) and Spherical (RAB) Coordinates

By Cylinder (RAZ) is a method of point construction that allows you to set the point's cylindrical coordinates (R, A, Z) in space or link it to an existing point object.

By Sphere (RAB) is a point construction method allowing you to set the point's spherical coordinates (R, A, B) in space or link it to an existing point object.

For more information about the cylindrical and spherical coordinate systems location relatively to the coordinate system see Section 2.5.3.4.1 on p. 358.

You can set sphere or cylinder radius by entering its value in the R coordinate field or by selecting an object defining a radius value.

To select the object defining radius, enable the **Radius Object** and select the required object:

- ▼ an edge or a line in a sketch having the form of a circle or a circle arc,
- ▼ a curve — a circle or an arc,
- ▼ a cylindrical or spherical edge.

The value of the specified object's radius is specified in the **R** field. An associative relation is formed between the point and the object. Therefore, the **R** field becomes unavailable. To cancel the link, enable the **Radius Object** switch and reselect the object.

Other methods used for point creation **By Cylinder (RAZ)** and **By Sphere (RAB)** i.e. input and locking of point coordinates, linking a point to the already existing point object, are the same as those used for point creation **By Coordinates (XYZ)** (see Section 2.5.2.2 on p. 336).

If two objects are selected for point creation: point radius and defining radius, then a point is created as a projection of a point object on a cylinder or a sphere of respective radius.

2.5.2.10. Point Variables

After a point is created in a model, the variables of this point are automatically created.

The point variables include three informational ones. They correspond to the Cartesian coordinates of a point. These variables are always created.

Availability and contents of other variables are preconditioned by the point creation method (Table 2.5.2).

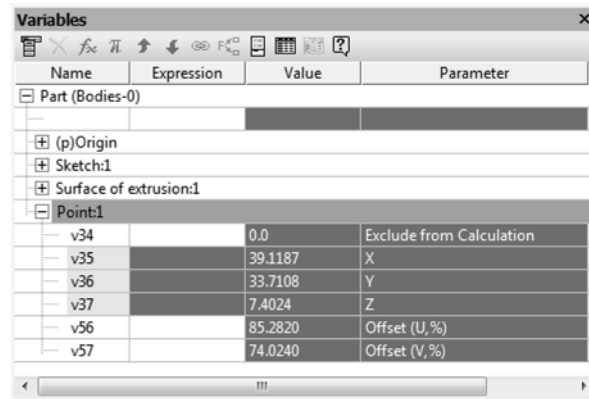

Tab. 2.5.2. Point Variables

Point construction method	Variables
By Coordinates	<ul style="list-style-type: none"> ▼ X coordinate ▼ Y coordinate ▼ Z coordinate
Move	<ul style="list-style-type: none"> ▼ relative coordinate X ▼ relative coordinate Y ▼ relative coordinate Z or ▼ offset distance
On curve	<ul style="list-style-type: none"> ▼ offset value (offset amount in %, the arc length, or central angle) ▼ offset direction
On surface	<ul style="list-style-type: none"> ▼ U parameter value in % ▼ V parameter value in % or ▼ offset from the first flat object ▼ offset from the second flat object or ▼ X (or R) coordinate ▼ Y (or A) coordinate

If the point is created in local system of coordinates (rather than in absolute system), most construction methods will result in such point having only informational variables.

Figure 2.5.10 illustrates the variables of the point created by the **On Surface** method.

Name	Expression	Value	Parameter
Part (Bodies-0)			
(p)Origin			
Sketch:1			
Surface of extrusion:1			
Point:1			
v34		0.0	Exclude from Calculation
v35		39.1187	X
v36		33.7108	Y
v37		7.4024	Z
v56		85.2820	Offset (U,%)
v57		74.0240	Offset (V,%)

Fig. 2.5.10. Point variables

Work with variables and expressions is described in detail in Section 7.1 on p. 1569.

2.5.2.11. Using point command functionality while creating other objects

To construct a point using options available in the **Point** command is possible by the following commands:

- ▼ Spline,
- ▼ Polyline,
- ▼ Line segment,
- ▼ Graphic Circle Arc,
- ▼ Surface created by the point grid,
- ▼ Surface on grid,
- ▼ Control point,
- ▼ Attachment Point,
- ▼ Axis through the Vertex,
- ▼ Scaling;
- ▼ Plane Tangential to Face at Point;
- ▼ Plane through Vertex Perpendicular to Edge,
- ▼ Create zone,
- ▼ Create/edit section,
- ▼ Add from file,
- ▼ Add local part from file,
- ▼ Base part,
- ▼ Place component.

The steps for forming a contour through tracing by arrow are described in Section 2.5.2.11.1.

It should be noted that execution of the **Axis Through Vertex Along Object** and **Scaling** commands as well as those enabling construction of auxiliary planes results in visualization of constructed points as individual objects in the Design Tree. Editing these points result in changing their parameters.

The points constructed using other commands are stored inside the objects created by such commands and are not displayed in the Design Tree. You can change their parameters directly rather than through editing the objects such points were created for. For information about the procedure and options of editing such points, see Section 2.5.2.11.2.

When adding a component to a model or editing its position parameters, and when creating/editing model sections new points are not created at all. The point construction process is used only for determining the position of the point of inserting a component or the points that determine the position of a section (flat or block-like).

2.5.2.11.1. Constructing a point during object creation

To finalize the construction, click the **Create Point** button on the Special Control Panel.

System starts a point creation process fully corresponding to the process enabled by the command **Point** (see Section 2.5.2.1 on p. 334). Select a point creation type, then subsequently specify the required parameters (enter the values or specify the objects). The created point is displayed as a ghost.

Upon completion of the point parameterization click the **Create Object** button on Special Control Panel.

The systems gets back to the command for which the point was constructed.

Name of the point construction type is highlighted in the special field on the Property Bar. If the point is constructed **By coordinates (XYZ)**, the point coordinates will be highlighted.

Fig. 2.5.11. Parameters of the point built while constructing an arc displayed in the Properties bar

Please note the following peculiarities of constructing points when creating a polyline or spline.

- ▼ When constructing a point while button **Create Object** is pressed, the point becomes fixed with no return to polyline or spline construction process. This allows to create several curve vertices in sequence. To finish the point creation process, click the **Create Object** button.
- ▼ The spline or polyline parameters table will highlight the point coordinates without their construction types.

2.5.2.11.2. Edit a point constructed during object creation

1. Enter the mode to edit the inscription.
 2. Select (in the model window or with the aid of the Property Bar control elements) an object point to be edited. No selection is necessary while editing a control or attachment point.
- Note: When you move cursor to the point, its construction method and coordinates will be dis-

played next to the cursor. For control or attachment point, the method of point construction is displayed in the **Point** information field on the Property bar.

3. Set the new position of the point by doing one of the following:

- ▼ In the model window select the point object. Information about the constructed point is erased, and the edited point coincides with the specified object. If option **Associate** is enabled on the Property bar, the point will be associated with the object.

- ▼ Click the **Create Object** button on the Special Control Panel. The object editing process starts, which is similar to the initial construction process. Change parameters of the active point creation type or select another type and create a new point. After finishing editing, click the **Create Object** button to exit point edition process.

- ▼ When editing an arc, surface, spline or polylines a point can be moved with a mouse in accordance with the point construction method. For example, the point on curve can be moved along this curve. Some construction methods, e.g., **At Intersection**, do not allow for the point free movements.

- ▼ A point associated with a point object can not be moved in arbitrary manner — it follows the point object. You can delete relation. To do this, complete the following steps:

- ▼ in the arc edit mode: click the **Object** button on the Property bar,

- ▼ in the spline or polyline edit mode: disable option in the **Relation with Point Object** column in the Table of vertices,

- ▼ in the surface edit mode: enable the point edit mode by clicking **Create Point** on the Special Control panel, click **Object** on the Property bar, and then — **Create Object**.

Upon deletion of the associative relation, the point remains coincided with the point, however, it can be freely moved with a mouse.

Control or attachment point is always object-associated.

4. After finishing editing, click the **Create Object** button. The sketch will be highlighted in the model window.

2.5.3. Point Groups

Spatial points can be created in groups on an existing object — i.e. a curve or a surface. Such groups can be created using the points coordinates saved in a file.

Commands to create point groups are located in the **Operations** menu.

Their shortcuts are grouped on the **3D Curves** panel (Fig. 2.5.12).

Fig. 2.5.12. Commands to Create Point Groups

2.5.3.1. General Techniques for Creating Point Groups

After calling the group creation command select the object whose surface would contain the group elements. Its name will appear in the field on the Properties bar.

If the point group is created using the data from a file, select the file name and path. The file name will appear on the Properties bar.

Set the parameters of the group and the point properties using the fields and switches on the Properties Bar.

The ghost of the point group is displayed on the screen. This allows you to evaluate correctness of parameterization and selection of initial features.

If necessary, change the group's name, color, and point display style. For that, use control elements on the **Properties** tab of the Property bar.

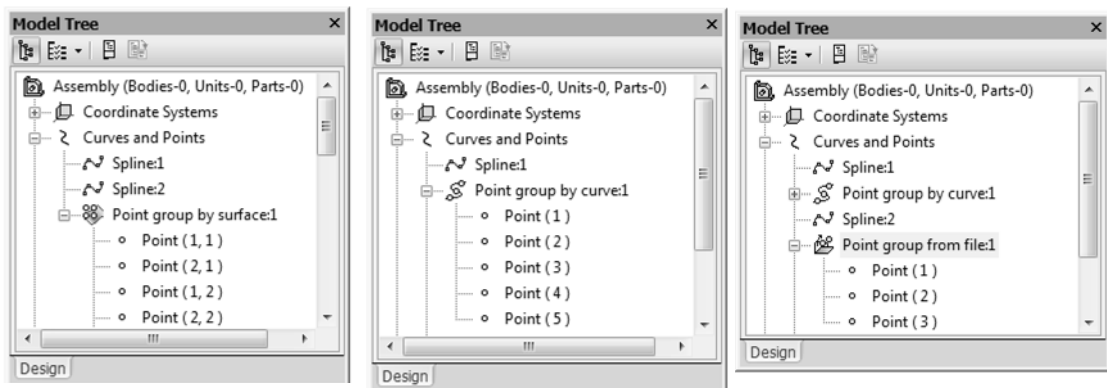

Confirm group creation.

The created group of points will appear in the model window, and the icon corresponding to its type — in the Design Tree (Fig. 2.5.13 on p. 349).

A point group consists of **elements**.

The point group elements are displayed in the Design Tree as separate objects subordinated to the group.

To expand the list of elements, click the mouse on the “plus” sign located at the left of the group icon in the Design Tree.

a) Along surface;

b) Along curve;

c) From file.

Fig. 2.5.13. Point group in the Design Tree

The group element ID number is displayed in parentheses to the right of the group element icon.

If the group is built along a surface, the group element number will contain two numbers. The first value is the element number by V parameter whereas the second one is the element number by U parameter. Instance numbering begins with one.

A point group can be broken up into separate elements (see Section 2.5.3.1.1 on p. 350).

If the **Scatter** option was selected while creating the group, the position of points in completing the command will correspond to the settings. However, they will not be the group elements. The status of the resulting points will be identical to the result of the **Explode** command.

2.5.3.1.1. Exploding a group of points

A point group can be broken up into separate elements.

You can do this by selecting a group of points to be exploded in the Design Tree and using the **Explode** command from the **Editor** menu.

In order to explode a single group of points, the **Explode** command may be called from the point group's context menu in the Design Tree.

Upon calling the command, an explode dialog will appear. To confirm explosion, click **OK** in this dialog.

The rules of exploding groups are as follows:

- ▼ icon of the group and of its objects will be deleted from the Design Tree;
- ▼ objects that used to constitute the group retain their positions in the group.

The types of objects generated by array explosion depend on the types of the group's source objects (Table 2.5.3).

Tab. 2.5.3. Results of Exploding a Group of Objects

Source Object Type	Types of Objects Resulting from Group Explosion
Group of Points Along a Curve	Point created by the On Curve method
Point groups along a surface	Point created by the On Surface method
Group of points from a file	A point created using By coordinates (XYZ) , By cylinder (RAZ) or By sphere (RAB) methods depending on the interpretation method with respect to data obtained from the file.
group of isoparametric curves on the surface,	Isoparametric curve.

2.5.3.2. Point Group Along a Curve

To create a point group along a curve run the **Point Group Along Curve** command.

Select the curve to contain the points. You can select a 3D curve or its segment, a sketch line or an edge as a curve.

The object name will appear in the **Curve** field.

The group ghost will appear in the model. The end points of the ghost are its handles. The handles can be used for setting the **working segment of the curve** — i.e. the part of the curve within which the point group is to be constructed.

The number of points in the group and their relative position can be managed by means of the controls which become accessible on selection of one of the options from the **Method** drop-down list (see Section 2.5.3.2.1).

The position of the working section of the curve can be controlled the following ways:

- ▼ By moving the handles with the mouse;
- ▼ By using the controls located in the Properties bar (see Section 2.5.3.2.2).

2.5.3.2.1. Setting the position of points along the working segment

The methods of positioning the group points along the working segment of the curve can be set selected from the **Method** drop-down list on the **Parameters** tab of the Properties bar.

Method Uniformly Along Length

Group of points creation with the use of this method is processed as follows.

1. The start and end points of the group coincided with the respective boundaries of the working segment of the curve.
2. The remaining points are positioned between them at an equal step along the curve.

Input or select in the counter desired number of group points into the **Number of Points** field.

Method Step Along the Curve

Group of points creation with the use of this method is processed as follows.

1. The start point of the group coincided with the start boundary of the working segment of the curve.
2. The remaining points are positioned after it with preset step along the curve.

Input or select in the counter required distance between points in the group into the **Pitch** field.

The **Along Entire Curve** option is available for this method. If it is enabled, within the whole working section of the curve there will be created the group with the number of points equal to the result of integer division of the curve length by the indicated step plus one point. This result will appear in the **Number of Points** read-only field.

If the option is disabled, the **Number of Points** field becomes editable. From the starting point of the working section there will be created as many points with the selected step as has been set in this field.

The product of the step by the number of points less one must not exceed the curve length.

Method

Uniform Step by Curve Parameter

Group of points creation with the use of this method is processed as follows.

1. The start and end points of the group coincided with the respective boundaries of the working segment of the curve.
2. There are points in the parametric field of the curve (see Section 2.5.1.2 on p. 327) related to the boundaries of the working segment of the curve. A part of the parametric field limited by these points is split into equal parts. Number of parts is equal to $n-1$, where n is the assigned number of points.
3. Splitting points are reflected to the curve from the parametric field. The remaining points of the group will be aligned with the points found.

Use the counter to select or type the number of points to be created in the **Number of Points** field.

If the curve on which the points must be situated is **Multi-Segment**, group of points creation is processed as follows.

1. Every curve segment has its parametric area. Parametric areas of the curve segments are equal to each other and contain the **total area** within which a group of points is created.
2. The start and end points of the group are mated with the respective boundaries of the total area.
3. Total area is split into equal sectors (see Fig. 2.5.14, a). Number of parts is equal to $n-1$, where n is the assigned number of points.
4. Splitting points are reflected from the total area to the curve's segments (see Fig. 2.5.14, b). The remaining points of the group will be aligned with the points found.

Fig. 2.5.14. Polyline as an example of creating a group of 7 points:
 a) splitting of the total parametric field of the polyline into 6 equal segments,
 b) reflection of the splitting points on the polyline's segments

2.5.3.2.2. Setting the position of working segment on the curve

The controls enabling setting of parameters which determine the position of working segment on the curve are available for all the construction methods.

The **Change Direction** switch enables selection of the curve vertex to serve as the starting point of the working segment.

By default groups are constructed from the end points of a curve. The **Offsets** option enables setting the working segment offset from the curve vertices. If this option is activated, the user may access the controls for the offsets. The option is enabled automatically if you reposition the working section by moving handles.

Group of switches **Working Segment Border** enables setting the extreme point of the working segment for which the offsets are being determined. You can set offsets for the starting and end points by using these switches one after another.

Also the user may specify the numerical values for each offset on the Properties bar. To do this, you must select a specification option from the **Offset** drop-down list containing the parameter types.

- ▼ **In % of curve length.** The percentage value for entering into the **% of curve length** input field should be from 0 to 100 of the curve length.

- ▼ **By segment length.** The **Segment Length** field is used to specify the absolute offset in the length measurement units.

- ▼ **By Central Angle of Arc.** The **Angle** field is used to set the central angle of the arc in angle measurement units. The method is available when an arc of a circle or an ellipse is selected as a curve.

The parameters are calculated and put into these fields while the handle is being dragged with the mouse.

Set the offset parameter value by using the counter or the keyboard.

During construction, you can switch between the options. In this case the offset value will be calculated and displayed in the units of the selected option.

With the **From Start Vertex** button of the **Direction** switch group pressed, the offset is measured from the start vertex of the curve in the direction of the offset vector. To change direction, click the **From End Vertex** button.

2.5.3.3. Point Group Along Curve

You can create a group of points on a surface. The surfaces may be faces of surfaces and solids.

The command execution results in a pattern of the grid of points. The points of the grid can be represented by the vertices of a polyhedron approximating the initial surface based on the specified parameters.

In order to create a group of points on a surface, do the following.

1. Call the **Point Group on Surface** command.
2. After calling the command, the **Surface** switch is enabled on the Property bar automatically. Specify the face to which the points should belong.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

The name of the object will be displayed in the **Surface** field of the Properties bar upon selection of the object.

The selected face will be highlighted in the model. The following objects will appear on the face:

- ▼ ghost of its theoretical surface; arrows to show the directions of U and V parameters effect in the start point $U=0, V=0$;
- ▼ ghost of a point group; dashed lines to indicate ghosts of U and V parameters in the specified point.

For more information on theoretical face surface, see Section 2.5.1.3 on p. 328.

3. Choose the method of points' location within the group from the **Method** drop-down list in the Property Bar. Then, set parameters required for this method. The methods for creating groups are given in Table 2.5.4.

Tab. 2.5.4. Methods of constructing point groups along a surface

Method	Construction procedure
 By the Number of Points along U and V Axes	<p>The number of points in U and V directions is user-defined. Use the counter to select or type the number of points in this direction in the Number of points, U and Number of points, V fields.</p>
 By Linear Deviation*	<p>The points are constructed in such a way that the deflection of edges of the approximating polyhedron connecting the adjacent points in U and V directions from the surface does not exceed the value set by the user. Use the counter to select or type the value of the maximum deviation in the Linear deviation field.</p>
 By linear deviation*	<p>The points are constructed in such a way that the angle between the tangent to the surface at the point and the edge of the approximating polyhedron connecting the point with the adjacent ones in U and V directions does not exceed the value set by the user. Use the counter to select or type the value of the maximum angular deviation in the Angular deviation field.</p>
 By grid around the defined point	<p>The points are positioned on the specified face's theoretical surface so that they form a grid around the defined point on the same theoretic surface. The defined point is the grid's center. The grid may be rectangular, concentric, or hexagonal. Examples of point groups built using this method, are shown in Fig. 2.5.15; the grid's center is marked by a circle. The grid's center position setting is described in Section 2.5.3.3.1 on p. 355, grid parameter setup is described in Section 2.5.3.3.2 on p. 357.</p>

* While choosing the methods by linear and angular deflection the density of points on the surface will depend on its curvature. The point density will be larger and smaller at segments with larger and smaller curvature, respectively.

Fig. 2.5.15. Group of points constructed using the **By grid around the defined point**:
a) rectangular grid; b) concentric grid; c) hexagonal grid

4. Choose a point group construction variant using the **Allow for borders** option.
 - ▼ If the option is enabled, the point group will be constructed within the specified face's contour.
 - ▼ If the option is disabled, the group is constructed on the face's theoretical surface.
- Variants of point group construction on a face with a hole are shown in the figure.

Fig. 2.5.16. An example of constructing point groups along a surface
a) group of points with the **Allow for borders option disabled**
b) group of points with the **Allow for borders option enabled**

2.5.3.3.1. Setting grid's center position during construction of a point group using the **By grid around the defined point** method

The grid's center position can be specified using two methods.

Method 1

Specifying parameters U and V of the point of the theoretical face's surface,

Specify the grid's center position by a mouse click on the face or enter the required values of the U and V parameters in percent in the **U Parameter, %** and **V Parameter, %** fields.

For more information on theoretical face surface, see Section 2.5.1.3 on p. 328.

You can also set the grid's center position by moving the "Center" hand of the point group's ghost (see Fig. 2.5.17).

Method 2

Specification of a point object on a chosen face within it. The following may be used as the point object:

- ▼ face vertex;
- ▼ a point in space provided that it is a **directly initial** or **directly derivative** with respect to the specified face¹.

Specify the required point object in the model window.

The **Object** button will be ticked, and the field next to the button will display the object name. This indicates the associative relation of the grid center with the selected object. Due to this relation, the grid center will follow the object in case it changes its position. If necessary, the relation can be disabled by clicking the **Object** button. The tick on the button will disappear, and the field will be cleared.

The grid center may be positioned both within the specified face's contour or outside it. If necessary, theoretical surface of a face will be extended (depends on the face's type). Examples of grid center positioning outside the specified face's contour with different statuses of the **Allow for borders** option can be found in the figure.

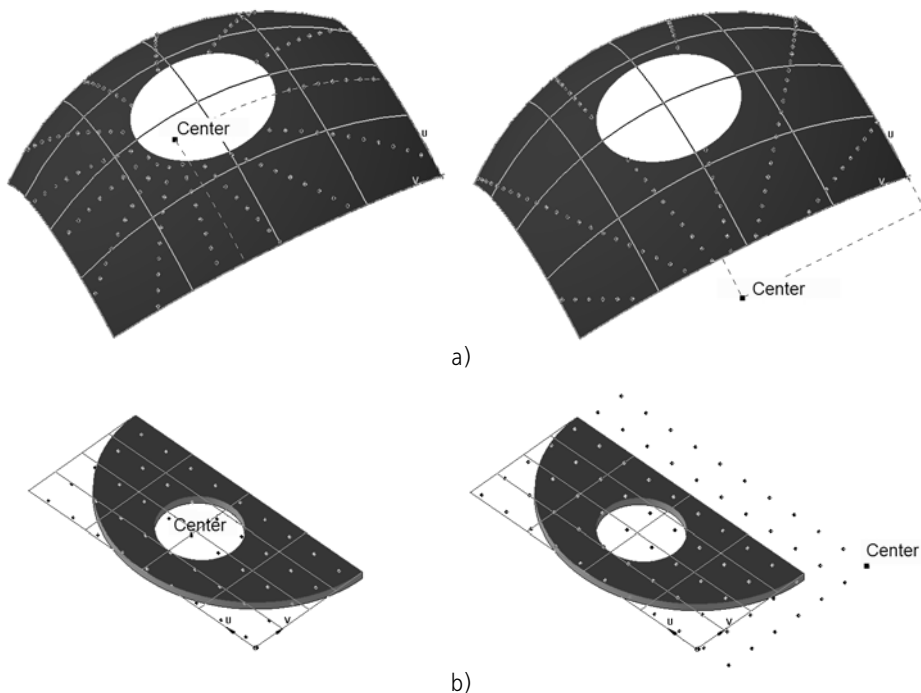

Fig. 2.5.17. Examples of grid center positioning outside the specified face's contour. when constructing point groups along a surface:
a) the **Allow for borders** option is enabled; b) the **Allow for borders** option is disabled

Note that if the grid center transcends the face's theoretic surface limits, it will limit the grid in its movement direction (Fig. 2.5.17, b).

1. In other words, the hierarchy of the relations between the point and the specified face must not contain any other objects (viewing object relations is covered in Section 2.1.2.7.2 on p. 114).

2.5.3.3.2. Setting up grid parameters during construction of a point group using the By grid around the defined point method

The grid's setup includes selection of the grid type and parameter settings.

Three types of grid are available: **rectangular**, **concentric**, and **hexagonal** (Fig. 2.5.15 on p. 355).

Choose the required grid type from the **Grid type** list (Fig. 2.5.18).

Fig. 2.5.18. The **Grid type** drop-down list.

The Property Bar will display controls for setting up the parameters of the grid of the selected type.

Availability of a certain grid type depends on the type of a face to which the group's points should belong.

- ▼ If a **spherical** face is used for construction of a point group, the following grid types are available: **Rectangular** and **Concentric**.
- ▼ If a **cylindric** face is used, the following grid types are available: **Rectangular** and **Hexagonal**.
- ▼ If a **conic**, **toroid**, or **custom** face is used, only the **Rectangular** grid is available.
- ▼ If a **flat** face is used, all grid types are available.

Detailed description of rectangular, concentric, and hexagonal grids is given below in this section.

Before completion of the command the system “remembers” the data entered for every type of grid, so you can switch between grid types without loss of their data.

If necessary, you can rotate the grid around the face's normal in the grid center by a custom angle. Such option is available, if a surface with a constant curvature is selected for construction of a point group (flat face or sphere).

The grid's rotation angle is calculated starting from the U direction counter-clockwise (see Section 2.5.1.3 on p. 328 for more information about the face's parametric representation).

Enter the value of the grid rotation angle in the **Rotation** field. It can either be positive – counter-clockwise rotation, or negative – clockwise rotation.

Rectangular grid

Control elements for setting rectangular grid parameters depends on the type of a face to which the group's points should belong.

- ▼ If a **flat**, **spherical** or **cylindric** face is used, the rectangular grid is characterized in steps along the first axis and along the second axis. The following fields appear on the Property bar: **Step along axis 1** and **Step along axis 2**.

- ▼ If a **conic**, **toroid**, or **custom** face is used, the rectangular grid is characterized by steps in U and V parameters. The following fields appear on the Property bar: **Step along U, %** and **Step along V, %**.

Enter the required grid parameter values in the fields or set them using the counter.

Concentric grid

The concentric grid is characterized by a number of radial rays and grid step in the radial direction. In order to set these parameters, fields in the Property bar are used: **Number of rays** and **Radial step**.

Enter the required grid parameter values in the fields or set them using the counter.

Hexagonal grid

The hexagonal grid is characterized by equal spacing between adjacent grid nodes.

Enter the required step values in the **Step** field or set it using the counter.

2.5.3.4. Point Group from File

To create a point group using the data from a file run the **Point Group from File** command.

The command creates a group of points with the coordinates read from a previously created data file (for more information about the data file, see Chapter VI).

The point parameters can be read from the following file types:

- ▼ Text file;
- ▼ Electronic spreadsheet in Microsoft Excel format;
- ▼ Electronic spreadsheet in Open Office format.

To define the file name click the **Source File** button. The standard Windows Open File dialog will appear on the screen. Select a file and click the **Open** button. The file name will appear in the field.

The values read from a file can be interpreted as rectangular, cylindrical or spherical coordinates.

The interpretation method is selected by means of the switches of the **Coordinate Type** group of the Properties panel.

The group points will be constructed in the coordinate system appropriate for the selected method of data interpretation. The location of that coordinate system relatively to the point coordinate system is detailed in Section 2.5.3.4.1.

2.5.3.4.1. Type of the point's coordinates

Point location can be set in rectangular (X, Y, Z), cylindrical (R, A, Z) or spherical (R, A, B) coordinates. The coordinate system corresponding to the type of coordinates is used to build the point.

Rectangular coordinate system coincides with the point coordinate system.

A cylindrical coordinate system is located relative to the coordinate system of a point in the following way:

- ▼ the cylindrical coordinate system origin coincides with the point coordinate system origin,
 - ▼ Z axis of the cylindrical coordinate system coincides with Z axis of the point coordinate system.
- The A coordinate value defines the point α rotation angle and is counted in the XY plane from the X axis counter clockwise (see Fig. 2.5.19).

Fig. 2.5.19. Creation of a point by cylindrical coordinates; XYZ is the coordinate system of the point

The **spherical** coordinate system origin coincides with the point coordinate system origin.

The A coordinate value defines an azimuth angle α and is counted in the XY plane of the point coordinate system from the X axis counter clockwise (see Fig. 2.5.20). The OA ray is drawn in the XY plane at the azimuth angle to the X axis.

The B coordinate value defines the zenith angle β and is counted from the Z axis in the plane that extends through the Z axis and the OA ray (see Fig. 2.5.20).

Fig. 2.5.20. Construction of a point by spherical coordinates; XYZ is the coordinate system of the point

2.5.3.4.2. Link of Point Group to Source File

The constructed point group remains linked to the source file.

Any modifications of the file will be shown by a red tick on the icon of the point group in the Design Tree.

To eliminate discrepancy between the constructed group and the file content run the **View—Reconstruct Model** command.

The command rearranges the group points according to the new parameter values.

If the source file is deleted or renamed, the point group icon will be marked by the error symbol in the form of an exclamation mark in a red circle in addition to the red tick.

If the point group is constructed with the **Scatter** option on, the built points will not be linked to the source file.

Applying the **Explode** command to the point group eliminates the link of the built points with the source file.

2.5.4. 3D lines

KOMPAS-3D supports creating the following 3D lines:

- ▼ segment,
- ▼ circle's arc,
- ▼ a cylindrical spiral,
- ▼ a conical spiral,
- ▼ polyline,
- ▼ a spline.

You can also import 3D curves saved in a file of the STEP AP203/STEP AP21 or IGES format in the model.

In addition, the program enables trimming curves and creating the following objects:

- ▼ a spline repeating the object form,
- ▼ curve by its two projections,
- ▼ curve that set in the parametric view,
- ▼ rounding of an angle formed by two curves,
- ▼ joining of two curves,
- ▼ Equidistant curve;
- ▼ contour,
- ▼ curves on the surface:
 - ▼ isoparametric curve,
 - ▼ group of isoparametric curves on the surface,
 - ▼ face outline line.
- ▼ spline on surface,
- ▼ projection curve,
- ▼ Intersectional curve of surfaces.

Commands for creating 3D lines and points are located in **Operations** menu, and the buttons to call them are on the **3D Lines** panel (Fig. 2.5.21).

Fig. 2.5.21. **3D Curves** bar

The lines created can be used, e.g. as directing curves when creating swept features of corresponding form.

The model may create the so-called *curves from nowhere*. Such object emerge as a result of exploding arrays of certain data types (see Section 2.7.1.3.7 on p. 517).

2.5.4.1. Curve Display Parameters

Curve display parameters are vertex display style and line style. These parameters can be viewed and edited on the **Properties** tab of the Properties bar (Fig. 2.5.22).

Fig. 2.5.22. **Properties** Tab

The **Vertex Display** button controls the way 3D line vertices are displayed. If the button is pressed, list of **Vertex Styles** is available on the Property bar. You can select a vertex display style from this list.

Once the curve is constructed, its vertices will be displayed in the selected style.

For polylines with filleted vertices the end points of fillets are also marked (Fig. 2.5.23).

Fig. 2.5.23. Display of Polyline Fillet End Points

Vertices displaying button is available during creation of new curves in KOMPAS-3D, Ver. 9 and higher.

By default 3D line are visualized using a line with the *Basic* style applied. To change the current style use the **Line Style** list. The list contains the system styles of lines.

The parameters of current 3D line visualization set during its construction will be applied while creating further 3D curves until the end of the work session.

If necessary, line thickness can be changed by the user. To do this use command **Service — Parameters— System — Model Editor — System Lines**. A dialog will be displayed, in which you can set the required thickness settings.

2.5.4.2. Imported curve

To import a 3D curve (or 3D curves) into a KOMPAS-3D model file the following files may be used:

- ▼ file with the *igs*, *step* or *stp* extension – the curves from this file will be inserted into the current model,
- ▼ data file with *xls*, *ods*, *txt* or *csv* extension (for more information about the data file, see Appendix VI) – the curve will be built in the current model using the coordinates from the file.

The **Imported curve** command is used for the import operation.

After calling the command, a standard **Select file for opening** dialog appears, where you need to select the desired file.

The *igs*, *step* or *stp* file is analyzed for the presence of any 3D curves in it. If no 3D curves are identified in the file, the respective pop-up message will appear on the screen, while the file selection dialog will remain enabled.

After clicking the **Cancel** button in the dialog, the command finishes its operation without saving changes.

If there are curves in the source file, that form a chain, the prompt for unification of the curves will appear during the file reading. An affirmative answer implies that the curves will be unified wherever possible.

Once the import has been finished, icon of the imported curve or several icons of imported curves will appear in the Design Tree. The imported curves are “curves without history”.

Importing curves from files with *igs*, *step* and *stp* extensions has peculiarities described in Section 11.1.2.1.1 on p. 2006.

The coordinate system of the imported curve or curves will be the current coordinate system – absolute or local (see Section 2.8.3.3 on p. 597 for more details about selection of the current coordinate system).

If the coordinate system of an imported curve is not absolute but local, then you can change the position of the imported surface in the model by changing the position of the local coordinate system relative to the absolute coordinate system.

For detailed description of coordinate systems of objects, refer to Section 2.8.3.4 on p. 597.

2.5.4.3. Line segment

You can draw a section in space by the following methods:

- ▼ **By 2 Points,**
- ▼ **By point, length, and inclination angle method.**

In order to create a line segment, the **Line segment** command is used.

Upon calling the command, the construction controls appear on the Property bar (Fig. 48.4).

Fig. 2.5.24. Property bar when creating a line segment

Select an option of line segment construction from the **Method** list or using commands of the context menu.

Then specify line segment parameters and objects used for construction.

After all required data are specified, a ghost of the line segment appears on the screen. Until construction is finished, you can change the line segment parameters by activating the required control element on the Property Bar.

To change objects used for the line segment construction, click **Reselect** button on the Special Control Panel and re-select objects.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the line segment, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361). This tab also shows the name of the line segment coordinate system name (object coordinate system is detailed in Section 2.8.3.4.1 on p. 598).

To finish the construction click the **Create object** button on the Advanced Control Panel.

All methods of line segment creation provide for automatic creation activated by default. For more information on automatic and manual creation of objects refer to Section 1.4.2.10 on p. 93.

2.5.4.3.1. Construction using 2 points

The **By 2 points** method makes it possible to build a line segment by specifying the starting and the ending vertex successively.

To create a line segment, complete the following steps.

1. Set the vertex of the segment. The **Starting vertex** switch will be enabled by default. There are several methods to set up a vertex.

- ▼ Setting the vertex coordinates in space or linking it to an existing point object. Specifying of point coordinates and linking the point to a point object are similar to the procedures used during point creation by the **By Coordinates** method (see Section 2.5.2.2 on p. 336).

- ▼ Creating a segment vertex using the methods of point construction provided by the **Point** command. For this purpose, click the **Point construction** button on the Special Control Panel. The detailed information on point construction is given in Section 2.5.2.1 on p. 334.

After setting the segment's starting vertex, the **Ending vertex** switch will become enabled automatically.

2. Set the ending vertex of the segment. The segment's ending vertex is specified in save way as the starting vertex.

2.5.4.3.2. Construction by point, length, and inclination angle

By point, length, and inclination angle is the method of the segment construction with specification of the segment's plane and setting the following parameters: starting vertex, length, and inclination angle of the segment.

The plane of the segment is parallel to a **base plane**. The following can be used as a base plane:

- ▼ Coordinate or auxiliary plane
- ▼ Planar face;
- ▼ Sketch plane

To create a line segment, complete the following steps.

1. Set the vertex of the segment. The **Starting vertex** switch will be enabled by default. There are several methods to set up a vertex.

- ▼ Setting the vertex coordinates in space or linking it to an existing point object. Specifying of point coordinates and linking the point to a point object are similar to the procedures used during point creation by the **By Coordinates** method (see Section 2.5.2.2 on p. 336).

- ▼ Creating a segment vertex using the methods of point construction provided by the **Point** command. The **Point construction** button is located on the Special Control Panel. The detailed information on point construction is given in Section 2.5.2.1 on p. 334.

By default, the base plane is the one of the coordinate planes. The base plane is selected automatically by the system depending on the model position with respect to the screen plane. The name of the selected coordinate plane is shown in the **Base Plane** field.

After selecting the starting vertex, the segment plane position is automatically defined: by specified point and base plane. The segment's ghost will be displayed.

If necessary, you can select another base plane. To do this, enable the **Base Plane** switch on the Property bar or call the command from the context menu, and select the required object in the Design Tree or the model window (a sketch must be selected in the Design Tree).

You may start the segment construction by defining a base plane: activate the **Base plane** switch, select the required object, then define the starting vertex.

After setting the segment's starting vertex, the **Ending vertex** switch will become enabled automatically.

2. Set the ending vertex of the segment. There are several methods to set up the ending vertex:
 - ▼ setting by the mouse in the model window or linking it to a point object (see Section 2.5.2.2 on p. 336);
 - ▼ setting the segment's length or inclination level in the base plane.
Set the segment's length.

The segment's length can be entered from the keyboard. You can also specify the point's position using the mouse in the model window. In this case, the segment's inclination angle is defined automatically.

Set value of the segment's inclination angle.

The angle of the segment's inclination is counted off from the abscissa axis of coordinate system of the base plane. The angle's value can be entered from the keyboard. You can also specify the point's position using the mouse in the model window.

If the ending vertex has an associative link to a point object, the **Length and Angle** fields will not be available for editing.

2.5.4.4. Circular Arc

You can construct a circular arc in space by the following methods:

- ▼ **By 3 Points,**
- ▼ **By Center and Radius,**
- ▼ **By 2 Points with Direction,**
- ▼ **Tangent to Curve.**

To create a circular arc in space, call the **Circular Arc** command.

Select an option of point construction from the **Method** list or using commands of the context menu. The elements for managing construction will appear on the Properties Bar (Fig. 2.5.25).

Fig. 2.5.25. Property Bar in case of circular arc creation by 3 points

Then specify arc parameters and objects used for construction.

After specifying one of the arc parameters, you will automatically transfer to the next parameter.

Points are the construction objects in all methods. The following ways may be used to define an arc point:

- ▼ specify coordinates in space or select the point's position by mouse in the model window;
- ▼ link to an existing point object;
- ▼ create a point using the point creation methods of the **Point** command without leaving the arc creation process (see Section 2.5.2.11 on p. 346).

Selecting of the point object when the **Associate** option is on will result in creation of associative relation of the point with this object.

The presence of relation is manifested by displaying a checkmark on the **Object** button and the name of the point object in the **Object** field on the Property Bar. In case of any change of the object position, the arc point will follow the object.

To cancel the associative relation with the point object, click the **Object** button. The tick on the button will disappear.

To restore an associative relation of a point and a point object, enable the **Auto association** option and specify the required object anew.

Parameter input and object specification for each method is detailed in Sections 2.5.4.4.1–2.5.4.4.4.

Point coordinates are specified in the arc coordinate system (for object coordinate system, refer to Section 2.8.3.4 on p. 597).

After all required data are specified, a ghost of circular arc appears on the screen. Until construction is finished, you can change the arc parameters by activating the required control element on the Property Bar.

If required you may construct a circle. To do this, enable the **Circle** switch in the **Arc** group. It is possible for all methods of arc construction.

Before completion of the command, the system “remembers” the parameters and objects specified in each construction method, therefore you can switch between the methods without loss of these data.

To change the objects used for arc construction by the selected method, click the **Select Other** button on the Special Control Panel and repeat selection of objects.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the arc, set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361). This tab also shows the name of the arc coordinate system name (object coordinate system is detailed in Section 2.8.3.4.1 on p. 598).

To finalize the construction, click the **Create Object** button on the Special Control Panel.

All methods of circular arc creation provide for automatic creation activated by default. For more information on automatic and manual creation of objects refer to Section 1.4.2.10 on p. 93.

2.5.4.4.1. Creation by 3 Points

By 3 points is a method of circular arc creation by three points.

To create a circular arc by this method, specify arc start point **1**, then arc end point **2** and intermediate point **3** on the arc. After selecting point **1**, a circle ghost will appear on the screen, after selecting point **2**, an arc ghost will appear. After specifying intermediate point **3**, the arc is defined completely.

- ▼ You can select an arc point by setting its coordinates in space or linking it to an existing point object. Specifying of point coordinates and linking the point to a point object are similar to the procedures used during point creation by the **By Coordinates** method (see Section 2.5.2.2 on p. 336).
- ▼ You can specify an arc point by creating it. In this case, use the point creation methods of the **Point** command. See Section 2.5.2.1 on p. 334 for details.

By default, a circular arc passes from point **1** to point **2** through point **3**. In this case, the **Default Arc** switch is active. To create a supplementary arc (that does not pass through point **3**) or a circle, enable the required switch.

2.5.4.4.2. Creation by Center and Radius

By Center and Radius is a method of circular arc creation by specifying its plane and parameters: center of the arc, starting and ending angles, radius.

The plane of a circular arc is parallel to a **base plane**. The following can be used as a base plane:

- ▼ Coordinate or auxiliary plane
- ▼ Planar face;
- ▼ Sketch plane

To construct an arc, do the following.

1. Select centerpoint **1** of the arc.
- ▼ You can select an arc point by setting its coordinates in space or linking it to an existing point object. Specifying of point coordinates and linking the point to a point object are similar to the procedures used during point creation by the **By Coordinates** method (see Section 2.5.2.2 on p. 336).
 - ▼ You can specify an arc point by creating it. In this case, use the point creation methods of the **Point** command. See Section 2.5.2.1 on p. 334 for details.

By default, the base plane is the one of the coordinate planes. The base plane is selected automatically by the system depending on the model position with respect to the screen plane. The name of the selected coordinate plane is shown in the **Base Plane** field.

If necessary, you can select another base plane. To do this, enable the **Base Plane** switch and select the required object in the Design Tree or the model window (a sketch must be selected in the Design Tree).

You may start the arc construction by defining a base plane: activate the **Base plane** switch, select the required object, then define point **1**.

After selecting point **1**, the arc plane position is automatically defined: by specified centerpoint and base plane. A ghost of an arc circle with centerpoint **1** will appear on the screen.

2. Enter the arc radius/diameter. By default the system waits for the radius to be entered. In this case, the **Radius** switch is active in the **Parameter** group. To enter the diameter, activate the **Diameter** switch. A ghost of a circle with the specified dimension will appear on the screen.

3. Select the arc start point **2** by specifying a start angle of the arc. The start angle is counted from the abscissa axis of the base plane's coordinate system. You can enter an angle value from keyboard or link the arc start point to an existing point object. A ghost of an arc with the specified start angle will appear on the screen.

4. Select the arc point **3** by specifying the end angle. The end angle is specified in the same way as the start angle.

After performing the above steps, the arc is defined completely: arc plane position, center point, start and end angles, radius are specified.

By default, a circular arc is created clockwise from point **2** to point **3**. In this case, the **Default Arc** switch is active. To create a supplementary arc or a circle, enable the required switch.

In case of creation of a complete circular arc, after selecting point **1**, the system immediately proceeds to specifying radius (point **4**).

2.5.4.4.3. Creation by 2 Points with Direction

By 2 Points with Direction is a method of circular arc creation by two points with specifying a direction of a tangent vector in one of them. The direction of a tangent vector is selected by means of a vector or guide objects. The following objects can be used as guide objects.

▼ Straight object:

- ▼ line segment of a sketch,
- ▼ polyline segment,
- ▼ coordinate or auxiliary axis,
- ▼ straight line edge.

Direction, defined by a straight object — a line parallel to the object.

▼ Planar object:

- ▼ coordinate or auxiliary plane,
- ▼ planar face,
- ▼ Sketch plane

Direction, defined by a plane object — a line perpendicular to the object.

▼ Curve (if the start point or the end point of the arc belongs to this curve).

The direction defined by the curve is tangent vector in the point of tangency. Thus, you may construct an arc mated with an arbitrary curve: 3D spline or polyline, edge etc.

To construct an arc, do the following.

1. Specify start point **1** of the arc.
 - ▼ You can select an arc point by setting its coordinates in space or linking it to an existing point object. Specifying of point coordinates and linking the point to a point object are similar to the procedures used during point creation by the **By Coordinates** method (see Section 2.5.2.2 on p. 336).
 - ▼ You can specify an arc point by creating it. In this case, use the point creation methods of the **Point** command. See Section 2.5.2.1 on p. 334 for details.

2. Select end point **2** of the arc. Specify point **2** in a similar way as point **1**. After specifying point **2**, the system will proceed to the selection of direction for this point: the **Direction in Point** switch corresponding to point **2** will be enabled.

3. Specify the direction. To do this, select the appropriate guide object in the Design Tree or in the model window (a sketch must be selected in the Design Tree) or build a vector (see Section 2.8.5 on p. 613).

To build a vector click the **Construction of Vector**. This button is located on the Advanced Control panel.

The name of the selected object will be displayed in the **Direction in Point** field. If the direction is set by means of a vector, the field will contain the word "Vector".

A ghost of the arc with points **1**, **2** and a tangent vector in point **2** showing the specified direction will appear on the screen.

For the arc mated with a curve, you must specify the point on this curve: the start point, the end point or the point created by **On Curve** or **On Intersection** methods (see Section 2.5.2.1 on p. 334), and the curve itself as a guide object in this point.

The direction may be specified only in one point of the arc, i.e. start point or end point. That is why if the direction in one of this points has already been specified, the selection of the object for the first point should be canceled after specifying the direction in the other point.

After specifying points **1**, **2** and selecting the direction, the arc is defined completely: the system creates the arc plane and calculates the position of the center point and the radius.

The arc plane is created by a straight object and a point. A tangent vector is used as a straight object.

The center point C of the arc lies on the intersection of the axis c and perpendicular bisector m to the segment connecting points **1** and **2** (Fig.2.5.26). Axis c is perpendicular to the vector of direction in the point.

Radius is defined as the distance between the centerpoint C and the point **1**.

Fig. 2.5.26. Specifying centerpoint and radius

By default, a circular arc runs from point **1** to point **2** in the direction similar to the direction of a tangent vector. In this case, the **Default Arc** switch is active. To create a supplementary arc or a circle, enable the required switch.

2.5.4.4.4. Creation of Arc Tangent to Curve

Tangent to Curve is a method of circular arc creation by specifying a curve the arc circle should be tangent to, and the arc parameters: the center, starting and ending angles.

The following may be used as a curve:

- ▼ coordinate or auxiliary axis,
- ▼ a 3D curve,
- ▼ sketch lines,
- ▼ edge.

To construct an arc, do the following.

1. Select the curve the arc circle should be tangent to. To do this, select the desired object in the Design Tree or in the model window. The selected object's name will be displayed in the **Curve** field. A ghost of a circle tangent to the specified curve will appear on the screen.
2. Select centerpoint **1** of the arc.
 - ▼ You can select an arc point by setting its coordinates in space or linking it to an existing point object. Specifying of point coordinates and linking the point to a point object are similar to the procedures used during point creation by the **By Coordinates** method (see Section 2.5.2.2 on p. 336).
 - ▼ You can specify an arc point by creating it. In this case, use the point creation methods of the **Point** command. See Section 2.5.2.1 on p. 334 for details.

After specifying point **1**, specify the location of arc plane and radius (point **4**).

The plane is created by a point and a straight object. A straight object is a tangent line passing through the point of a specified curve that is closest to the centerpoint of the arc.

The calculated value of radius is displayed in the **Radius** field. If required, you can enter a desired radius value into this field. The system will calculate the new position of centerpoint **1**.

If the point **1** is associatively related to a point object, then the value in the **Radius** field cannot be changed.

You can use a circle diameter to create an arc. To do this, enable the **Diameter** switch in the **Parameter** group.

3. Select the arc start point **2** by specifying a start angle of the arc. The start angle is counted from the ray directed from the center of the arc to the tangency point. You can enter an angle value from keyboard or link the arc start point to an existing point object. A ghost of an arc with specified start angle and point **4** will appear on the screen.
4. Select the arc point **3** by specifying the end angle. The end angle is specified in the same way as the start angle. A ghost of the arc with specified points **1, 2, 3, 4** appears on the screen.

If points **2** and **3** are associatively related to point objects, then the fields for entering angle values are not accessible, they show angle values calculated by the system.

After performing the above steps, the arc is defined completely: arc plane position, center point, start and end angles, radius are specified.

By default, a circular arc is created clockwise from point **2** to point **3**. In this case, the **Default Arc** switch is active. To create a supplementary arc or a circle, enable the required switch.

In case of creation of a complete arc, after specifying point **1**, a circular arc is defined completely: the **Create Object** button on the Special Control Panel becomes accessible.

2.5.4.5. Spirals. General construction methods

Spiral construction commands are accessible if some planar object is selected in a model window: an auxiliary or projection plane, flat face of a part. This item is a reference object for a spiral.

After any of commands to construct a spiral is applied you must specify its parameters in the fields on the Property bar.

All the parameters are displayed on the screen as a ghost of a spiral.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the spiral, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361).

To fix this spiral in the model, click the **Create Object** button on the Special Control Panel.

The created spiral will appear in the model window, and the spiral's icon will appear in the Design Tree.

2.5.4.6. Cylindrical Spiral

To create a cylindrical spiral, apply the **Cylindrical Spiral** command.

2.5.4.6.1. Construction Method

Select the method for spiral creation: **By Pitch and Number of Revolutions**, **By number of Revolutions and Height** or **By Pitch and Height** selecting it from the **Construction Method** list.

2.5.4.6.2. Number of revolutions, pitch, height

Enter the number of revolutions of the spiral in the **Number of Revolutions** field. Number of revolutions can be non-integral. If the spiral construction method **By Pitch and Height** is selected, then **Number of Revolutions** field becomes inaccessible for value input and it displays the calculated number of revolutions.

Enter a pitch of spiral in the **Pitch** field. If the spiral construction method **By Number of Revolutions and Height** is selected, then the **Pitch** field is inaccessible for data input and it displays the calculated value of the pitch.

If the spiral construction method **By Pitch and Height** or **By Number of Revolutions and Height** is selected, the group of options **Height** for setting the spiral height becomes accessible.

By Value method

The height of spiral equals the value specified in the **Dimension** field.

Activate the **By Value** switch in the **Height** group and enter the spiral height into the **Dimension** field.

By Object method

The height of the spiral is automatically determined by location of the object specified by a user (an edge or a point in the model window).

Activate the **By Object** switch in the **Height** group and specify vertex, face, plane or surface in the model window. The name of the object will be displayed in the **Object** reference field.

Enter the required distance between the element's end plane and the object in the **Dimension** field

In order to draw a spiral exactly to the vertex or the surface, enter a zero value.

If the distance to an object exceeds the zero value, it can be applied both in the direction of spiral construction (in this case, the spiral will be extended "off" the object for the distance specified), and against the direction of spiral construction (in this case, the spiral won't reach the object for the distance specified). To specify direction of measuring the distance to the vertex, activate the **Before Object** or **Behind...** switch in the **Type** group.

By Flat Curve method

Spiral's height is defined automatically by the length of the indicated sketch line (spiral has the same form as the line while the spiral axis is a cop of the line resulting from the parallel transfer of the sketch line where its initial point matches the spiral's anchor point. The plane of used sketch must be perpendicular to the base face of the spiral.

Activate the **By Flat Curve** switch in the **Height** group and select the required sketch line in the model window.

The object name will be displayed in the reference field beside the **Object** switch.

If sketch plane and spiral axis plane are not parallel, spiral will automatically rotate so that these planes become parallel.

2.5.4.6.3. Direction

By default, a spiral will be constructed outwards in relation to the base face. This is **Straight Direction**. To direct the spiral to the other direction, activate the **Reverse Direction** switch in the **Direction to Construct** group.

If the spiral height is defined by object or sketch line, then changing of the spiral construction direction is impossible (**the Direction to Construct** group is inaccessible).

2.5.4.6.4. Direction of Coiling

Select the direction of the spiral's coiling — **Right** or **Left**.

To do this, activate the relevant switch in the **Direction of Coiling** group.

2.5.4.6.5. Starting Angle

Enter the start angle of the spiral in the **Angle** field. It is the spiral rotation angle around the perpendicular to the reference surface.

The angle is measured in relation to the abscise axis of the base face's coordinate system.

2.5.4.6.6. Spiral diameter

Options to control the spiral's diameter are located on the Properties Bar's **Diameter** tab.

Select a method to define the spiral diameter. For this, you should activate the corresponding switch in the **Diameter** group (see Table). 2.5.5).

Tab. 2.5.5. Methods to define the diameter of a cylindrical spiral

	Value of Option	Procedure of defining the spiral's diameter. Work sequence
	By Value	Diameter of a spiral is equal to the value specified by a user. To select this variant enter the spiral's diameter into the Diameter 1 field.
	By Object	The diameter of the spiral is automatically defined by size or by location of the object specified by a user (see below). To select this variant, specify in the model window the object to define the spiral's diameter. The object name will be displayed in the Object 1 reference field, and the Diameter 1 field will read the calculated value of the diameter.

Object to Define Spiral Diameter

- ▼ A point can be selected as the object (a part vertex, a coordinate system origin, a line end or a point in a sketch, etc.). In this case, the spiral diameter is assumed to be equal to the distance from the spiral center to the projection of the specified point on the spiral's base plane.
- ▼ You can select a part edge or sketched image having the shape of a circle or arc, as the object. In this case, the spiral diameter is assumed to be equal to the diameter of the selected arc or circle.

2.5.4.6.7. Spiral Location

The cylindrical spiral ghost with the specified parameters will appear in the model window. Spiral Anchor Point by default is located at the coordinate system origin of a face or plane, on which the spiral is created.

To place the spiral in the desired position on a face or plane, unfix the **t** field on the **Property Bar**. Select the spiral position with the mouse or enter the spiral center coordinates in the **t** field.

Once the spiral's construction in the model has been finished, aside from the spiral itself, a sketch containing one object (the spiral's anchor point) is also created. That sketch is located on the plane or flat face selected for a spiral construction. If required, you can control the position of an already created spiral by changing the position of the point in the sketch (see Section 2.14.3.5.1 on p. 791).

2.5.4.7. Conical Spiral

To create a conical spiral, enable the **Conical Spiral** command.

Construction method, number of revolutions, pitch, height, direction of coiling and construction of a conical spiral are to be set in the same way as for a cylindrical spiral (see Sections 2.5.4.6.1–2.5.4.6.5).

A conical spiral differs from a cylindrical one by presumption that its initial diameter won't be equal to the final diameter and the spiral height definition using a flat curve is not accessible.

Options to manage the initial and final diameters are located on Properties Bar's **Diameter** tab.

2.5.4.7.1. Initial and Final Diameters

Select a method to set the spiral's initial and final diameters. For this, activate the corresponding switch in the **Start Diameter** and **Final Diameter** groups (see Table 2.5.6).

Tab. 2.5.6. Methods to set the initial diameter for a conical spiral

Option value	Procedure of defining the diameter.
Starting Diameter (Ending Diameter)	Work sequence
By Value	Diameter is equal to the value specified by user. To select this variant, enter the initial (final) diameter of the spiral in the Diameter 1 (Diameter 2) field.

Tab. 2.5.6. Methods to set the initial diameter for a conical spiral

	Option value	Procedure of defining the diameter. Work sequence
 	By Object The diameter is automatically defined by the size or position of the object specified by a user (for the object defining the spiral's diameter — see p. 473). To select this variant, specify the object required in the model window. The object name will be displayed in the Object 1 (Object2) reference field, and the Diameter 1 (Diameter 2) field will read the calculated value of the diameter.	
	By Slope of Generating Line* The final diameter is calculated by the specified values of the initial diameter and the slope of the conical spiral's generating line. To select this variant, enter in the Angle field the value of the generating line's slope to the spiral axis. Select direction of the generating line's slope by enabling the corresponding switch in the Slope of Generating Line group (see Table 2.5.7). The calculated value of the final diameter will appear in the Diameter 2 field.	

* For final diameter only

Tab. 2.5.7. Slope direction of conical spiral generatrix

	Value of option	Construction result
	Outside	The spiral diameter is increasing along the construction direction.
	Inside	The spiral diameter is decreasing along the construction direction.

2.5.4.7.2. Spiral Location

The conic spiral ghost with the specified parameters will appear in the model window. Spiral Anchor Point by default is located at the coordinate system origin of a face or plane, on which the spiral is created.

To place the spiral in the desired position on a face or plane, unfix the **t** field on the **Property Bar**. Select the spiral position with the mouse or enter the spiral center coordinates in the **t** field.

2.5.4.8. 3D Splines and Polylines General construction methods

3D polyline and spline are pointwise set curves. The points defining these curves are referred to as **vertices**.

A 3D polyline consists of lines that consequently connect the specified vertices. You can round vertices of a polyline by circle arcs.

A spatial spline is defined by the set of vertices and its order. The spline shape depends on the position of the defined vertices in space. Depending on the type a spline may go directly through the specified vertices or at a distance from them. The distance to each vertex depends on its weight.

For details on curve order and point weight refer to Section 2.5.1.4 on p. 329.

After running the curve construction command set the parameters of its vertices.

A polyline vertex can be constructed as follows:

- ▼ **By points** (see section 2.5.4.8.3 on p. 379);
- ▼ **By Axes** (see Section 2.5.4.8.4 on p. 381);
- ▼ **By Objects** (see Section 2.5.4.8.5 on p. 383).

You can do any of the following to define a vertex coordinates:

- ▼ entering coordinate values into the parameter table of polyline vertices (see Section 2.5.4.8.1 on p. 376),
- ▼ creating a special point (see Section 2.5.2.11 on p. 346),
- ▼ linking a vertex to a reference point (see Section 2.5.4.8.6 on p. 384).

While each vertex is constructed, the line connecting it to the previous one – the **vertex construction line** – is being displayed.

2.5.4.8.1. Vertex Parameter Table

Every vertex of a polyline or a spline is characterized by a set of parameters. Their values are displayed in the Table of Vertices (Fig. 2.5.27).

This table is called **Vertices Coordinates** and is located on the Properties Bar's **Parameters** tab.

Every vertex is specified by a table row.

The following parameters are common for all the spline and polyline:

- ▼ Vertex number,
- ▼ 3D coordinates of the vertex;
- ▼ Relation mark is the vertex is associated with a point object;
- ▼ Relation and vertex marks if the vertex was created using the **Point** command (see Section 2.5.2.11 on p. 346) by any method, except for the **By coordinates (XYZ)** method.

The specific parameters are the following:

- ▼ for a polyline — vertex rounding radius (see Section 2.5.4.10.2 on p. 398);
- ▼ for a spline (when creating a spline by poles; see Section 2.5.4.9.1 on p. 387):
 - ▼ weight;

- ▼ relation icon and system pole icon (for more about system pole see Section 2.5.4.9.3 on p. 389).

N	<input type="checkbox"/>	X	Y	Z	Weight
1	<input checked="" type="checkbox"/>	88.0	-73.0	-16.0	1.0
2	<input checked="" type="checkbox"/>	55.0	-58.0	4.0	1.0
3	<input checked="" type="checkbox"/>	0.0	0.0	0.0	1.0
4	<input checked="" type="checkbox"/>	-63.0	77.0	-14.0	1.0
5	<input checked="" type="checkbox"/>	-45.0	35.0	10.0	1.0
6	<input checked="" type="checkbox"/>	-74.0	57.0	17.0	1.0
7	<input type="checkbox"/>	-79.0	83.0	-4.0	1.0

a)

N	<input type="checkbox"/>	X	Y	Z	Radius
2	<input checked="" type="checkbox"/>	-6.0	-40.0	-63.0	0.0
3	<input type="checkbox"/>	100.0	-40.0	-63.0	10.0
4	<input checked="" type="checkbox"/>	100.0	-40.0	-41.0	10.0
5	<input type="checkbox"/>	100.0	-8.0	-41.0	10.0
6	<input checked="" type="checkbox"/>	80.0	20.0	22.0	10.0
7	<input checked="" type="checkbox"/>	100.0	24.0	26.0	0.0

b)

Fig. 2.5.27. Table of Vertices' Parameters a) spline, b) polyline

The table rows are formed automatically during vertex construction in the model window. At the same time, creating or editing the table row shall involve creation of a new table or will change the parameters for the current curve vertex.

Curve vertex coordinates are specified in curve's coordinate system (for object coordinate system, refer to Section 2.8.3.4.1 on p. 598).

A detailed description on methods of operation with the table of vertex parameters is provided in Section 2.5.4.8.2 on p. 377.

2.5.4.8.2. Methods of operation with the table of parameters

Vertex parameter table controls and table context menu commands allow the following manipulations:

- ▼ replacing the entries in all cells of the selected column with the zero value or value from the first cell;
- ▼ fill in the table with a set of values from an external text file;
- ▼ save the contents of the parameters table into a text file for a future reuse;
- ▼ create new vertices;
- ▼ modify parameter values of existing vertices in the table;
- ▼ delete the curve's vertices;
- ▼ Allows deleting the connection of a vertex to a point object;
- ▼ Cancel spline mating with the model object.

The entries in all cells of the selected column replacing

To select a column, click its header by the mouse. You can also pick a cell by the mouse, which belongs to the column to be selected, and call the context menu **Select Column** command.

The **Set Value to Zero** command available in the table's context menu allows replacing the entries of all cells of the selected column with the value *0.0*.

The **Copy Value by 1st Cell** command available in the table's context menu allows replacing the entries of all cells of the selected column with the value entered in the first cell.

The **Copy Value by 1st Cell** command is available if the curve does not contain vertices related with point objects.

Reading the vertices file

While constructing a spline or a polyline you can set the vertex parameters using the data previously saved in a file. For more information about the data file, see Chapter VI.

To construct a curve using data from a file saved on the disk click the **Read from File** button. Select the required file in the Open A File standard dialog on the screen. Table of parameters shall be filled in with the data from this file. The ghost of the polyline constructed by the table data will appear in the Model window.

The **Read from File** button is accessible only when a spline parameters table is empty.

Saving Vertex Parameters to File

To save the vertices parameters into a file you should click the **Save to File** button.

The standard Windows save file dialog will appear on the screen. In this dialog you need select a file name and the directory to save. By default the file shall be assigned the *txt* extension.

Coordinates can be saved into text file only if at least one row is filled in the parameter table.

Creating a new vertex in the parameters table

To create a vertex before an existing one, select the line with this vertex ID and click the **Create New Vertex** button or the *<Insert>* key.

In the model window a new vertex shall appear. Its ID number will be equal to the number of the current vertex. Numbers of vertices starting from the one before which the new one was inserted will be increased by one. Parameter values of the created vertex will be the same as those of the vertex before which it is inserted. The newly created a vertex parameters line will be active.

Changing of the vertex parameters in the table of parameters

To change the curve vertex parameter, activate the desired cell of parameters table by double clicking the mouse and enter the new value to it. To move between cells, use arrow keys.

Coordinates can be entered only for the vertices of a curve constructed using the **By Point** method and not related to a point object.

Deleting Vertices from the Table

To delete a vertex, select the row to be deleted and click the **Delete Vertex** button or press the <Delete> key.

Using the <Shift>+ <arrow> keys, you can select several rows and delete them at once.

Deleting a relation between a vertex and a point object

To delete the relation of a vertex with the point or point object constructed for it highlight the necessary row in the table and click on the relation mark for the vertex in the **Relation** column or run the **Delete Relation** command from the table context menu. The relation will be deleted, the vertex coordinates won't be changed.

Be careful when deleting a relation, since this action cannot be undone. To restore the relation you should edit the vertex by recreating or specifying the required point.

Canceling spline mating with the model object

If the spline vertex has the attribute of a system pole, the spline mating can be deleted by canceling the attribute (mating splines is detailed in Section 2.5.4.9.2 on p. 388). To cancel spline mating highlight the system pole row underlying the mating in the table, click on the system pole mark in the **Relation** column or run the **Delete Relation** command from the table context menu. The mating will be cancelled whereas the system pole attribute will be dissociated from the vertex. The vertex coordinates will remain unchanged.

Be careful when deleting a mating, since this action cannot be undone. You will have to redo the mating in order to restore it.

2.5.4.8.3. Construction by Point

To construct a spline or polyline vertex by points select option **By Points** from the **Construction Method** drop-down menu.

The following methods can be applied to define vertex coordinates:

- ▼ Picking a vertex position by the cursor in the Model window,
- ▼ Linking the vertex to a point object;
- ▼ Construction of a special point;
- ▼ Inputting data in Table of Vertex Parameters cells,
- ▼ Reading parameter values from the vertex parameter file;

Selection of the vertex by cursor and linking the vertex with the point object are covered further in this section. The use of vertices table and reading the contents of the vertex parameter from a file are described in Section 2.5.4.8.1 on p. 376 whereas point construction is covered in Section 2.5.2.11 on p. 346.

Specifying vertex position in the Model window

The position of a polyline or spline vertex can be defined by cursor in the Model window. In this case, the vertex coordinates will be defined by:

- ▼ The cursor position on the screen plane;
- ▼ The screen plane orientation in the model space;
- ▼ Constraints (fixes), which might restrict coordinate modifications.

To fix a coordinate value, use the switch located beside this coordinate input field. By default the coordinate is non-fixed. For this purpose, the switch has a checkmark. To fix a coordinate value, you can do the following:

- ▼ Click the switch;
- ▼ Press <Enter> when the cursor is in the coordinate input field.

After fixing the coordinate value, the mark on the switch will be a “cross”.

To finish building the polyline vertex click in the Model window or fix all of the three vertex coordinates.

A new vertex will appear in the Model window. Its parameters line will be added to the Vertices Parameters Table.

After that, the system will be waiting for another vertex to be selected.

The state of a coordinate value being fixed is maintained only when inputting the current vertex coordinates. After creating it, the coordinate will be unfixed.

While constructing a polyline you can create several successive points with the same value of one of the coordinates (for example, when creating vertices in the same plane). For this, do the following.

1. Define and fix the value of the concerned coordinate.
2. Click the **Remember Status** button on the Special Control Panel.
3. Keep selecting the positions of polyline vertices. The fixed status of the coordinate will be preserved.
4. When finished with creating vertices with the same coordinate value, release the **Remember Status** button.

Linking the vertex to a point object

To link the vertex to a point object highlight the necessary point object with the cursor.

To specify a point object, hover the cursor over the object. When the symbolic notation of a line appear next to the cursor, click the left mouse button.

The new vertex will appear in the Model window. The row with its parameters in the Vertex Parameters Table will be automatically filled with the coordinates of the selected point.

If the **Associate** option is on, the vertex is associated with the selected point object (see Section 2.5.4.8.6 on p. 384).

If the curve vertex was created with the **Associate** option off, the curve vertex will coincide with the selected point object, but will not be related to it - i.e. while moving the point object the vertex position will remain unchanged.

2.5.4.8.4. Construction by Axes

Construction of a spline or a polyline by axes is limited by the following restriction to the direction of the vertex line construction: the line is constructed parallel to the selected axis of the polyline coordinate system (object coordinate system is covered in Section 2.8.3.4.1 on p. 598).

To select a coordinate axis, which the polyline segment will be parallel to, use any of the following methods:

- ▼ Select the required variant from the **Construction Method** drop-down list,
- ▼ Call the respective context menu command,
- ▼ Use the coordinate axes displayed next to the created a vertex in the Model window (see Fig. 2.5.28).

Fig. 2.5.28. Specify a coordinate axis in the Model window

For the last instance, the variant, corresponding to the specified direction, is automatically selected from the **Construction Method** drop-down menu. Once the coordinate axis is selected, if you move the screen cursor, the line of vertex construction, parallel to that axis, will be displayed.

The following methods can be used to define the vertex coordinates on the construction line:

- ▼ setting offset of the vertex to be created against the previous surface or a preset surface.
- ▼ Specifying vertex position in the Model window;
- ▼ Linking the vertex to a point object.

After that, the system will be waiting for another vertex to be selected. The direction of the vertex construction line will be saved. To modify it, use the following methods:

- ▼ Select the **By Points** construction method;
- ▼ Select a different coordinate axis;
- ▼ Select the **By Objects** construction method;

Setting offset of the vertex

There are two methods of setting offset for the vertex to be created.

Method 1

Offset of the vertex against another vertex along the construction line is set (**distance** between vertices).

Method 2

Offset of the vertex against the specified face is set. In this case you must select a **base face** and set **offset** from it. The base face may be represented by any face or plane.

In this case, the position of the vertex being created is determined as follows (see Fig. 2.5.29).

1. A surface equidistant to the reference surface and positioned at distance from it.
2. The intersection point for the construction line and equidistant surface is found.
If required, theoretical surface of the face will be prolonged (see Section 2.5.1.3 for more information on the face's theoretical surface).
3. The vertex to be created is mated to the resulting intersection point.

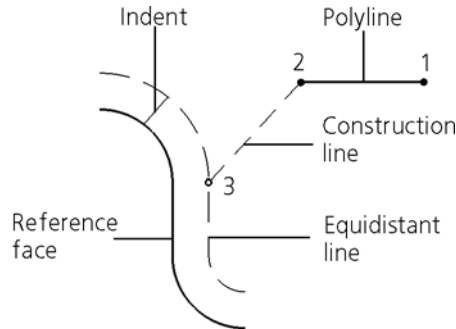

Fig. 2.5.29. Determination of the vertex position by setting its offset against the reference face.

- ▼ To specify the vertex offset using the first method, you should activate the **Offset from the Previous Vertex** switch in the **Offset** group of the Properties bar.

Specify the necessary value in the **Distance** field. Sign preceding the distance value determines the side from the previous vertex on the plotting line on which the current vertex is to be positioned.

- ▼ To specify the vertex offset using the second method, you should activate the **Offset from the Base Surface** switch. The elements for managing vertex offset will appear on the Properties Bar.

To specify a base face, activate the **Base Surface** switch and select the required face in the model window. The selected face is highlighted. The name of the selected object is displayed in a field beside the switch.

Specify the necessary value in the **Offset** field. The sign preceding the offset value determines the side from the reference surface on which the vertex is to be positioned.

The position of the vertex can be set by specifying a point in the model window (see Sections: *Specifying vertex position in the Model window with the Cursor* on p. 383, *Linking the vertex to a point object* on p. 383).

After defining parameters of the offset, press the <Enter> key.

A new vertex will appear in the Model window. Its parameters line will be added to the Vertices Parameters Table.

Specifying vertex position in the Model window with the Cursor

The vertex position of a polyline or spline can be explicitly defined with the cursor in the Model window. In this case the vertex coordinates coincide with the cursor position projection on the vertex construction line.

To build a vertex click in the Model window.

A new vertex will appear in the Model window. Its parameters line will be added to the Vertices Parameters Table.

Linking the vertex to a point object

The vertex of a spline or a polyline created by axes can be linked to a point object. To do this click on the desired point object with the cursor. In this case the curve vertex will coincide with the projection of the selected point object onto the vertex construction line.

To specify a point object hover the cursor over it in the Model window. When the symbolic notation of a line appear next to the cursor, click the left mouse button.

The new vertex will appear in the Model window. The parameters row for the new vertex in the Vertices Parameters Table will be populated automatically. The coordinate value by the selected axis will be the same as the respective coordinate of the selected point object.

If the **Associate** option is on, the vertex is associated with the selected point object (see Section 2.5.4.8.6 on p. 384).

If the curve vertex was created with the **Associate** option off, the curve vertex will coincide with the selected point object (or its projection), but will not be related to it - i.e. while moving the point object the vertex position will remain unchanged.

2.5.4.8.5. Construction by Objects

Construction of a spline or a polyline by objects is limited by the following restriction to the direction of the vertex line construction: To define the line direction, use the existing straight or flat objects in the model window. The vertex construction line may run parallel to a straight object or perpendicular to a straight or flat object.

If the vertex construction line is created parallel to the object, you may employ a vector as a director for such construction line.

A vector may be created with the **Vector drawing** command without leaving the curve construction sequence (see Section 2.8.5 on p. 613).

The following methods can be used to define the vertex coordinates on the construction line:

- ▼ setting offset of the vertex to be created against the previous surface or a preset surface (see Section *Setting offset of the vertex* on p. 381),
- ▼ Specifying the vertex position in the Model window (see Section *Specifying vertex position in the Model window with the Cursor* on p. 383);
- ▼ Linking the vertex to a point object (see Section *Linking the vertex to a point object* on p. 383).

Creating the vertex construction line parallel to the object

The curve vertex construction line may be created parallel to an existing straight object (see Table 2.1.7 on p. 131). Moreover, the object defining the direction of the construction line may

be represented by a vector. This vector can be created with the **Vector drawing** command without leaving the curve construction sequence (see Section 2.8.5 on p. 613).

To create a vertex construction line perform the following operations.

1. From the **Construction Method** drop-down list select the **Parallel to Object** option.
 2. Select the guide object in the window or in the Design Tree or build a vector.
- ▼ To select a guide object in the model window move cursor next to it. When the symbolic notation of the object appears click the left mouse button.
 - ▼ To create a vector defining the direction of the vertex construction line click the **Construction of Vector** on the Advanced Control panel.

Creating the vertex construction line perpendicular to the object

The curve vertex construction line may be created perpendicularly to an existing straight or flat object (see Table 2.1.7 on p. 131).

To create a vertex construction line perform the following operations.

1. From the **Construction Method** drop-down list select the **Perpendicularly to Object** option.
 2. Select the guide object in the window or in the Design Tree.
- To select a guide object in the model window move cursor next to it. When the symbolic notation of the object appears click the left mouse button.

Building a vertex construction line perpendicularly to a straight object passing through the previous vertex of the curve is not possible since the construction direction cannot be identified positively.

2.5.4.8.6. Creating Vertex Associations with Point Objects. Peculiar Features of Associated Vertices

The vertex of a spline or a polyline may contain an associative relation with a point object. Due to the available relation, the vertex will follow any moves of the object. An associative relation is built if the **Associate** option is on during the point object selection. The current vertex row in the Vertices Parameters Table will show a symbol denoting the vertex relation to the point object (see Fig. 2.5.27 on p. 377).

You can use reference points when creating a polyline or spline vertex by any method: **By Points**, **By Axes** and **By Objects**.

- ▼ When constructing “By Points” the vertex directly coincides with the specified point object.
- ▼ When constructing by axes or by objects the vertex coincides with the projection of the specified point object onto its construction line.

In both cases the relation with the point object is maintained until manually deleted. A change in the method of constructing a vertex does not invalidate the relation.

For example, suppose, a vertex related with a reference point was constructed “by points” - i.e. directly coinciding with the reference point. During subsequent editing the user chose to apply “by axes” method of construction to the vertex and specified axis X as the guide. Since the re-

lation with the point object was not deleted, the curve will be reconstructed in such a way that the edited vertex coincides with the projection of the specified point object onto axis X .

Vice versa, if the vertex coincided with the projection of the point object onto the vertex construction line prior to editing, then, as a result of changing the construction method to “by objects”, it will coincide with the point object itself.

If the curve vertex was created with the **Associate** option off, the curve vertex will coincide with the selected point object (or its projection), but will not be related to it - i.e. while moving the point object the vertex position will remain unchanged.

2.5.4.8.7. Closed or open curve

3D splines and polylines may be open or closed. To select a construction variant, activate the **Open Curve** or **Closed Curve** switch in the **Closure** group. When the curve is closed, a segment connecting the starting and the ending vertices is added to it; in case of opening, the segment is deleted.

2.5.4.8.8. Editing Vertex Parameters

You can change the parameters of any already created vertex of a spline or a polyline without leaving the curve construction command.

To edit the existing vertex, select it in the model window or activate the corresponding row in the table of vertices of the curve.

Control elements of the Property Bar allow you to change the method, by which a selected vertex was created: **By Points**, **By Axes** and **By Objects**.

Selecting construction type “by axes” enables changing the axis parallel to which the curve vertex construction line is built.

Selecting construction method “by objects” enables modification or creation of the object used as the guide.

The parameters of a vertex not related to the point object can be changed as follows.

- ▼ In the cells of the vertices parameters table:
 - ▼ set the values of the vertex coordinates;
 - ▼ For a spline: vertex weight;
 - ▼ for a polyline: vertex rounding radius.
- ▼ Modify vertex position in the Model window by the cursor.
- ▼ Change the values of the vertex coordinates or the distance separating the vertex being edited from the previous one using the fields on the Properties bar.

If the vertex is related to a point object its parameters can be edited as follows.

- ▼ Delete the vertex relation to a point object and then use the methods as described above.
- ▼ Modify the point object position.
- ▼ Specify a different point object.

If the vertex was constructed using the **By Points** method with a point object specified, changing the construction method will affect its position.

The table may not be used to associate a vertex with a point object. An associative relation is built if the **Associate** option is on during the point object selection in the Model window. The symbol denoting the relation of the vertex with the point object appears in the row of the current vertex. The relation can be only deleted in the table.

Be careful when deleting a relation, since this action cannot be undone. To restore the relation you should edit the vertex by recreating or specifying the required point.

To switch from editing the spline or polyline vertices and continue to enter vertices, select the **Continue Vertex Input** command from the drop-down menu or activate the last (unnumbered) row in vertices parameters table.

2.5.4.9. 3D Spline

To create a 3D-spline, apply the **Spline** command.

To create a spline, you need to sequentially define vertices of its base polyline (below— “spline vertices”).

The spline vertex can be constructed as follows:

- ▼ **By Points** (see Section 2.5.4.8.3 on p. 379).
- ▼ **By Axes** (see Section 2.5.4.8.4 on p. 381).
- ▼ **By Objects** (see Section 2.5.4.8.5 on p. 383).

Select the vertex construction methods from the **Construction Method** drop-down list on the Properties bar.

The first vertex of a spline can be constructed only using the **By Points** method.

The typical examples of defining a vertex coordinates are:

- ▼ Entering coordinate values into the vertices parameters table (see Section 2.5.4.8.1 on p. 376);
- ▼ creating a special point (see Section 2.5.2.11 on p. 346),
- ▼ Linking a vertex to a point object (see Section *Linking the vertex to a point object* on p. 380).

The **Type** group of switches enables selection of the spline type: spline by vertices or spline by poles (see Section 2.5.4.9.1 on p. 387).

If the original/final spline vertex belongs to a model existing object, you can mate the spline with such object. The **Matings** tab on the Properties bar is used to specify mating conditions (see Section 2.5.4.9.2 on p. 388).

The **Associate** option enables building an associative relation between the spline vertices and point objects (see Section 2.5.4.8.6 on p. 384).

If necessary, you can change the shape of spline by points by controlling tangency and curvature at any of its vertices. To do this, highlight a line in the table of parameters with the number of the required vertex and click the **Control of the form in points** button on the special control bar. The system will enter the spline form control for the current vertex mode (see Section 2.5.4.9.4 on p. 391).

If the initial and the ending vertex of the spline is mated with the model object, you cannot control the spline form for these vertices. Delete the preset mating to be able to control the spline form in this vertex (for example, using the context menu commands **Delete control parameters— In the point** or **Delete control parameters— In all points**).

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the spline, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361). This tab also shows the name of the spline coordinate system name (object coordinate system is detailed in Section 2.8.3.4.1 on p. 598).

The spline with the current parameters is displayed on the screen as a ghost. The ghost dynamically updates on changing parameters.

Upon completion of the point parameterization click the **Create Object** button on the Advanced Control Panel.

The created 3D spline will appear in the model window whereas its icon will be displayed in the Design Tree. Subordinate objects of the spline in the Design Tree are its vertices.

2.5.4.9.1. Spline Type

To select a spline type, enable a desired switch in the **Type** group: **Spline by Vertices** or **Spline by Poles** (Table 2.5.8).

Tab. 2.5.8. Spline types

Curve Type	Construction result
 Spline By Vertices	Spline runs through all vertices with coordinates specified in the table.
 Spline by poles	The spline goes through the extreme vertices tangent to outermost segments of the reference polyline and does not go through intermediate vertices (they are called the spine's "poles"). Distance from the spline to the pole depends on the Weight parameter of this pole.

When building a spline by poles, the **Order** and the **Weight** fields become available.

By default, the spline has order 4, while all poles have the weight of 1. The order may be in the range from 2 through 10 whereas the weight — in the range from 0.0001 through 999.

- ▼ To set the spline's order, enter the right value in the **Order** field.
- ▼ In order to set the weight of the spline's pole, select the pole and enter the required values in the **Weight** field. The pole's weight can also be specified in the **Weight** column of the table of the vertices' parameters (see Fig. 2.5.27 on p. 377, a).

For details on curve order and point weight refer to Section 2.5.1.4 on p. 329.

2.5.4.9.2. Mating Spline with Model Objects

The spline may be mated to an object existing in the model (**mating object**) at the initial or the final vertex (**mating vertex**). In order to perform a mating operation the mating vertex must belong to the mating object.

The following may be used as mating objects:

- ▼ single-segment 3D curves (or separate segments of the multi-segment curves),
- ▼ auxiliary and coordinate surfaces,
- ▼ sketch lines,
- ▼ edges,
- ▼ faces of surfaces and bodies

The user may select one of the four mating conditions: **Not Specified**, **By Tangent**, **Smooth** and **Perpendicularly** (see Section 2.5.1.7 on p. 332).

The mating conditions are specified during creation or editing the spline on the **Matings** tab of the Properties bar.

Fig. 2.5.30. **Matings** Tab

Availability of each mating condition for the initial or the final vertex depends on the mating type.

- ▼ If the mating subject is represented by a surface or a face, the following mating conditions are available: **Not Specified** and **Perpendicularly**.
If the mating vertex lies on the curve being part of a surface or a face (e.g. on an edge), the curve can be used as the boundary object in relation to which the mating condition is specified. In this case all the mating conditions will be available.
- ▼ If the mating subject is represented by a 3D line being a straight object (i.e. polyline segment), the following mating conditions are available: **Not Specified**, **By Tangent**, and **Smooth**. Mating with other types of 3D curves can be performed under all the mating conditions (types of 3D curves are listed in Table 2.1.7 on p. 131).

The mating direction can be changed using the **Direction** group of switches. The group becomes unavailable on selecting a spline mating condition — **Not specified**.

Mating

To mate a spline to a mating subject:

1. Select the initial or the final vertex of the spline to specify mating parameters. To do this, activate the desired switch in the **Initial/Final Vertex** group. The selected vertex will be highlighted in the model window.
2. Select the mating subject in the model window. The selected object will be highlighted whereas its name will appear in the **Mating Subject** field.
3. If necessary, specify the boundary object in the model window. The selected object will be highlighted whereas its name will appear in the **Boundary** field.
4. Select a mating condition from the **Condition** list. The conditions which may not be applied to the vertex selected are not available.

The ghost of the spline being created in the model window will be reconstructed according to the mating condition selected and the mating condition symbol will appear next to the vertex.

Spline mating **By poles** with other objects have some peculiarities, see Section 2.5.4.9.3 on p. 389.

Deleting a Mating

The user may delete the spline mating at the initial or the final vertex or at all the vertices simultaneously.

To delete the specified mating at the current — i.e. initial or final — vertex use the **Delete Control Parameters— At Point** drop-down menu command. To delete the specified matings at all the vertices use the **Delete Control Parameters— At All Points** drop-down menu command.

The specified mating may be deleted at the initial or the final vertex by means of the **Reselect** command. To do so activate the necessary switch in the **Initial/Final Vertex** group of switches on the Properties Bar, then click the **Reselect** button on the Advanced Control panel.

Please be advised that you may not restore the mating once deleted. You may only redo the mating in order to restore it.

If the spline vertex is assigned the system pole attribute, the spline mating may be deleted by removing the attribute. To do so highlight the system pole row in the vertices parameters table and click on the system pole icon in the **Relation** column or use the **Delete Relation** command from the table drop-down menu. The relation will be deleted. The vertex coordinates will remain unchanged.

2.5.4.9.3. Peculiarities of the spline's mating **By poles** with Other Objects. System pole

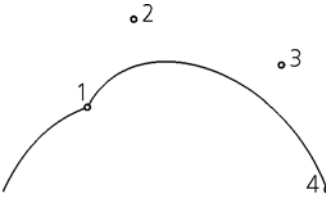

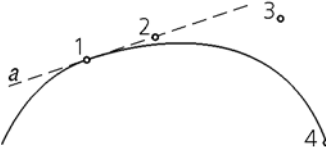

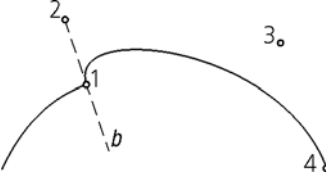

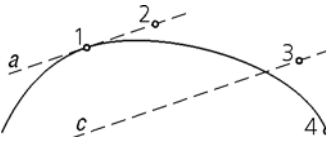

Using **Perpendicular**, **By tangent** and **Flat** mating conditions for a spline **By poles** has the following peculiarities.

The mating is formed by applying certain geometrical limitations in the position of the spline's poles adjacent to the mating vertex. These constraints are automatically applied to poles after the mating condition selection. If you need, a pole is offset by the minimum required distance. The spline's poles with automatically applied limitations become **system poles**. In the Vertices

Coordinates table system poles are marked with a special sign, see Fig. 2.5.27 on p. 377.

Limitations applied to system poles and the number of the system poles required for meeting different conditions of the mating are listed in Table 2.5.9.

Tab. 2.5.9. Number of system poles required for mating conditions, and geometrical constraints for these poles

Mating condition	Number of system poles; geometrical constraints for them	Example*
Not specified	0; no constraints	
By Tangent	1; constraint: relation of the straight line <i>a</i> , tangent to the mating object in the mating point	
Perpendicular	1; constraint: relation of the straight line <i>b</i> , perpendicular to the mating object in the mating point	
Smooth	2; constraint for the first pole: relation of the straight line <i>a</i> ; constraint for the second pole: relation of the straight line <i>c</i> parallel to <i>a</i> at a distance depending on the mating object's curvature in the mating point and on the distance between this point and the first pole.	

* In Figures as numbers are marked: 1 – the vertex of the spline's mating with the object, starting vertex; 2 and 3 – poles of the spline; 4 – ending vertex of the spline.

Spline's mating in the initial (ending) point is possible, if it has the number of adjacent poles sufficient for the mating; these poles should not be system ones (i.e. they should not be used for mating in the opposite vertex).

For **Flat** mating, the order of the spline should be 4 or higher.

If the poles adjacent to the mating vertex are associated with point object or constructed by means of the **By Axes** or **By Objects** method, upon the mating condition selection the message regarding changing the construction method and re-positioning of vertices will appear on the screen.

Click **OK** to confirm modification of the vertex parameters: i.e. change of the construction method to **By Points**, cancellation of the associative relation with the point object and, if necessary, change of coordinates. The edited vertex acquires the status of a system pole — this will be indicated by the system pole symbol in the vertices parameters table in the corresponding row of the vertex (see Fig. 2.5.27 on p. 377).

To cancel modification of the vertex parameters, click the **Cancel** button in the message. In this case the mating condition remains unchanged — i.e. **Not Specified**.

2.5.4.9.4. Handling the Spline Shape

If the spline is built by points, you can change its form managing tangency and/or curvature in the current vertex.

Changing the spline's form is possible in the spline's form management mode for the current vertex. To enter this mode, select the required vertex in the model window, or the line with this vertex's number in the parameter table, and then click the **Spline form management in vertices** button on the Special control bar.

If the initial and the ending vertex of the spline is mated with the model object, you cannot control the spline form for these vertices. To control the spline form in the starting or ending vertex, delete the preset mating in this point (for example, using commands of the contextual menu **Delete control parameters— In the point** or **Delete control parameters— In all points**).

After entering the management mode, the **Parameters** tab contains the table of the vertices' parameters and the **Control** list with options of the spline form control for the current vertex (Fig. 2.5.31). In the list, select the desired control option.

Fig. 2.5.31. **Control List**

The control options are described in more detail below.

Set parameters of the selected option using control elements of the Property bar or using the control ghost in the model window.

The ghost of the spline to be created in the model window will be re-built, a symbol of the control option appears near the current vertex.

In the spline form control mode, you can change the position of the current vertex by moving it with the mouse to the model window or by setting the required values of the vertex's coordinates in the parameter table (see Section *Changing of the vertex parameters in the table of parameters* on p. 378).

After finishing editing the spline's form at one of vertices, you can:

- ▼ set the spline's form for its another vertex; to do this, highlight the required vertex in the model window or a line with this vertex number in the vertices' parameter table,
- ▼ leave the spline's form control mode; to do this, click the **Form control in points** button on the Special control bar,
- ▼ finish construction of the spline — to do this, click the **Create Object** button.

Tangency control

Use this option to control the spline's form for the current vertex by setting the tangent's direction and the value of tangency.

Value of tangency indicates how close is the spline's form to the tangent circle near its current vertex (see Section 2.5.1.6 on p. 331 for more information about the tangent circle).

Curvature of the spline in the current vertex is defined by the system automatically using the preset tangency value.

To use this option, choose the **Tangency** option in the **Control** list of the Property bar.

Using the property bar's control elements or hot points of the controlling ghost, set the tangent's direction for the current vertex and the tangency value for this vertex. For more information on setting parameters listed above see Section 2.5.4.9.5 on p. 393.

Curvature control

Curvature control is control of the spline form on a given vertex by setting curvature or the radius of curvature.

- ▼ Setup of curvature includes determining of normal vector direction and specifying of curvature value.
- ▼ Setup of curvature radius includes determining of curvature center location and specifying of curvature radius value.

The spline's tangency at the current vertex is defined by preset curvature value and curvature radius value.

To use this option, choose the **Curvature** option in the **Control** list of the Property bar.

Using control elements on the Properties toolbar or handles of the managing ghost, specify direction, curvature or curvature radius in the current vertex. For more information on setting parameters listed above see Section 2.5.4.9.6 on p. 394.

Tangency and curvature control

Use this option to change the spline's form at the current vertex using two parameters—tangency value and curvature.

To use this option, choose the **Tangency and curvature** option in the **Control** list of the Property bar.

Select a method of control using switches of the **Method** group:

-  ▼ Enable the **Tangent orientation and tangency value control** switch to set the direction of tangent and tangency value at the current vertex (see Section 2.5.4.9.5 on p. 393).
-  ▼ Enable the **Normal and curvature orientation control** to change the spline's form managing the curvature or curvature radius (see Section 2.5.4.9.6 on p. 394).

Aside from enabling the **Method** group of switches, you can click the mouse at hot points of the “Tangency” ghost “Tangency” and “Curvature” to change between the methods.

2.5.4.9.5. Setting orientation of the tangent and the tangency's value

You can set the orientation of the tangent and tangency value using the controls of the Properties bar (Fig. 2.5.32) or using the handles of the managing ghost (Fig. 2.5.33).

Fig. 2.5.32. Property bar when controlling the tangent's orientation and tangency's value

Fig. 2.5.33. Controlling ghost when controlling tangent's orientation and tangency

Direction of the tangent vector in the current vertex

You can set the direction of the tangent vector in the current vertex using the guide object or the rotation of the managing ghost.

Setting of the guide object for the tangent vector is detailed in Section 2.5.4.9.7 on p. 396, rotation of the managing ghost— in Section 2.5.4.9.8 on p. 396.

If required, you can reverse the obtained direction of the tangent vector. To do this, click the **Change Direction** switch.

Tangency

To set up the spline's tangency value at the current vertex, enter the required value into the **Tangency** field and press the <Enter> key. The spline ghost is being reconstructed.

You can also set up tangency value using the handle of the “Tangency” controlling ghost (see Fig. 2.5.33 on p. 393).

2.5.4.9.6. Setup of the Curvature and the Orientation of the Normal

You can set the curvature or the radius of curvature using the controls of the Properties bar (Fig. 2.5.34) or using the handles of the managing ghost (Fig. 2.5.35 and 2.5.37).

Setup of Curvature

1/R

To set up the curvature in the current vertex, activate the **Curvature** switch in the **Parameter** group. Curvature controls will become available on the Property bar (see Fig. 2.5.34).

Fig. 2.5.34. Property bar when controlling normal orientation and curvature
The managing ghost will be displayed (Fig. 2.5.35).

Fig. 2.5.35. Managing ghost when specifying the curvature

Setup of curvature includes determining of normal vector direction and specifying of curvature value.

Direction of the normal vector in the current vertex

To determine the normal vector direction, use the following methods:

- ▼ setting of the guide object;
- ▼ rotation of the managing ghost,

For more information on setting the normal vector direction see Section 2.5.4.9.7 on p. 396, on rotation of the managing ghost— see Section 2.5.4.9.8 on p. 396.

If required, you can reverse the direction of the normal vector. To do this, click the **Change Direction** switch.

Curvature

To set up the curvature value, enter the desired value into the **Curvature** field and press the <Enter> key. The spline ghost is being reconstructed.

You can set up value of curvature using the handle of the “Curvature” managing ghost (see Fig. 2.5.35).

R

Specifying the curvature radius

To set up the curvature radius in the current vertex, activate the **Curvature Radius** switch in the **Parameter** group.

Control elements for joining curves will appear on the Properties Bar (Fig. 2.5.36).

Fig. 2.5.36. Property bar when controlling the center's position and curvature radius value
The managing ghost will be displayed (Fig. 2.5.37).

Fig. 2.5.37. Managing ghost when specifying the curvature radius

Setup of curvature radius includes determining of curvature center location and specifying of curvature radius value.

Radius of curvature may be specified using one of the following methods:

▼ Manual specifying of the center of curvature

Enter the desired coordinates of the center of curvature into the corresponding fields of the Properties bar. The controlling ghost assumes the desired position. The distance from the current vertex to the center of curvature is displayed in the **Radius** field. If needed, you can change the obtained value of the radius of curvature. To do this, enter the desired value into the field and press the <Enter> key.

The controlling ghost will be re-built – the center of the curvature will move at the desired distance along the radius. Coordinates of the center of curvature are recalculated.

In addition, position of the center of curvature can be set with mouse in the model window. To do this, move the handle of the managing ghost to the required position. Note that the tangent circle and normal vector rotate around the tangent vector.

▼ Use of Guide Object

This method includes the following actions:

- ▼ specifying a guide object for the radius of curvature in the current vertex,
- ▼ specifying of the radius of curvature value at that vertex.

Any point, straight or planar object can be used as a guide object (see Table 2.1.7 on p. 131).

The direction defined by a point object is a line passing through this point object and the current vertex, by a straight object—a line, parallel to the object, by a flat object—a line, perpendicular to the object. Specify the guiding object in the Design Tree or Model Window.

Moreover, the guide object may be represented by a vector. To create a vector, click the **Vector drawing** button on the Advanced Control Panel (see Section 2.8.5 on p. 613).

The name of the selected or created object is displayed in the **Guide Object**. The controlling ghost assumes the preset position, the curvature center is positioned on the radius, the radius will have its current value.

Specify the radius of curvature value. To do this, enter the desired value into the **Radius** field and press the <Enter> key. The spline ghost is being reconstructed.

Note that if a point objects is used as a leading object, the curvature center will coincide with this object. The distance from the current vertex to the center of curvature is displayed in the **Radius** field, the fields for entering the coordinates of the center of curvature are not available.

You can also set up value of the radius of curvature using the handle of the “Radius” managing ghost (see Fig. 2.5.37).

You can reverse the obtained (by the first or the second method) direction of the radius of curvature. To do this, click the **Change Direction** switch of the Properties bar.

2.5.4.9.7. Guide object for the vector

Any point, straight or planar object can be used as a guide object for the tangent vector or the normal vector (see Table 2.1.7 on p. 131).

The direction defined by a point object is a line passing through this point object and the current vertex, by a straight object—a line, parallel to the object, by a flat object—a line, perpendicular to the object.

In addition, the guiding object may be represented by a vector (see Section 2.8.5 on p. 613). To create a vector, click the **Create Vector** button on the Advanced control panel.

Select the guide object in the Design Tree or in the model window or build a vector.

The name of the selected or created object is displayed in the **Guide Object**. The controlling ghost assumes the desired position, the spline's ghost will be re-built.

If a straight line object is used as a leading object, you can select vector's direction: parallel or perpendicular to the guide object. This is done by the **Orientation** group of switches.

2.5.4.9.8. Rotation of the managing ghost

You can rotate the managing ghost around any of the basis vectors using the controls of the Properties bar (on the basis vectors, see Section 2.5.1.5 on p. 331).

The **Rotation** group of switches of the Properties bar allows to select a vector around which the managing ghost will rotate.

- ▼ Activate the **Around the Tangent Vector** switch so that the ghost rotates around the tangent vector. After that, enter the angle of revolution value into the **Angle** field.

- ▼ Activate the **Around the Normal Vector** switch so that the ghost would rotate around the normal vector. After that, enter the angle of revolution value into the **Angle** field.

- ▼ Activate the **Around the Binormal Vector** switch so that the ghost would rotate around the binormal vector. After that, enter the angle of revolution value into the **Angle** field.

The controlling ghost assumes the desired position, the spline's ghost will be re-built.

You can also rotate the guide ghost around the basis vectors using the handles “Around the Tangent Vector”, “Around the Normal Vector”, “Around the Binormal Vector” or, arbitrarily, us-

ing the “Rotation” handle (see Fig. 2.5.33 on p. 393 and 2.5.35 on p. 394).

- ▼ If a **Tangency** control option is used, the rotation of the controlling ghost is only possible around the normal vector or binormal vector. That is why ghost does not have “Around the Tangent Vector” handle and **Around the Tangent Vector** switch is unavailable in the **Rotation** group.
- ▼ If a **Curvature** control option is used, the rotation of the controlling ghost is only possible around the tangent vector or binormal vector. That is why ghost does not have “Around the Normal Vector” handle and **Around the Normal Vector** switch is unavailable in the **Rotation** group.
- ▼ If a **Tangency and curvature** control option is used, the rotation of the controlling ghost is possible around all basic vectors. Therefore, the ghost contains all handles and all switches in the **Rotation** group are accessible.

Note that if a tangent or a normal relates to the leading object when using the **Tangency and curvature** option, its position in the space will be fixed. In this case, you can set direction of another straight line (normal or tangent):

- ▼ by rotation of the controlling ghost around the desired straight line using its hot point,
- ▼ by specifying the leading object which is perpendicular to the desired straight line.

2.5.4.10. 3D Polyline

To construct a 3D polyline, apply command **Polyline**.

To create a polyline, you need to sequentially define its vertices.

A polyline vertex can be constructed as follows:

- ▼ **By points** (see section 2.5.4.8.3 on p. 379);
- ▼ **By Axes** (see Section 2.5.4.8.4 on p. 381);
- ▼ **By Objects** (see Section 2.5.4.8.5 on p. 383).

Construction method can be selected from drop-down menu **Construction Method**.

The typical examples of defining a vertex coordinates are:

- ▼ Picking a vertex position by the cursor in the Model window,
- ▼ Entering coordinate values into the vertices parameters table (see Section 2.5.4.8.1 on p. 376);
- ▼ creating a special point (see Section 2.5.2.11 on p. 346),
- ▼ Linking a vertex to a point object (see Section *Linking the vertex to a point object* on p. 380).

When picking a vertex position by the mouse in the Model window, take into account the screen plane position in the three-dimensional space of the model window.

The first vertex of a polyline can be constructed only **By points**.

Second vertex is created **By Axes** by default. You can select another mode of construction for this vertex.

When constructing the a new vertex by any method its construction line connecting the vertex with the previous one will appear on the screen. This lets you judge correctness of the input parameters and edit them if necessary.

If necessary, the user may construct several vertices of a polyline between two existing vertices (see Section 2.5.4.10.1 on p. 398). When the construction is finished the new vertices are added to the parameters table. The polyline vertices are re-numbered. To resume construction of new vertices, select the last unnumbered row in the table.

The **Associate** option enables building an associative relation between the polyline vertices and point objects (see Section 2.5.4.8.6 on p. 384).

You can round the polyline's vertices, see Section 2.5.4.10.2 on p. 398.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the polyline, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361). This tab also shows the name of the polyline coordinate system name (object coordinate system is detailed in Section 2.8.3.4.1 on p. 598).

The polyline with the current parameters is displayed on the screen as a ghost. The ghost dynamically updates on changing parameters.

Upon completion of the point parameterization click the **Create Object** button on the Advanced Control Panel.

The created 3D polyline will appear in the model window whereas its icon will show in the Design Tree. Subordinate objects of the polyline in the Design Tree are its vertices.

2.5.4.10.1. Inserting of Range of Vertices

To insert range of vertices between the two current ones you should click the **Insert range of vertices** button. The system initiates creation of new vertices between two existing curve vertices.

Use the cursor to define boundary curve vertices that will limit the set being inserted.

A vertex cannot be selected as a second vertex if it has the number which is less than the number of the first one.

The curve section between boundary vertices will disappear.

Create new vertices of the polyline. The methods of building a range of vertices are identical to those used for constructing a polyline (see Section 2.5.4.10 on p. 397). The parameters of the inserted vertices are displayed in the vertices parameters table.

To complete insertion click the **Create Object** button on the Special Control Panel.

The vertices of the inserted set will replace the vertices that previously were between the boundary ones. The inserted vertices' parameters will be added to the Parameters Table. The polyline vertices will be renumbered.

2.5.4.10.2. Vertex rounding

In order to round a polyline's vertex, highlight the required vertex in the model window and enter the value of the rounding radius in the **Radius** field in the Property Bar. Besides that, you can enter radius in the respective cell of the table of the vertices' parameters (see Fig. 2.5.27, b).

If the polyline is closed, you can round any vertex. If it is open, any vertex can be rounded, except for the starting and ending ones.

You can also control the rounding radius in the model window by moving handles. The **Handles** group of switches in the Property bar allows you to specify, which handles of a polyline should be displayed on the screen:

- ▼ If the **All handles** switch is enabled, two points will be displayed in each vertex (except for the starting and the ending vertices of the open polyline): one for changing the vertex's position; another one for changing the rounding radius.

- ▼ If the **Handles of vertices and non-zero fillets** switch is enabled, the point for changing the fillet radius is displayed only if the value of the radius is not equal to zero. Thus, in the vertices with zero radius (as well as in the starting and ending vertex of the open polyline) one point is displayed; in all other vertices, two points are displayed.

2.5.4.11. Spline by Objects

You can create a spline with the shape identical to the shape of a model object (or objects). You can use 3D curves, edges of bodies and surfaces, contours in sketch as source objects.

- ▼ A single spline shall be created when source objects form a chain and are smoothly connected.
- ▼ Several separate splines shall be created when source objects do not form a chain or are not smoothly connected.

A spline created by source objects does not differ from a spline created by the **Spline** command (see Section 2.5.4.9 on p. 386). That is why you can use standard methods of spline editing for the constructed spline.

To create a 3D spline by source objects, call the **Spline by Objects** command.

Select an object or objects for creation of a spline in the model window. 3D lines may be defined in the Design Tree.

Source objects may be also selected before the command selection.

To cancel object selection, re-select it.

The switches of the **Mode** group allow you to select whether the source objects will be saved after the application of the command or not.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the spline, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361). This tab also shows the name of the spline coordinate system name (object coordinate system is detailed in Section 2.8.3.4.1 on p. 598).

To finalize the construction, click the **Create Object** button on the Special Control Panel.

- ▼ If you select spline construction without deletion of source objects, then the created spline will appear in a model window and the spline's icon will appear in the Design Tree.
- ▼ If you have selected the spline construction mode with deletion of source objects then the object deletion dialog should be displayed. The dialog allows to preview the model objects being deleted. You can cancel or confirm the deletion.

- ▼ If deletion is canceled: the spline appears in the model window, while initial objects remain.
- ▼ If deletion is confirmed: a spline appears in the model window, while initial objects disappear.

Note that no link is formed between the spline and the selected object, i.e. deleting or editing the object does not affect the created spline.

Only objects that belong to it, but not to its components, can be deleted from a model. It is impossible to delete the objects that belong to the assembly components. If you select the objects of components for spline creation, then, after clicking the **Create Object** button, a spline will be created and the screen will show a message that the deletion of selected objects is impossible.

2.5.4.12. Curve by law

Allows to create a curve by specifying it with parametric equations.

For details on curve parametric representation see Section 2.5.1.2 on p. 327.

Curve is an object that uses coordinate system (for object coordinate system, refer to Section 2.8.3.4.1 on p. 598).

Parametric equation of the curve can be set in the rectangular, cylindrical or spherical coordinates. By default, the curve is constructing in the rectangular coordinate system that coincides with the curve coordinate system. Cylindrical or spherical coordinate systems are relative to the coordinate system of a curve in the same way as of a point (see Section 2.5.3.4.1 on p. 358).

To create a curve by parametric equation, complete the following steps.

1. Call the **Curve by Law** command.

The curve ghost will be displayed in the default view.

2. Select a coordinate type to be used for curve construction. To do this, activate the relevant switch in the **Coordinate Type** group on the Properties bar:

- ▼ **Rectangular X,Y,Z**,

- ▼ **Cylindrical R,A,Z**,

- ▼ **Spherical R,A,B**

3. Specify functions for the point coordinates of the curve (see Section 2.5.4.12.1 on p. 401).

All changes are displayed in the curve ghost in the model window.

4. If necessary, change name and color of the created curve, set up its display parameters. For that, use control elements on the **Properties** tab of the Property bar. This tab also displays the name of the curve coordinate system.

For detailed information on display parameters of the curve see Section 2.5.4.1 on p. 361.

5. Click the **Create Object** button on the Special Control Panel.

The created curve appears in the model window, while its icon appears in the Design Tree.

2.5.4.12.1. Setup of function for the point coordinates of the curve

You can set function for each coordinate of the curve's point by a linear, cubic, or parametric equation (see Section 2.5.1.2 on p. 327 for more information about the curve's parametric representation). Moreover, you can set a constant value for a coordinate.

The set of coordinates, for which functions are set, depends on which type of coordinates had been chosen for construction of the curve (see p.2, Section 2.5.4.12 on p. 400). For example, if the curve is being constructed in the cylindrical coordinate system, functions are set for coordinates R, A, Z.

Setting a function for the coordinate includes selection of the function's type, and then setting its parameters.

To select a function type for the coordinate, open the **Function by coordinate name** list on the property bar and specify the required line in it (see Fig. 2.5.38).

Fig. 2.5.38. **Function type by X** list

The Property Bar will display controls for setting up the parameters of the function of the selected type. Setting parameters of the function of each type is described in Table 2.5.10.

Before completion of the command the system “remembers” the data entered for every type of function, so you can switch between function types without loss of their data.

Tab. 2.5.10. Setup of function parameters for the point coordinates of the curve

Type of function	Setup of function parameters for the point coordinates of the curve
Constant	The coordinate is set by a constant value. Enter or set by counter the required value of the coordinate in the Value by the coordinate name field.
Linear	The coordinate's function is set by a linear equation. Enter the start and end coordinate value in the respective fields on the Property bar.
Cubic	The coordinate's function is set by a cubic equation. Enter the start and end coordinate value in the respective fields on the Property bar

Tab. 2.5.10. Setup of function parameters for the point coordinates of the curve

Type of function	Setup of function parameters for the point coordinates of the curve
By expression	<p>The coordinate's function is set by a parametric equation. Enter the functions' equation, which determines the coordinate, in the Expression of the function by the coordinate name field. Then, enter data about the function's parameters in the Interval parameter field: name and interval to change.</p> <p>More information on entering the function's expression is described in Section 2.5.4.12.2. Description of the parameter's function is described in Section 2.5.4.12.3 on p. 405.</p>

You can use constants to set the point's coordinates (see Table 4 Appendices IV). For functions of the **Constant**, **Linear**, **Cubic** type, the designation of the constant in the coordinate field will be replaced by its value after entering the constant and pressing the *<Enter>* key. For functions of the **By expression** type, the value of the entered constant will be used during the calculation of the coordinate by the defined function's expression.

A curve can not be created if for all point coordinates the **Constant** type of function is selected. In this case, a warning appears on the screen that at least one coordinate function should not be a constant.

2.5.4.12.2. Entering an expression and setup of function parameters

To enter the function's expression, which defines a coordinate, use the **Function's expression by the coordinate name** field.

The function's expression may contain an **interval** parameter and **non-interval** parameters (see Section 2.5.4.12.3 on p. 405). For example, in the function's expression for Z coordinate which is shown on Fig. 2.5.39, t parameter is an interval one, while parameters r and h are non-interval ones.

Note that the name of the interval parameter should not be the same as the names of non-interval parameters.

The following methods can be used to enter the expression:

- ▼ Manual entering of expression,
- ▼ insert a variable model into expression;
- ▼ insert expression elements from collection;
- ▼ insert group law from collection—insertion of function's expressions for all coordinates at once.

Examples of expression entering are described below.

If there is no interval parameter function in the expression, the function's value will be the result of this expression's calculation, i.e. the constant. To make creation of a curve possible, a function of at least one coordinate should contain an interval parameter, i.e. it should not be a constant.

An expression can include any number of blank spaces. Those are ignored when interpreting the expression.

After entering an expression, press *<Enter>*.

If there are Russian letters in an expression or operation signs do not match, or there are symbols which do not denote operations/functions, the syntax error warning message will appear on the screen.

After entering the function's expression, non-interval parameters are inserted into the **Parameters' values** table on the property bar.

Table consists of three columns. The first column represents the names of expression parameters, the second— expressions for their calculation, the third— their values (see Fig. 2.5.39). Work with table is similar to work in Variables Window (for details about Variables Window see Section 7.1.1.3 on p. 1571).

Name	Expre...	Value
r	20.0	20.0
h	5.0	5.0

Fig. 2.5.39. Example of the table of function parameter values along Z coordinate

Manual entry

You can enter the function's expression in the **Function's expression by the coordinate's name field** from the keyboard.

When entering expressions, you can use existing user variable model as parameters, including functional models (see Section 7.1.5 on p. 1589). For this, parameter name should match the variable name. The data on variable (for a user variable – name and expression, for a functional variable – name, expression and argument) is imported into a **Values of the Parameters** table of the Variables Window. Changing of this data in table is unavailable.

If the name of parameter does not match with any of the variables names, this parameter is recorded into table with default value. Activate the cell of parameter by double clicking the mouse in the **Expression** column and enter the desired parameter value. Press the *<Enter>* key. Once the curve has been created, the variable with the name of the preset parameter will appear in the list of the model's variables.

The functional variable which is used in the function's expression should be created in the Variables window prior to creation of a curve by law.

After creation of a curve, you can edit variables used in it— enter a new value of variable or an expression to calculate it in the Variables Window. After the model is rebuilt, the shape of curve is changed.

In expression you can use arithmetical operators, constants, functions and formulas (see Tables of Appendix III and Tables 1, 2, 3 and 4 of Appendix IV). Operators, constants, functions, and formulas can be copied into the **Function's expression by the coordinate's name** via the exchange buffer.

A model variable insertion

You can insert existing variable into the function expression by choosing it from the model variables. To do this, click the **Insert Variable Name** button on the Advanced Control panel. The **Variables** dialog containing the list of all model variables appears on the screen. To specify the required variable, select any cell in a row of this variable and then click the **OK** button in the dialog.

A variable name is added to the expression of function, its data transferred into the **Values of the parameters** table (see Fig. 2.5.39).

The **Insert variable name** button is available, if the cursor is in the **Function expression by coordinate name** field.

insert expression elements from collection

In the function's expression, you can insert element's expressions from collection (system functions, curve function expressions, and so on). To do this, click the **Insert Function from collection** button on the Advanced Control panel. The dialog for insertion of a mathematical expression will appear on the screen. Select the required expression element or make expression from several elements and click the **OK** dialog button. For details on working in dialog, see Section 7.1.3.4 on p. 1582.

The **Insert function from collection** button is available, if the cursor is in the **Function expression by coordinate name** field.

Insertion of a group law from collection

You can set a group law from collection for a curve. In this case every coordinate will be determined by its own function.

To set the group law, click the **Group Law** button of the Special Control Panel. The dialog for insertion of a mathematical expression will appear on the screen. Select the desired group law from the list and click the **OK** dialog button. For details on working in dialog, see Section 7.1.3.4 on p. 1582.

Once the group law is inserted, functions for respective coordinates appear in **Function expression by coordinate name** fields.

If the group law sets functions for X and Y coordinates only (for example, the involute of circle law), the expression of function for Z coordinate will not be changed – default value will be kept. If necessary, you can edit this expression.

2.5.4.12.3. Setting interval parameter of the function

By default, the name of the function's interval parameter is t , interval of its change is $[0.0;1.0]$. You can change the name of the function's parameter and the borders of its interval. For this purpose, enter the required data in the **Interval Parameter** field and press $\langle Enter \rangle$.

The entered data will be added to the list and saved for the duration of a KOMPAS-3D working session.

Note that the name of the function's interval parameter should not be the same as the names of non-interval parameters of the function and the names of the model's user variables.

As threshold values of the interval, you can use numeric values or constants (see Table 4 Appendices IV). After entering a constant and pressing $\langle Enter \rangle$, the designation of the constant will be replaced by its value.

If the function's parameter name for the current coordinate is the same as the name of the function's parameter for a previously set coordinate, the change interval of the function's parameter for the current coordinate will be determined automatically– will be the same as previously set interval. In this case, editing the parameter change interval for the current coordinate will not be available.

Coordinates of a curve's point can be set by functions of different parameters. Each parameter can have its own change interval.

In order to set the change interval for the function's parameter, you can use the existing interval variable (see Section 7.1.5.1.2 on p. 1591). Enter its name in brackets after the equal sign in the right part of the **Interval Parameter** field and then press $\langle Enter \rangle$. Value of the interval variable (change interval borders) is assigned to the operation's parameter. In this case, editing the parameter change interval will not be available.

You can also set the change interval for the function's parameter by specifying a new interval variable with the required value. For this purpose, complete the following steps in the **Interval Parameter** field.

1. In brackets, enter the required interval of values (for example, $[10;-10]$).
2. After the equal sign in the right part of the field, enter the name of the new interval variable (in brackets).
3. Press $\langle Enter \rangle$.

Once the curve is created, the name and the value of the new interval variable will appear in the Variables Window, section **Intervals**.

Henceforth, changing the interval variable value in the Variables Window will be transferred to the curve, and the curve will be rebuilt in accordance with the new interval of the function's parameter change.

When creating a curve by law, interval variables will be created. The values of these variables are the defined intervals of functions' parameters change. They are placed in the variables section of the created curve (see Fig. 7.1.9 on p. 1590).

You can assign the value of an existing user interval variable to the interval variables of the operation's parameter. For this purpose, enter the name of the required user variable in the **Expression** field of the operation's parameter variable. The value of the user variable will be assigned to the operation's parameter variable and transferred to the model, i.e. the parameter change interval borders of the function, that defines the point's coordinate, will be changed.

For the curve to change in accordance with the new interval limits, the model should be rebuilt.

Hence, when changing the value of the user variable, the value of the respective operation's parameter variable will be changed automatically.

Working with variables is described in detail in Section 7.1 on p. 1569.

2.5.4.12.4. Creation of curves by parametric equation – Example

Example 1

You need to construct a parabolic curve set by law: $y = x^2$, within range between -10 and 10.

Parametric representation of parabola in the rectangular coordinate system:

$$x = t,$$

$$y = t^2,$$

$$z = 0.$$

We recommend to do the following to create a parabola.

1. Call the **Curve by** command.
By default, the **Rectangular X,Y,Z** switch is enabled in the **Coordinate Type** group. It means that the curve is constructing in the rectangular coordinates.
2. Specify function for the X coordinate.
 - 2.1. Choose the **By expression** function type in the **Function by X** list.
Two fields appear on the Properties bar: the field for entering function's expression and the field for entering the function's parameter name and its change interval. The fields contain default data. name t and default change interval [0;1].
 - 2.2. Enter the parameter change interval in the **Interval parameter** field
 $t = [10;-10]$. Press <Enter>.
3. Specify function for the Y coordinate.
 - 3.1. Choose the **By expression** function type in the **Function by Y** list.
 - 3.2. Enter the function t^2 expression in the *Function expression by Y* field.
The t parameter change interval is defined automatically and is the same as the previously set interval for X coordinate.
 - 3.3. Press <Enter>.
4. Specify function for the Z coordinate.

- 4.1. Choose the **Constant** function type in the **Function by Z** list.
- 4.2. Enter value **0** in the *Value by Z* field.
5. Click the **Create Object** button on the Advanced Control Panel.

Example 2

For a calculation related to a cable or wire dip, a chain line set by law should be constructed: $y = a \cdot \text{ch}(x/a) = a/2 \cdot (e^{x/a} + e^{-x/a})$, within the range between -50 and 50 if $a = 80$.

Parametric representation of curve in the rectangular coordinate system:

$$\begin{aligned} x &= t, \\ y &= a/2 \cdot (\exp^{t/a} + \exp^{-t/a}), \\ z &= 0. \end{aligned}$$

We recommend to do the following to create a chain curve.

1. Call the **Curve by** command.
By default, the **Rectangular X,Y,Z** switch is enabled in the **Coordinate Type** group. It means that the curve is constructing in the rectangular coordinates.
2. Specify function for the X coordinate.
 - 2.1. Choose the **Linear** function type in the **Function by X** list. Fields will appear on the Properties bar for entering the start and end X coordinate value.
 - 2.2. Enter value **-50** in the *Start Value by X* field.
 - 2.3. Enter value **50** in the *End Value by X* field.
3. Specify function for the Y coordinate.
 - 3.1. Choose the **By expression** function type in the **Function by Y** list. Two fields appear on the Properties bar: the field for entering function's expression and the field for entering the function's parameter name and its change interval.
 - 3.2. Enter the function expression in the **Function expression by Y** field.
 $a/2 * (\exp(t/a) + \exp(-t/a))$.
 - 3.3. Press <Enter>. The **Values of the parameters** table will appear on the Property Bar. Parameter a is entered in it.
 - 3.4. Set the value of the non-interval parameter a . To do this, activate the cell of the **Expression** table by the mouse double-click and enter 80 . Press <Enter>.
 - 3.5. Enter the parameter change interval in the **Interval parameter** field
 $t = [-50;50]$. Press <Enter>.
4. Specify function for the Z coordinate.
 - 4.1. Choose the **Constant** function type in the **Function by Z** list.
 - 4.2. Enter value **0** in the *Value by Z* field.
5. Click the **Create Object** button on the Advanced Control Panel.

Example 3

When designing a gear mechanism, you should determine the gear wheel's profile. The wheel's gear is drawn along the evolute of circle.

Wheel's parameters:

- ▼ wheel's module $m = 3$,
- ▼ number of the wheel's teeth $z = 20$,
- ▼ profile's angle $\alpha = 20^\circ$.

Parametric representation of evolvent in the cylindrical coordinate system:

$$R = D_b / \cos(t) / 2 \text{ (radius of the pitch circle),}$$

$$A = \operatorname{tg}(t) - t \text{ (involute angle),}$$

$$Z = 0,$$

where $0 < t < 0,4$ (in radians).

We recommend to do the following to create an involute.

1. Create variables in the Variables Window (see Table 2.5.11).

Tab. 2.5.11. Variables for involute construction

Name	Expression	Comment
m	3	wheel's module
z	20	number of teeth
a	20	profile's angle
D	$m * z$	diameter of the pitch circle
Db	$\operatorname{cosd}(a) * D$	diameter of the main circle

2. Call the **Curve by** command.

3. Select a coordinate type of the curve. To do this, activate the **Cylindrical Coordinates (R, A, Z)** switch in the **Coordinate Type** group on the Properties bar.

4. Specify function for the R coordinate.

- 4.1. Choose the **By expression** function type in the **Function by R** list. Two fields appear on the Properties bar: the field for entering function's expression and the field for entering the function's parameter name and its change interval.
- 4.2. Enter the function $\mathbf{Db / \cos(t) / 2}$ expression in the *Function expression by R* field.
- 4.3. Press <Enter>. The **Values of the parameters** table will appear on the Property Bar. Expression and Db variable value are transferred to the table from the Variables Window.
- 4.4. Enter the parameter change interval in the **Interval parameter** field $t = [0;0.4]$. Press <Enter>.

5. Specify function for the A coordinate.

- 5.1. Choose the **By expression** function type in the **Function by A** list.
- 5.2. Enter the function $\mathbf{\tan(t)-t}$ expression in the *Function expression by A* field. The t parameter change interval is defined automatically and is the same as the previously set interval for R coordinate.
- 5.3. Press <Enter>.

6. Specify function for the Z coordinate.
 - 6.1. Choose the **Constant** function type in the **Function by Z** list.
 - 6.2. Enter value **0** in the *Value by Z* field.
7. Click the **Create Object** button on the Advanced Control Panel.

Entering variables in the Variables windows is generally not obligatory. In this example, it is done to simplify expression for R coordinate.

2.5.4.13. Curve Rounding

You can round an angle formed by two curves. Depending on the relative position of the curves, the fillet is made by a circular arc of specific radius or by a spline lying on a cylindrical surface of specific radius. 3D lines, edges of bodies and surfaces, and sketch lines may be used as source curves.

It is impossible to round parallel segments, as well as concentric arcs.

To round two curves, apply the **Round Curves** command.

The elements for managing curve rounding will appear on the Properties Bar (Fig. 2.5.40).

Fig. 2.5.40. Property Bar for rounding two curves

Specify the source curves in the model window. The names of selected objects will be displayed in the **Curve 1** and **Curve 2** fields.

Source curves should be specified in points located close to the assumed mating point.

After selection of source curves, a ghost of rounding i. e. a circular arc with characteristic point or a cylinder with a characteristic point and a spline will appear on the screen.

The rounding curve is constructed in such a way that its points of tangency with source curves are close to the selection points. Radius of curve rounding is defined automatically and its value is displayed in the **Radius** field. You may define the required fillet radius in the following ways:

- ▼ to enter the radius value in the **Radius** field or to specify it by the counter;
- ▼ to drag the defining point with the mouse.

Radius changing shall be displayed on the fillet ghost in the model window.

By default, trimming of source curves is enabled. In this case a copy is created for the source curve. The curve copy is trimmed in the point of its tangency with the fillet curve. You may disable the trim. Only a fillet curve shall be created in this case.

If the curve trimming option offered by the system differs from the expected one, disable trimming and use the **Curve trimming** command to delete parts of the curves (see Section 2.5.4.16 on p. 414).

The switches of the **Arc** group serve to select a desired direction of rounding.

If edges of one face is selected as the source curves, then you can place their fillet on the same face. To do this, enable the **By Surface** option.

Rounding of other curves on the surface can only be placed on it if the curves are **direct derivatives** with respect to the object containing the surface (see Section 2.1.2.7.2 on p. 114 for more information about viewing objects).

To change source curves, click **Select Other** button on the Special Control Panel and re-select objects.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the fillet, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361).

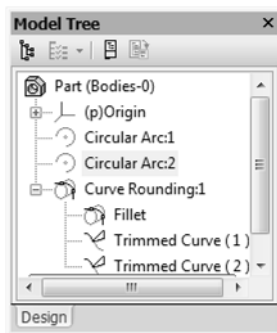

To finalize the construction, click the **Create Object** button on the Special Control Panel.

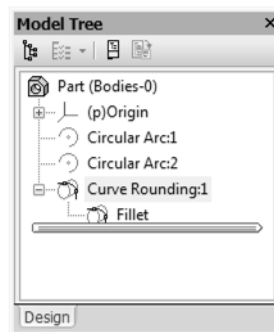

The mating curve appears in the model window and the curve's icon appears in the Design Tree.

- ▼ If source curves were rounded with trimming, then the Design Tree's branch corresponding to this curve rounding will contain subordinated objects: rounding curve and trimmed curves (Fig. 2.5.41, a).
- ▼ If the source curves were rounded without trimming, then the branch of the Design Tree corresponding to this curve rounding will have only one slave object: the rounding curve (Fig. 2.5.41, b).

a)

b)

Fig. 2.5.41. Display of rounding of a pair of curves in the Design Tree:
a) rounding with trimming; b) rounding without trimming

If no fillet ghost is displayed after specifying the source curves then it means that the selected curves can not be filleted close to the specified points. You should change the fillet radius. If the fillet ghost does not appear on the screen after changing the radius, then you should re-define source curves in other points.

2.5.4.14. Joining Curves

You can join vertices of two curves or start and end vertices of a single curve by a joining curve. The following may be used as source curves:

- ▼ 3D lines;
- ▼ edges of bodies and surfaces;
- ▼ contours in a sketch.

You can specify the following mating conditions in the point of joining of a source curve and a joining curve: **Not Specified**, **By Tangent**, **Perpendicularly** and **Smooth** (see Section 2.5.1.7 on p. 332).

You can change the form of a joining curve by means of tension parameter.

To join two curves, call the **Join Curves** command.

Control elements for joining curves will appear on the Properties Bar (Fig. 2.5.42).

Fig. 2.5.42. Property Bar for joining two curves

Specify the source curves in the model window.

A initial source should be specified in a point that is close to the vertex where the joining to the other curve is assumed to be made.

If a 3D line is used as a source curve then it may be specified in the Design Tree. In this case the start point of the curve shall be automatically selected as the joining point.

Source curves may be also selected before the command selection.

To connect the ends of a single curve, you should specify it twice in the model window: near the start vertex and near the end vertex.

By default, the Object Auto Create option is enabled (see Section 1.4.2.10 on p. 93). In this case, the vertices of a curve (or curves) are joined immediately after they selected. Joining will be made with default settings:

- ▼ condition of mating a source curve and a joining curve in both joining points: by tangent;
- ▼ joining curve tension value is 50%.

The joining curve appears in the Model window and the curve icon will appear in the Design Tree. Mate condition icons to appear near the joining curve vertices.

You may control parameters of the joining curve during its creation. To do this, after calling the **Join Curves** command, disable the object auto creation mode (release the **Object Auto Create** button on the Special Control Panel). Then specify the source curves. A ghost of the joining curve with default parameters will appear on the screen.

Select the necessary mating condition for the joining and source curves. To do this expand the **Condition 1** (or **Condition 2**) list on the Properties panel and specify the necessary row.

Set the necessary shape of the joining curve (see Section 2.5.4.14.1 on p. 412).

If needed, you can change the mating vertex of the source curve (see Section 2.5.4.14.2 on p. 412).

All changes are displayed in a ghost of the joining curve in the model window.

To change source curves, click **Select Other** button on the Special Control Panel and re-select objects.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the joining curve, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361).

To finish the construction of the joining curve click the **Create Object** button on the Special Control Panel.

2.5.4.14.1. Specifying Tension for Joining Curve

You can change the form of a joining curve by means of tension parameter. The value of this setting is defined in percentage from 0 to 100.

- ▼ The less the tension setting, the less the curvature of the joining curve in the joining point: the curve is more shallow near the joining points.
- ▼ The more the tension setting, the more the curvature of the joining curve in the joining point: the curve is more shallow in its middle part.

Enter the desired tension value in the **Tension%** field on the Property Bar or specify it by a counter.

2.5.4.14.2. Changing Mating Vertex of Source Curve

If needed, you can change the mating vertex of a source curve. To do this, use the **Start/End Vertex 1** group of switches (or the **Start/End Vertex 2** group of switches). Enable a desired switch in the group corresponding to a source curve.

2.5.4.15. Curve by two projections

You can create curve based on two sketches situated in non-parallel flats. Sketch lines are considered as orthogonal projections of the curve to be created on the sketches' plane. Therefore, the curve is created as a two surface intersection curve; the surfaces are formed by moving specified projections in directions perpendicular to their planes (see Fig. 2.5.43

Fig. 2.5.43. Construction of a curve by two projections

To construct the curve by its two projections, call the **Curve by Two Projections** command. Select the first projection in the model window—a sketch or separate lines in it.

Specify the sketch in the Design Tree or Model Window. In the latter case it is necessary to preliminarily enable the sketch filter using the **Filter Sketches** context menu command (for more information on filtering by object, see Section 2.1.4.1.3 on p. 133). Note that filter is active during the curve by two projections creation only.

First projection lines can be selected also before you call the command.

The name of the object or the number of objects are shown in the **Projection 1** field on the Property Bar.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

Select the second projection—a sketch or separate lines in it. The name of the object or the number of objects are shown in the **Projection 2** field.

The curve ghost will be displayed.

The absence of ghost is an indication that no curve can exist with the selected source objects.

To cancel object selection, re-select it.

All the changes will be reflected in the curve ghost.

The created curve may consist of one or several contours. Select the contours required for construction (see Section 2.5.4.15.1 on p. 414).

To change the projection objects click the **Select Other** button on the Advanced Control panel and re-select the objects.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the curve, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361).

To finish the construction of the curve by two projections, click the **Create Object** button in the Special Control Panel.

The created curve by two projections will appear in the model window, and intersection icon appears in the Design Tree.

2.5.4.15.1. Selection of contours for curve creation

The created curve may consist of one or several contours.

The **All Contours** option on the Property Bar enables selection of the necessary contours for construction. By default, the option is enabled. This means that all the resulting contours will be constructed.

If you need to keep only some of the contours disable the **All Contours** option. The **Contours List** panel containing a list of contours will appear on the Properties bar. Available options are displayed to the left from the contour names. By default all the options are enabled. Selecting a corner from the list will highlight it in the Model window. Disable the options of the contours which are not to be created.

To use or exclude most of the contours operate buttons **Enable All** and **Disable All** above the list.

2.5.4.16. Curve Trimming

You may construct a trimmed copy of a curve.

Open curve, 3D curve, contour in a sketch, edge of a surface or a body 3D curve (or its segment), sketch line, edge.

The following may be used as the secant object:

- ▼ any point object lying on the curve being trimmed (origin point, point in space, vertices of lines in sketches, separate points in sketches, vertices of 3D lines, vertices of edges etc.);
- ▼ object intersecting the source curve:
 - ▼ coordinate or auxiliary plane;
 - ▼ coordinate or auxiliary axis;
 - ▼ 3D line;
 - ▼ edge;
 - ▼ face;
 - ▼ a sketch line.

The source curve and the secant object should have a common point not coinciding with any vertex of the source curve.

To create a trimmed curve, call the **Trim Curve** command.

The elements for managing curve trimming will appear on the Properties Bar (Fig. 2.5.44).

Fig. 2.5.44. Property Bar for curve trimming

Specify the source curve in the model window. You can select a 3D curve in the Design Tree.

A source curve may be also selected before the command selection.

Specify the secant object in the model window or in the Design Tree.

After selection of the source curve and the secant object a copy of the source curve shall be created that is split in two parts by the intersecting point. The part of the copy that does not contain the selection point of the source curve shall be displayed as a ghost on the screen. The ghost shall show the result of the source curve trimming. It is limited by two points: the intersection point and the end point of the source curve (Fig. 2.5.45).

Fig. 2.5.45. A ghost of trimmed curve

Tangential point of the copy of source curve and the secant object is considered to be the intersecting point.

The **Change Direction** switch allows to select another part of the curve for the deletion, i. e. the opposite one in relation to the intersecting point.

You may also change the direction of trimming by specifying the other end point of the source curve in the model window.

If the source curve and the secant object have several common points then a ghost of the trimmed curve and the intersection point of selected objects shall be displayed. In this case the ghost of the trimmed curve is limited by the first intersection point **1** and the end point of source curve **2**. You may select other points **1** and **2** that limit the ghost.

- ▼ To specify a new position of point **1**, specify the required intersection point in the model window (Fig. 2.5.46).

- ▼ To set a new position of point **2**, specify the required intersection point holding the **<Ctrl>** key

Fig. 2.5.46. Changing of point **1** position:
a) selection of intersection point; b) result

pressed (Fig. 2.5.47).

Fig. 2.5.47. Changing of point **2** position:
a) selection of intersection point; b) result

To change the source curve and the secant object, click **Select Other** button on the Special Control Panel and re-select objects.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the trimmed curve, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361).

To finish the construction of the trimmed curve click the **Create Object** button on the Special Control Panel.

The trimmed copy of the source curve will appear in the Model window and the icon of trimming will appear in the Design Tree.

A 3D curve is automatically hidden after trimming.

You can trim a source curve by two secant objects (see Section 2.5.4.16.1 on p. 416).

2.5.4.16.1. Curve Trimming by Two Objects

You can create a copy of the curve trimmed by two objects. To do this, enable the **Two Intersecting Objects** option. The **Secant Object 2** switch will appear on the Property Bar, the **Change Direction** switch will disappear (Fig. 2.5.48).

Fig. 2.5.48. Property Bar for curve trimming by two objects

Select the source curve and the secant objects in the model window or the Design Tree. A trimmed curve ghost limited by points of intersection of the source curve and the secant objects **1** and **2** will appear on the screen (Fig. 2.5.49).

Fig. 2.5.49. Trimmed curve ghost limited by points of intersection of source curve with secant objects

If the second secant object intersects the source curve in several points, then only the first intersection point will be displayed on the screen, other ones will be hidden (Fig. 2.5.50,a). To display them, press the <Ctrl> key. In this case all points of intersection with the first secant object will disappear, except for the point limiting the ghost (Fig. 2.5.50, b).

Fig. 2.5.50. Ghost of curve trimmed by two objects:
a) without pressing the <Ctrl> button; b) with pressing the <Ctrl> button

You can change the position of points **1** and **2** by specifying the desired intersection points.

Note that the ghost of a trimmed curve is always limited by points of different secant objects.

2.5.4.17. Equidistant Line

You may build a curve which is equidistant to the base one.

The following objects may be used as a base curve:

- ▼ a 3D curve,
- ▼ an edge,

- ▼ a sketch line,
- ▼ Chain of objects listed above in any combination.

To create an equidistant curve run the **Equidistant Line**.
Select the base curve in the model window.

A base curve may be also selected before the command selection.

A ghost of the equidistant curve with default parameters will appear on the screen. The base curve start vertex is marked with an arrow.

- ▼ When you select the curve for the second, it becomes deselected.
- ▼ The second selection of a curve from the set makes deselected this curve together with all other curves towards the end vertex.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

The name or number of selected objects is displayed in a field beside the **Curve** switch.

An equidistant curve can be constructed in two ways:

- ▼ **Offset Away from Vertex** (see Section 2.5.4.17.1);
- ▼ **Offset Along Surface** (see Section 2.5.4.17.2).

Select the equidistant line construction method from the **Construction Method** drop-down list on the Properties bar.

Then specify the objects and parameters for constructing an equidistant curve.

All changes are displayed in the curve ghost in the model window.

To change the objects used for constructing the equidistant curve by the selected method click the **Select Other** button on the Advanced Control panel and re-select objects.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the curve, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361).

To finalize the construction, click the **Create Object** button on the Special Control Panel.

The equidistant curve appears in the Model window and the curve icon appears in the Design Tree.

At zero offset the equidistant surface copies the base surface.
Such copy remains integral even if a set of curves has been selected as a base curve.

2.5.4.17.1. Offset Away from Vertex

This method enables setting the position of the equidistant curve by setting off its initial (final) vertex relative to the corresponding vertex of the base curve. The offset operation is performed in the offset plane following the offset vector.

Fig. 2.5.51. Equidistant curve creation by **Offset from the Vertex method**;

Offset plane— is a plane perpendicular to the base plane in its start or end vertex.

The direction of a **offset vector** is specified by means of guide objects.

Guide Objects can be represented by the following objects in the model.

▼ Point objects:

The direction defined by a point object is projection of a line, passing through this point object and the start/end vertex of the base curve, on the offset plane.

▼ Straight Objects.

The direction defined by a straight object is an object projection on the offset plane.

▼ Flat objects.

The direction defined by a plane object is projection of a straight line on the offset object.

Point, straight and flat objects are listed in Table 2.1.7 on p. 131.

In addition, the guiding object may be represented by a vector (see Section 2.8.5 on p. 613).

To create an equidistant line, complete the following steps.

1. Specify the base curve (see Section 2.5.4.17).

Then, the guide object is defined automatically — one of the coordinate axes of the current coordinate system. The name of the axis will display in the field next to the **Direction** switch on the Properties bar.

If necessary, you can select some other guiding object. To do so, activate the **Direction** switch and select the desired guide object in the Design Tree or in the Model window, or build a vector.

The name of the selected object will be displayed in the field next to the **Direction** switch. If the direction is set by means of a vector, the field will contain the word “Vector”.

The set direction is considered default — i.e. initial.

The equidistant line's ghost appears in the model. Its vertex will be at the default distance from the base curve in the initial direction.

2. Set parameters of the offset using any method.

▼ **Manual setting**

In the **Angle** field of the Property bar, enter the rotation angle's value for the offset vector in the offset plane. The angle is calculated from the initial direction.

In the **Distance** field, enter the distance between the base curve and the one being created in the offset plane.

The angle value can be set using a characteristic point (see Section 2.1.4.2.2).

▼ By specifying a point

Click the **Object** button in the Property bar. Then, specify the point object.

The values defining position of the starting (ending) point of the equidistant line are displayed in the **Angle** and **Distance** field. The angle is calculated from the initial direction.

- ▼ If the **Associate** option is enabled, specifying the point object results in forming of the associative link between the starting (ending) point of the equidistant line with that object.

The presence of relation is manifested by displaying a checkmark on the **Object** button and the name of the point object in the **Object** field on the Property Bar. The **Angle** and **Distance** field will not be available for editing in this case.

Thanks to the associative link, the newly created equidistant line will be changing its form while the point is being moved in space.

To cancel the associative link to the point object, click the **Object** button. The tick on the button will disappear.

- ▼ If this option is disabled, the equidistant line without the link to object will be created when specifying the point object. There will be no checkmark on the **Object** button, the object name will not be displayed, and **Angle** and **Distance** field will not be available for editing.

To restore the associative link between the equidistant line and a point object, enable the **Associate** option, click the **Object** button, and reselect the required object.

3. Set the remaining parameters.

- ▼ The **Corner passing** group of switches makes it possible to choose the method of joining the equidistant curve's segments (see Fig. 2.5.52).

Fig. 2.5.52. Corner Treatment Methods:
a) passing with fillet; b) passing with cut

- ▼ The **Retain radii** button controls creation of the equidistant line by segments of the base curve, mated with circles' curves (for example, radii in a polyline vertices).

If the button is disabled, the equidistant line will be built in these segments with radii that will differ from the radii of the base curve. Their values are calculated automatically (Fig. 2.5.53, a). If the button is enabled, the equidistant line's radii will be the same as the radii of the respective arc segments of the base curve (Fig. 2.5.53, b).

Fig. 2.5.53. Rounding segments of an equidistant curve: a) without saving radii; b) with saving radii

- ▼ The **Initial/Final Vertex** group of switches enables changing the base curve vertex through which the offset plane passes.

2.5.4.17.2. Constructing by Offset Along Curve

This method enables setting the position of the equidistant curve by its offset along the theoretical surface of the specified face to the specified distance from the base curve (theoretical surface is detailed in Section 2.5.1.3 on p. 328). The base curve must belong to the specified face.

It is recommended to specify the curve being the initial or derived object of the specified surface as the base curve.

Example on the use of source object: a curve constructed equidistantly to the curve used for constructing a surface using a curve grid (see Section 2.6.1.8 on p. 458) or a ruled surface (see Section 2.6.1.9 on p. 461).

Example on the use of derivative object: a curve constructed equidistantly to the surface intersection curve.

The distance between the equidistant curve and the base one is measured in the direct line and not along the theoretical surface of the face (Fig. 2.5.54).

Fig. 2.5.54. Equidistant curve constructed using the **Offset Along Surface** method

Specify the face for constructing an equidistant curve.

The specified face is highlighted in the Model window and its name is displayed in the field adjacent to the **Surface** switch.

Set the distance from the base curve to the one being created by entering it into the **Distance** field.

The distance value can be set using a handle (see Section 2.1.4.2.2).

2.5.4.18. Isoparametric Curve

Allows to construct isoparametric curve of a theoretical surface of the specified face going through the selected point of this face.

For more information on theoretical face surface and isoparametric curves see Section 2.5.1.3 on p. 328.

Point position on a face can be specified using two methods:

- ▼ by specifying parameters U and V of the point of the theoretical face surface,
- ▼ by specifying a point object on the specified face within its boundaries; as a point object, you can use:
 - ▼ object's vertex (or a point in space) provided that the object (or point) is **the direct source or direct derivative** with respect to the object, containing the face¹.
 - ▼ face edge vertex.

To create an isoparametric curve, complete the following steps.

1. Call the **Isoparametric Curve** command.
2. Select the desired face in the Model window.

Base face for constructing an isoparametric curve can be also selected before calling the command.

1. It means that in the hierarchy of relationships between the object containing the vertex (or point) and the object containing the face, no more objects should be present (see Section 2.1.2.7.2 on p. 114 for more information about viewing objects' relationships).

The selected face is highlighted. The following will appear on the selected face: ghost of the face indication point and ghosts of isoparametric curves U and V going through this point. The **Surface** field of the Property Bar displays the name of the selected face. The input fields **U Parameter, %** and **V Parameter, %** display values of the U and V parameters at the face indication point. The value counting direction is shown by arrows from the start point U=0, V=0.

- Specify the position of the point through which the isoparametric curve must pass. This can be completed by the following methods:

Method 1

Enter the required values of the U and V parameters in percent (from 0 to 100) in the **U Parameter, %** and **V Parameter, %** fields or use the counter to specify them. All updates shall be displayed on the LCS ghost in the model window. The location of the point also can be changed by moving its handle with the mouse (see Section 2.1.4.2.2).

Method 2

Select the required point object in the Design Tree or in the model window.

The **Object** button will be ticked, and the field next to the button will display the object name. This indicates the associative relation of the point, through which a straight line should pass, with the selected object. Due to this relation, the created curve will follow the object in case it changes its position. If necessary, the relation can be disabled by clicking the **Object** button. The tick on the button will disappear, and the field will be cleared.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

- Select one of two curves for creation.

By default, isoparametric curve of direction U is created— its ghost is active. In this case, the **Curve of Direction U** switch is active in the **Select by Direction** group of switches of the Properties bar.

To create an isoparametric curve of direction V, activate the **Curve of Direction V** switch. The ghost of curve of direction V becomes active.

- If required, you can also:

- Cancel all objects set for construction of a curve. To do this, click the **Reselect** button on the Advanced Control panel.

- Change name and color of the created curve. Enable the **Properties** tab of the Property Bar. Display parameters of the curve can also be set in the same tab (display parameters are detailed in Section 2.5.4.1 on p. 361).

- Click the **Create Object** button on the Special Control Panel.

The isoparametric curve appears in the model window, while its icon appears in the Design Tree. After creating the first curve, the system waits until the user specifies the objects for the next curve.

2.5.4.19. Group of isoparametric curves on the surface

You can create a group of isoparametric curves on the theoretical surface of the selected face. Number of curves of each direction (U and V) in a group are defined by the user and may be different.

For more information on theoretical face surface and isoparametric curves see Section 2.5.1.3 on p. 328.

To create a group of isoparametric curves, call the **Group of Isoparametric Curves** on the Surface command.

Select the desired face in the Model window.

Base face for constructing isoparametric curves can be also selected before calling the command.

The selected face is highlighted. Ghosts of isoparametric curves of U and V directions appear on it. Arrows show the directions of U and V parameters effect in the start point $U=0, V=0$; The **Surface** field of the Property Bar displays the name of the selected face.

Enter the desired number of curves of each direction into the **Number, U** and **Number, V** fields of the Properties bar.

The number of curves of surface parameter direction U (V) is entered in the **Number, U** (**Number, V**) field. It is the curves of direction V(U) positioned with equal spacing by parameter U(V).

The **Boundaries** group of switches controls construction of boundary curves corresponding to the boundaries of theoretical surface. **Save Boundaries** option button is active in this group by default. It means, the group of curves will be created with edged curves.

If you need to create a group without edged curves, activate the **Delete Boundaries** switch.

The **Explode** option controls the result of curve group construction.

- ▼ If option is disabled, after completion of the command curves will be displayed in the Design Tree as objects subordinated to the group.
- ▼ If the option is enabled, after completion of the command, curves will not be subordinated to the group, and each curve will be displayed in the Design Tree as a standalone object.

To change the face used for constructing a group of curves click the **Select Other** button on the Advanced Control panel and re-select the face.

You can change the name, color and display parameters of curves of group in the **Properties** tab of the Properties bar (display parameters are detailed in Section 2.5.4.1 on p. 361).

To finish the construction of the group of isoparametric curves, click the **Create Object** button in the Special Control Panel.

The isoparametric curves appear in the model window, the group of isoparametric curves or the set of separate isoparametric curves in the Design Tree (if the **Explode** option was enabled).

To expand the list of curves of the group, click the mouse on the “plus” sign located at the left of the group icon in the Design Tree.

At first, the Design Tree contains V-direction isoparametric curves splitting the face in U direction and then U-direction isoparametric curves splitting the face in V direction.

Please note that option **Explode** is available on the Property bar only when creating the group. If you need to transform already created group into a set of individual curves, you may explode the group. Group breakup is performed similarly to breaking up an array (see Section 2.7.1.3.7 on p. 517). After group breakup, every curve is displayed in the Design Tree as an individual object – isoparametric curve.

2.5.4.20. Outline Line

You can build the **face outline line** which is the line in whose points the face's normal is perpendicular to the specified sight direction.

Face edges are not included into the outline line.

You cannot build the online line of a face, if the face is flat or the face's normal in each its point is perpendicular to the direction of sight.

Outline line can be created for a set of faces (see Fig. 2.5.55).

Fig. 2.5.55. Outline Line: a) of one face; b) of set of faces

To create a face outline line perform the following operations.

1. Call the **Outline Line** command
2. After calling the command, the **Surface** switch is enabled on the Property bar automatically. Select the required face(s) in the Model window.

If you need to create an outline line for all faces of a body or a surface, select this body or surface in the Design Tree.

Source objects may be also selected before the command selection.

The selected objects are highlighted. The name of the selected object or the number of selected objects are shown in the **Surface** field on the Property Bar.

The second selection of a face cancels it's selection.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

The outline line ghost will be displayed. By default, an outline line is constructed in the view direction perpendicular to the screen plane.

3. If you need to fix the outline line in the form corresponding to the model current position, enable the **Fix Position** option. With the option disabled the outline line will be reconstructed each time after changing the model orientation.

4. Select the guide object or create a vector in order to specify the view direction (see Section 2.5.4.20.1 on p. 426).

After specifying view direction, the ghost of the outline line changes.

5. An outline line may consist of one or several segments— contours. Select the contours required for outline line construction (see Section 2.5.4.15.1 on p. 414).

6. If required, you can also:

- ▼ Cancel all objects set for construction of a curve. To do this, click the **Reselect** button on the Advanced Control panel.

- ▼ Change name and color of the created curve. Enable the **Properties** tab of the Property Bar. Display parameters of the curve can also be set in the same tab (display parameters are detailed in Section 2.5.4.1 on p. 361).

7. Click the **Create Object** button on the Special Control Panel.

The created outline line will appear in the model window, and its icon will appear in the Design Tree.

2.5.4.20.1. Setup of view direction when creating an outline line.

By default, an outline line is constructed in the view direction perpendicular to the screen plane. You can specify view direction using a guide object or a vector.

Any straight or flat object may function as a guide object. Straight and flat objects are listed in Table 2.1.7 on p. 131.

Direction, defined by a straight object — a line parallel to the object.

Direction, defined by a plane object — a line perpendicular to the object.

Activate the **View Direction** switch and then select an object defining the view direction in the Design Tree or in the model window.

Reselecting of the object cancels its selection and the view direction becomes default— perpendicular to the screen plane.

To create a view vector, click the **Vector drawing** on the Advanced Control Panel (see Section 2.8.5 on p. 613).

The selected object's name will be displayed in the **Projection Direction** field. If the direction is set by means of a vector, the field will contain the word "Vector".

2.5.4.21. Spline on Surface

You can create a spline on the theoretical surface of the selected face. If necessary, face theoretical surface is extended.

For more information on theoretical face surface, see Section 2.5.1.3 on p. 328.

The spline vertex can be constructed as follows:

- ▼ by specifying parameters U and V;
- ▼ by specifying a point object on the specified face within its boundaries; as a point object, you can use:
 - ▼ object's vertex (or a point in space) provided that the object (or point) is **the direct source** or **direct derivative** with respect to the object, containing the face¹.
 - ▼ face edge vertex.

To construct a spline on surface, perform the following steps.

1. Call the **Spline on Surface** command.
2. Specify a face on which it will be located in the model window.

Base face for constructing a spline can be also selected before calling the command.

The selected face is highlighted. Name of the selected object shall appear in the **Surface** field on Properties toolbar.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

3. Set spline vertices. This can be completed by the following methods.

Method 1

Specify the vertex position on the face by a mouse click or enter the required values of the U and V parameters in percent (from 0 to 100) in the **U Parameter, %** and **V Parameter, %** fields.

Method 2

Select the required point object in the Design Tree or in the model window.

The **Object** button will be ticked, and the field next to the button will display the object name. This indicates the associative relation of the spline vertex with the selected object. Due to this relation, the created curve will follow the object in case it changes its position. If necessary, the relation can be disabled by clicking the **Object** button. The tick on the button will disappear, and the field will be cleared.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

Each vertex of the spline is characterized by a set of parameters displayed in the Table of vertex parameters. You can edit the parameters of existing vertices and create new vertices using table controls and table context menu commands (see Section 2.5.4.21.1 on p. 428).

The spline with the current parameters is displayed on the screen as a ghost.

4. Select an option of curve construction— closed or open. To do this, activate the desired switch in the **Mode** group: **Open Curve** or **Closed Curve**.

5. Select the spline type. To do this, activate the desired switch in the **Type** group: **Spline by Vertices** or **Spline by Poles** (for details about spline types, see Section 2.5.4.9.1 on p. 387).

6. If required, you can also:

1. It means that in the hierarchy of relationships between the object containing the vertex (or point) and the object containing the face, no more objects should be present (see Section 2.1.2.7.2 on p. 114 for more information about viewing objects' relationships).

- ▼ Change of position for the preset vertices and control of the spline by vertices shape. To do this, select a row with the number of desired vertice in the parameters table. The system is switching to a spline editing mode (for more about spline editing see Section 2.5.4.21.2 on p. 429). You can delete spline vertices in this mode. To activate the spline construction mode, select the last (unnumbered) row of the table. In addition, you can switch between the construction and editing spline modes by using the **Finish/Continue Vertex Input** context menu command.

- ▼ Change of face for constructing a curve To do this, click the **Reselect** button of the Special Control Panel and select other face and spline vertices.

- ▼ Change name and color of the created curve. Enable the **Properties** tab of the Property Bar. Display parameters of the curve can also be set in the same tab (display parameters are detailed in Section 2.5.4.1 on p. 361).

7. Click the **Create Object** button on the Special Control Panel.

The created spline will appear in the model window whereas its icon will be displayed in the Design Tree.

2.5.4.21.1. Table of Spline Vertex Parameters

Every spline vertex is characterized by a set of parameters. Their values are displayed in the Table of Vertices.

This table is called **Vertices Coordinates (U,V)** and is located on the Properties Bar.

Each spline vertex corresponds to a table row.

The table contains the following parameters:

- ▼ Vertex number,
- ▼ the values of vertex parameters (U,V),
- ▼ Relation mark is the spline vertex is associated with a point object,
- ▼ weight (while constructing the spline by poles);
- ▼ relation and system pole marks (while constructing the spline by poles).

System pole of a spline on surface is similar to a system pole of a spline mated **By Tangent** with a model object. For more information on the system pole, see Section 2.5.4.9.3 on p. 389.

N		U	V	Weight
1	<input type="checkbox"/>	36.0	23.0	1.0
2	<input checked="" type="checkbox"/>	100.0	0.0	1.0
3	<input checked="" type="checkbox"/>	75.0	20.0	1.0
4	<input checked="" type="checkbox"/>	81.8514	100.0	1.0
	<input type="checkbox"/>			

Apex coordinates (UV) << Management

Fig. 2.5.56. Sample Spline Vertex Parameter Table

The table rows are formed automatically during vertex construction in the model window. At the same time, creating or editing the table row shall involve creation of a new table or will change the parameters for the current curve vertex. In addition, selection of row of existing vertex enables spline edit mode (for more about editing see Section 2.5.4.21.2 on p. 429). Selection of the last (unnumbered) row of the table enables spline creation mode.

Table controls and table context menu commands allow the following manipulations:

- ▼ replacing the entries in all cells of the selected column with the zero value or the first cell value;
- ▼ modify parameter values of existing vertices in the table,
- ▼ Create new vertices,
- ▼ Delete the curve's vertices,
- ▼ Allows deleting the connection of a spline vertex to a point object,
- ▼ cancel conditions of spline's tangency with the curve on the spline's surface (see Section 2.5.4.21.4 on p. 431 for more information on condition of the spline's tangency with the curve).

Creating of new spline vertex is detailed below, other methods of work are described in Section 2.5.4.8.2 on p. 377.

Creating a new vertex

To add new vertex, select a table row with the number of vertex in relation to which adding of vertex will be made, and click the button above the table. The description of buttons enabling to add a new vertex is given in Table 2.5.12.

Tab. 2.5.12. Buttons for spline vertices adding

The	Description
 Insert a vertex before the current	Allows to add a vertex between the current and previous. Upon clicking the button, new vertex appears and new row containing new vertex parameters is added to a table. New vertex gets the number of current vertex, numbers of following are increased by one. You may also add a new vertex by pressing the <i><Insert></i> key.
 Duplicate vertex	Allows to add a new vertex which coordinates and weight have to be the same as current vertex has (weight for spline by poles). Upon clicking the button, new vertex appears and new row containing this vertex parameters is added to a table. New vertex gets the number of current vertex, numbers of following are increased by one.
 Insert vertex after current one	Allows to add a new vertex between the current and next. Upon clicking the button, new vertex appears and new row containing new vertex parameters is added to a table. New vertex gets the number that follows in order the number of current vertex, numbers of following vertices are increased by one.

2.5.4.21.2. Spline edit mode

In editing mode you can:

- ▼ change the spline vertex position;

- ▼ control the form of the spline at its vertex – change direction and length of the tangent vector of the spline.

To switch to spline edit mode, select the row with desired vertex number in the table of vertices parameters.

The system automatically switches to the editing mode on running the edit command for an earlier created spline.

The **Control** group of switches on the Property bar allows to select the method of spline editing for the current vertex:

- ▼ **Vertex Position**—a change in vertex position (see Section 2.5.4.21.3 on p. 430);

- ▼ **Tangent vector on a vertex**—control of the spline's tangent vector on the current vertex (see Section 2.5.4.21.4 on p. 431).

In case of a spline By poles, you can control the tangency vector on extreme vertices only. Please note the following specifics of switching to a spline by poles edit mode. Highlighting the line of the initial or ending vertex allows to switch to editing the position of this vertex and to controlling its tangent vector— there is the **Control** group on the property bar. Selecting lines for other vertices makes it possible to switch to editing their positions— there are fields for entering U and V parameters on the property bar.

In addition, you can delete vertices in the edit mode. For this purpose, select the required vertex in the model window and press the *<Delete>* key.

All changes are displayed in the spline ghost in the model window.

After finishing editing spline at the one of vertices, you can:

- ▼ continue setting vertices— highlight the final (unnumbered) line of the table;
- ▼ edit other vertex— to do this, select its row in a table or specify it in a model window.
- ▼ finish the construction of the spline— to do this, click the **Create Object** button.

You can switch between the construction and editing spline modes by using the **Finish/Continue Vertex Input** context menu command.

2.5.4.21.3. Changing of vertex position

To change position of the current vertex of the spline, enable the **Vertex position** switch of the **Control** group on the Property bar.

Control elements for joining curves will appear on the Properties Bar (Fig. 2.5.57).

Fig. 2.5.57. Property bar when changing the position of the current vertex of the spline

There are two ways to change the position of the spline's vertex:

- ▼ specify parameters U and V;
- ▼ bind the vertex with the point object.

Methods of changing the spline's vertices' positions are similar to methods of setting a vertex when creating a spline. These methods are detailed in item 3 of Section 2.5.4.21 on p. 426.

2.5.4.21.4. Controlling the tangent vector of the spline

You can change the direction and length of the spline's tangent vector for the current vertex.

The spline's tangent vector for the current vertex can have arbitrary direction or tangent to the curve going through this vertex.

The following may be used as a curve:

- ▼ curve on selected face or edge of this face;
- ▼ isoparametric curve of a theoretical surface of the specified face.

You can change the length of the tangent vector as you wish.

Spline tangency condition setting

To switch to controlling the spline's tangent vector, enable the **Tangent vector in the vertex** switch in the **Control** group of the Property bar.

Control elements will appear on the property bar to make it possible to set conditions of spline tangency with respect to the current point. Select the required spline tangency condition from the **Tangency** list (Fig. 2.5.58).

Fig. 2.5.58. Property bar when editing the tangent vector in the current vertex of the spline

Tangent vector control is described in Table. 2.5.13.

Tab. 2.5.13. Spline tangent vector control at the current vertex

	Tangency condition	Tangent vector control
	Not specified	After choosing this condition, spline shape at the current vertex takes a default view.
	By direction	Allows to manually edit parameters of the vector. Once the tangency option is selected, the tangency vector appears on the screen as a dashed segment with a handle. You can edit vector length and direction by moving with mouse its handle.

Tab. 2.5.13. Spline tangent vector control at the current vertex

	Tangency condition	Tangent vector control
	To isoparametric curve U;	Use it to set the vector's tangential direction with respect to U (or V) isoparametric curve of the specified surface. Once the above tangency condition is set, the vector will be positioned tangentially with respect to the isoparametric curve. Vector of the selected direction appears on the screen. You can edit vector length by moving with mouse its handle.
	To isoparametric curve V;	
	To a curve on surface	Use it to set the tangential direction of the vector with respect to a curve on the specified surface. After choosing this tangency condition, vector with default direction appears on the screen. Tangency designation will appear near such a vertex. Specify in the model window a curve or an edge which define vector direction. Then change vector length by moving with mouse its handle.

The ghost of the spline being created in the model window will be reconstructed according to the tangency condition selected and the tangency condition symbol will appear next to the vertex.

The **Change Direction** switch makes it possible to reverse the tangent vector direction.

Note that in case of a spline By poles, you can control the tangency vector on extreme vertices only. Once parameters of the tangent vector of the extreme vertex have been changed, the vertex adjacent to it is given the property of a system pole— a symbol of the system pole appears in the table of vertices' parameters in the line of this vertex (see Fig. 2.5.56 on p. 428). If vertices adjacent to the extreme ones are related to point objects, then after selection of the tangency condition, a message will appear on the screen indicating that parameters of these vertices have been changed.

For more information on the system pole, see Section 2.5.4.9.3 on p. 389.

Spline tangency condition deletion

You can delete spline tangency condition at the current vertex or at all the vertices simultaneously.

To delete a preset condition of the spline's tangency to the current vertex, select **Not set** from the **Tangency** list on the property bar or call the command of the contextual menu **Delete control parameters — In the point**.

To delete the specified tangency conditions at all the vertices use the **Delete Control Parameters — At All Points** drop-down menu command.

Please be advised that you may not restore the tangency condition once deleted. You may only redo the tangency condition in order to restore it.

If the spline vertex is assigned the system pole attribute, the tangency condition may be deleted by removing the attribute. To do so, highlight the system pole row in the vertices parameters table and click on the system pole icon in the **Link** column or use the **Delete Relation** com-

mand from the table drop-down menu. The tangency condition will be deleted. The vertex coordinates will remain unchanged.

2.5.4.22. Projection curve

You can create a **projection curve** – a projection of the selected curve on a projected surface.

Fig. 2.5.59. Sketch projection on a body's face

2.5.4.22.1. Objects for construction

For construction of a projection curve, you will need a **projection surface** and a **base curve**.

The following can be used as the projection surface:

- ▼ face of the body or surface,
- ▼ Coordinate or auxiliary plane
- ▼ a set of bodies' faces and/or surfaces,

The following objects may be used as a base curve:

- ▼ a 3D curve (including array instances),
- ▼ body or surface edge,
- ▼ a sketch line,
- ▼ a set of the above-mentioned objects,
- ▼ coordinate or auxiliary axis,
- ▼ curve array,
- ▼ a group of isoparametric curves.

Please, pay attention to the following features of the projection line construction.

- ▼ It is impossible to create an axis projection on a plane.
- ▼ If a base curve projection on a plane degenerates into a point, it will be impossible to build it.
- ▼ Projection of an axis is possible, if this projection is located within the projection surface.

2.5.4.22.2. Construction of a projection curve

To create a projection curve, complete the following steps.

1. Call the **Projection Curve** command.

2. After calling the command, the **Surface** switch is enabled on the Property bar automatically. Select the required face or plane in the Model window. The object selection is detailed in Section 2.1.4.1.1 on p. 130.

The selected object is highlighted. Name of the selected object shall appear in the **Surface** field on Properties toolbar.

3. After specifying projection surface, the system will proceed to the selection of base curve, and the **Curve** switch will be activated automatically. Select the base curve in the model window. The name or number of objects is displayed in a field beside the switch.

Note that the axis, curve array, and the group of isoparametric curves may not be included in the set of objects making up the base curve. Therefore, selection of a new axis, for example, cancels selection of all other objects included in a base curve.

The curve ghost will be displayed.

The absence of ghost is an indication that no projection curve can exist with the selected source objects and current construction parameters.

4. If necessary, change the projection surface (for example, you can create a set of faces) and/or a base curve.

▼ In order to change the surface of projection, enable the **Surface** switch and then specify the required objects. A plane may not be included in the set of objects making up the surface of projecting. Therefore, selection of a new axis cancels selection of all other objects included in the surface of projecting.

If you need to add all faces of a surface or a body to the current face set, select the body or surface in the Design Tree.

▼ In order to change the base curve, enable the **Curve** switch and then specify the required objects.

To cancel object selection, re-select it.

All the changes will be reflected in the curve ghost.

5. Select the type of base curve projection: along the normal to selected surface or in the specified direction (see Section 2.5.4.22.3 on p. 435).

6. By default, projection of the reference curve is built within the contour of the face (trimmed by the faces contour) – **Trim by boundaries** option is enabled on the property bar. If you need to construct whole projection, disable the option. Base curve will be projected on the theoretical surface of the face. If necessary, theoretical surface of the face will be extended.

If a set of faces is used as the surface for projection, the base curve projection will be trimmed by the contour of each face of the set by default.

Please, pay attention to the following features of the projection.

- ▼ Base curve projection on a *surface* is always constructed in full.
- ▼ If an *axis* is specified as the base curve, its projection will always be constructed within the projected surface's contour.

In both cases, the **Trim by boundaries** option will not be available.

For more information on theoretical face surface, see Section 2.5.1.3 on p. 328. The Figure shows options for constructing sketch line (base curve) projection on the face with hole.

Fig. 2.5.60. Result of the sketch line projection on a face with a hole:
 a) the **Trim by borders** option is on;
 b) the **Trim by borders** option is off

7. A projection curve may consist of one or several segments - contours. Select the contours which need to be constructed (see Section 2.5.4.15.1 on p. 414).
8. If required, you can also:

- ▼ Cancel all objects set for construction of a curve. To do this, click the **Reselect** button on the Advanced Control panel.
- ▼ Change name and color of the created curve. Enable the **Properties** tab of the Property Bar. Display parameters of the curve can also be set in the same tab (display parameters are detailed in Section 2.5.4.1 on p. 361).

9. Click the **Create Object** button on the Special Control Panel.
 The projection curve appears in the model window, while its icon appears in the Design Tree.

2.5.4.22.3. Selection of the base curve projection type.

By default, the reference curve is projected by normal to the preset projection plane. In this case, the switch is active in the **Projection Type** group on the Property bar **Normal to Surface**.

You can create base curve projection in the direction specified by an object or a vector. To do this, activate the **By Direction** switch in the **Projection Type** group. The Property bar will display controls for setting up the guide object.

Any straight or flat object may function as a guide object. Straight and flat objects are listed in Table 2.1.7 on p. 131.

Direction, defined by a straight object — a line parallel to the object.

Direction, defined by a plane object — a line perpendicular to the object.

Activate the **Direction** switch and then select an object defining the direction of projection in the Design Tree or in the model window.

Reselecting of the object cancels its selection and the ghost of the curve being created disappears.

To create a vector specifying the direction of projection, click the **Vector drawing** on the Advanced Control Panel (see Section 2.8.5 on p. 613).

The selected object's name will be displayed in the **Projection Direction** field. If the direction is set by means of a vector, the field will contain the word "Vector".

The Figure shows an example of constructing sketch line (base curve) projection on the cylindrical surface.

Fig. 2.5.61. Example of constructing sketch line projection on the cylindrical surface.
 a) projecting of a sketch line along the normal to surface;
 b) projecting of a sketch line perpendicularly to the sketch plane

2.5.4.23. Intersectional Curve of Surfaces

You can build an intersection curve for two surfaces, two sets of surfaces or for a surface and a set.

To build a surface intersection curve, run the **Surface Intersection Curve** command.

Once the command has been called, the **Set of surfaces 1** switch will be enabled automatically in the Property bar. Specify the first intersection object — a face or a surface (object selection is detailed in Section 2.1.4.1.1 on p. 130). The name of the selected object is displayed in the field beside the **Set of surfaces 1** switch.

After the first intersection object is specified, the system switches to the second intersection object and automatically activates the **Set of surfaces 2**. Specify the 2nd or several intersection object(s). The name or number of objects is displayed in a field beside the switch.

If you need to change the first or the second set of surfaces, enable the respective switch and specify the required objects. To cancel object selection, re-select it.

If you need to add all faces of a surface or a body to the current surface set, select the body or surface in the Design Tree.

It is impossible to construct a coordinate plane intersection curve.

The ghost of the intersection curve will display on the screen on selection of intersection objects.

An intersection curve may consist of one or several continuous segments - contours. Select the contours required for construction (see Section 2.5.4.15.1 on p. 414).

To change the intersection objects click the **Select Other** button on the Advanced Control panel and re-select the objects.

The controls contained on the **Properties** tab of the Properties bar enable changing the name and the color of the intersection curve, and set the parameters of its display (display parameters are detailed in Section 2.5.4.1 on p. 361).

To finish the construction of the intersection curve, click the **Create Object** button in the Special Control Panel.

The intersection curve will appear in the Model window and the intersection icon will appear in the Design Tree.

2.5.4.24. Contour

You can create a contour using already existing objects – 3D curves, edges or sketch lines.

To create a contour, call the **Contour** command of the **3D Lines** toolbar. The command is accessible if there is at least one curve, surface, body or sketch in the document.

Select contour type using the **Type** group of switches of the Properties bar or context menu commands.

- ▼ **Automatic Type Detection,**
- ▼ **Arbitrary Contour,**
- ▼ **Contour on edge,**
- ▼ **Sketch Contour.**

The activation of the switch **Automatic Type Detection** means that contour type will be automatically determined by the system after selecting the curves.

Specify objects which comprise the contour of selected type: curves, sketch lines, edges of bodies and surfaces, other previously created contours.

When specifying objects, conditions of continuity of the contour to be created and absence of self-intersections should be met.

For detailed description of contour types and object selection, refer to Section 2.5.4.24.1 on p. 438.

Objects can be selected before calling the command.

The ghost contour will be displayed. Start vertex of the contour is marked with an arrow. Reselecting of the object cancels its selection together with all other objects towards the end vertex of the contour.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

The names of selected objects are displayed in Table **List of Objects** on the Property Bar.

You can create fillets with permanent or variable radius in the contour's angles (see Section 2.5.4.24.2 on p. 439). You can also create a contour by the curve's equidistant (see Section 2.5.4.24.3 on p. 440).

To change objects used for contour construction, click the **Reselect** button on the Special Control Panel and re-select objects.

Controls on the **Properties** tab of the Property bar make it possible to adjust the contour's name, color and display parameters. For detailed information on display parameters of curves, see Section 2.5.4.1 on p. 361.

The **Starting/Ending vertex** group of switches makes it possible to change the starting vertex of the contour.

The **Hide source curves** option controls visibility of source objects of the contour after its creation. If it is enabled, curves by which the contour is built will be hidden automatically after the contour's creation.

To finish construction, click the **Create Object** button on the Special Control Panel.

Created contour will appear in the model window, and its icon will be displayed in the Design Tree.

Note that the contour is associated with objects which had been used for its construction, therefore, the contour form changes when forms of these objects change.

2.5.4.24.1. Selecting contour type

You can set following contour types using the **Type** group of switches of the Properties bar or context menu commands.

Arbitrary Contour— a contour composed of 3D curves, edges, sketch lines, other contours, separate segments of the multi-segment curves.

To create an arbitrary contour, select the curves that shall be included in it. For object selection refer to Section 2.1.4.1 on p. 130.

Contour on edge— a contour consisting of one face edges.

To create a contour on face, select its edge that shall be included in contour. One of the faces, to which the edge belongs, will be highlighted. To select an adjacent face instead of this one, click the adjacent face by the mouse.

Specify all necessary settings for the edge's contour of the selected face.

Sketch contour— a contour consisting of one sketch lines.

Specify the sketch lines in the Model window or the sketch in the Design Tree. If the sketch is selected in a Tree, the contour will comprise all its lines; therefore, they should be connected one by one without self-intersections.

Automatic de of type is the default method of contour creation which does not require special selection of type. When the **Type Auto Determination** switch is active, you can select any curves. After the contour creation, its type is determined by the system automatically. To verify this, enter the editing mode of the contour created with the **Type Auto Determination** switch enabled. Enabled switch indicates the contour type.

While selecting, you can switch between types. Depending on which objects are specified for contour creation, the **Sketch Contour**, **Contour on Face** switch or both of them may be unavailable.

After *sketch contour* or *contour on face* creating, you can add objects that do not belong to this sketch or face. To do this, click the **Arbitrary Contour** switch and select objects.

Contour type is important while executing operations. For example, during extrusion operation, selection of a contour type affects the result of the operation (see Section 2.3.2.3.1 on p. 154).

2.5.4.24.2. Creation of a contour with fillets

In order to create fillets in a contour's corners, enable the **Passing with fillet** switch in the **Angle passing** group of the **Parameters** on the Properties bar. Set the fillet's *permanent* radius value in the **Radius** field.

Fillets with the same radius will be displayed in the contour's ghost in the model window. In the first fillet, there will be a handle for controlling the value of the radius. When moving the point with the mouse, all fillets in the ghost will be changing.

In order to set a *variable* radius, i.e. specific radius value in each vertex of the contour, go to the **Variable radius** tab with the **Passing with fillet** switch enabled.

The tab contains the respective bar with the table of parameters: numbers of points and values of radii in them (Fig. 2.5.62, a). If the points are not specified, the table will be empty.

The contour's ghost in the model window displays handles of all radii, numbered from the contour's beginning (Fig. 2.5.62, b).

a)

b)

Fig. 2.5.62. Example of creating a contour with the variable radius of fillets: a) specifying the value of the radius in the table; b) displaying fillets in the contour's ghost

Use the cursor to specify the points the radius of which should be changed. The selected points are displayed in the **Variable radius** table.

Specify the fillets' radii values in these points using any method – by moving handles using the mouse or by setting values in the table.

In order to change the radius value in the table, click or double-click the required cell. Upon a single click, you can enter values by typing from the keyboard, upon a double click, you will be able to enter values by typing from keyboard or selecting by the stepper button.

Fillets are displayed in the contour's ghost in the model window.

You can delete a point from the table using the **Delete** button located above the list. Deletion of a point from the table means that a fillet with the constant radius will be built in it.

2.5.4.24.3. Creation of a contour by the curve's equidistant

You can create a contour by the equidistant of the specified curve when using the **Contour** command.

In order to set parameters of the equidistant, click **Curve's equidistant** button on the Special Control panel.

The system will start creation of the equidistant curve which is similar to the process enabled by the command **Curve's equidistant** (see Section 2.5.4.17 on p. 417). Select the equidistant creation method, then specify the required parameters (enter the values or specify the objects). All changes are displayed in the curve ghost in the model window.

Curves can be specified before starting the process of the equidistant construction.

Upon completion of the equidistant parameterization click the **Create Object** button on the Special Control Panel.

The system will return to execution of the **Contour** command.

The name of the equidistant curve will be displayed in the **List of objects** table in the Property bar as an object for creation of the contour.

You can create angle passing with fillets both in the equidistant and in the contour. Creation of fillets in contours is more convenient, since arbitrary radii values can be set (see Section 2.5.4.24.2 on p. 439).

One contour by equidistant can be created by calling the **Contour** command once. In order to add other curves to the contour, call the **Contour** command again and specify the objects.

Note that the equidistant constructed during creation of the contour will not be displayed in the Design Tree as a standalone object. It will be saved inside the *Contour* object for which it had been created.

In order to change parameters of the equidistant as part of the contour, enter the contour edit mode and click the **Curve's equidistant** button on the Special Control panel. The system will

start the process of editing the equidistant which is the same as the process of its construction. Change parameters of the current method of equidistant creation or choose another method and re-create the curve. Once the editing is finished, click the **Create Object** button to exit the equidistant editing process.

2.6. Surfaces

2.6.1. Creation of surfaces

The following surfaces can be created in the KOMPAS-3D model file:

- ▼ extrusion surface,
- ▼ revolution surface,
- ▼ lofted surface,
- ▼ Sweep;
- ▼ Patch;
- ▼ Ruled,
- ▼ Surface by curve grid;
- ▼ Surface along a point grid,
- ▼ Surface along point formation,
- ▼ Equidistant,
- ▼ Blend surface.

The user may import the surfaces saved into a SAT, IGES or STEP AP203 file into the surface model.

The following surface operations are available:

- ▼ Trimming;
- ▼ Splitting,
- ▼ Extension;
- ▼ Knitting.

Besides that, you can modify or remove individual faces of surfaces and bodies.

Commands to work with surfaces are located in menu **Operations — Surface**. The respective command buttons are located on the **Surface** toolbar (Fig.2.6.1).

Fig. 2.6.1. **Surfaces** toolbar

All of the above-mentioned options for creating surfaces and working with them are described in this section. Besides that, the following operations with surfaces are possible:

- ▼ Scaling (see Section 2.3.8.7 on p. 204),
- ▼ Position changing (see Section 2.3.8.8 on p. 205),
- ▼ saving a new part in file, see Section 2.11.2.3 on p. 689.

Surfaces can be used, for example, to cut a model's part or as an object, which is the limit for extrusion.

During creation, the surface should be integer, i.e. it should not comprise parts. Otherwise, the execution of operation is impossible.

2.6.1.1. Imported Surface

To import surface or surfaces to a KOMPAS-3D model file the following files may be used.

- ▼ File with *sat*, *igs*, *stp* or *step* extension — free surfaces and surfaces of the bodies contained in this file will be inserted into the current model.
- ▼ The coordinate file with *txt*, *xls*, or *ods* extension (see Chapter VI) – the polyface surface will be built in the current model using the coordinates from the file. Every face of surface has triangle shape.

To perform the import, use the **Imported Surface** command.

After calling the command, a standard Select File dialog appears, where you need to select the desired file.

When reading in the **.igs* file containing no topology, a prompt will be displayed for knitting surfaces. An affirmative answer implies that the imported surfaces will be knitted wherever possible.

Once the import has been finished, icon of the imported surface or several icons of imported surfaces will appear in the Design Tree.

The coordinate system of the imported surface or surfaces will be the current coordinate system – absolute or local (see Section 2.8.3.3 on p. 597 for more details about selection of the current coordinate system).

If the coordinate system of an imported surface is not absolute but local, then you can change the position of the imported surface in the model by changing the position of the local coordinate system relative to the absolute coordinate system.

For detailed description of coordinate systems of objects, refer to Section 2.8.3.4 on p. 597.

If an assembly model is stored in the selected *.sat*, **.igs*, **.stp* or **.step* file, the reading will result in creation of parts with imported surfaces in the current model. At saving of the model the files of these parts shall be saved to disk. Those are placed in the same folder as the model.

2.6.1.2. Extrusion Surface

Extrusion surface is created by sweeping section along the straight-line guide in either or both sides at the specified distance.

A face, sketch, edge or 3D curve (including contour constructed by sketch lines, by face edges or arbitrary¹) may be used as a section of extrusion surface.

1. It means that has **Contour on Face**, **Sketch Contour** and **Arbitrary Contour** type, see Section 2.5.4.24.1 on p. 438.

During extrusion of the face, closed sketch, closed **Sketch Contour** or **Face Contour**, the construction of a closed surface is possible (Fig.2.6.2). If the section is open, then surface closing is impossible.

Fig. 2.6.2. Face extrusion: a) section (cylindrical face), b) closed surface, c) open surface

If section is a flat face, sketch, contour constructed by sketch lines or flat face, and it is extruded at the direction perpendicular to it, sloping to side faces of feature is possible (Fig.2.6.3).

Fig. 2.6.3. Slope of side faces of extrusion surface: a) closed, b) open

A sketch used as the section of extrusion surface should satisfy the requirements listed in Section 2.6.1.2.2.

During edge or 3D curve extrusion (including contour of **Arbitrary** type), close and slope of the surface's faces are impossible. Example of 3D curve extrusion is shown in the Figure2.6.4.

Fig. 2.6.4. Extrusion element with a spiral section

2.6.1.2.1. Construction of Extrusion Surface

1. Call the **Extrusion Surface** command.

The surface creation operation starts. The operation parameters management interface items will appear on the Property bar.

2. Specify the operation parameters:

- ▼ **section** — in the same way as in the extrusion operation, see Section 2.3.2.3.2;
- ▼ **extrusion direction** — in the same way as in the extrusion operation, see Section 2.3.2.4;
- ▼ **extrusion depth** — in the same way as in the extrusion operation, see Section 2.3.2.5;

- ▼ **slope angle** — in the same way as in the extrusion operation, see Section 2.3.2.6.

To set up such parameters as slope angle, extrusion direction and depth, you can use handles (handles are detailed in Section 2.1.4.2.2 on p. 138).

All parameter values are displayed on the screen as a surface ghost.

3. If a face, closed sketch, closed **Contour on face** or **Sketch contour** are used as section, the **Closed surface** option will become available. Enable it, if you need to add faces to a face surface, that correspond to the initial and the final position of the section (see Fig.2.6.2, b).

4. click the **Create button** to fix surface.

Surface shall appear in the model window and the corresponding icon — in the Design Tree.

2.6.1.2.2. Requirements to the Sketch of Extrusion Surface

- ▼ Sketch objects can be a part of one or several contours.
- ▼ If there is only one contour, it can be either open or closed.
- ▼ If there are several contours, then:
 - ▼ all of them must be closed.
 - ▼ one of them must be the outer one and the rest must be nested in it; allowed level of nesting — 1.

If a sketch contains nested contours, the correct construction of a surface is possible only if it is closed, i.e. the **Closed Surface** option is on.

2.6.1.3. Revolution Surface

Revolution feature is created by rotation of section about the axis in either one or both sides at the specified angle.

A face, sketch, edge or 3D curve (including contour constructed by sketch lines, by face edges or arbitrary¹) may be used as a section of revolution surface

During rotation of the face, closed sketch, closed **Sketch Contour** or **Face Contour**, the construction of a closed surface is possible (Fig.2.6.5).

Fig. 2.6.5. Face Rotation: a) section (cylindrical face) and axis, b) closed surface, c) open surface

If the section is open, then surface closing is impossible.

1. It means that has **Contour on Face**, **Sketch Contour** and **Arbitrary Contour** type, see Section 2.5.4.24.1 on p. 438.

During edge or 3D curve rotation (including contour of **Arbitrary** type), closing a surface is also impossible. Example of 3D curve revolution is shown in the Figure 2.6.6.

Fig. 2.6.6. Rotation element with a spiral section

If the section is an open sketch or an open contour built by the sketch or flat face's edges and rotates around the axis within the section's plane, the construction type selection is available—toroid or spheroid (Fig.2.6.7).

Fig. 2.6.7. Spheroid and toroid construction (section—sketch—marked with a thickened line): a) spheroid, b) toroid

A sketch used as the section of revolution surface should satisfy the requirements listed in Section 2.6.1.3.2.

2.6.1.3.1. Construction of Revolution Surface

1. Call the **Revolution Surface** command.
The surface creation operation starts. The operation parameters management interface items will appear on the Property bar.
2. Specify the operation parameters (in the same way as in the revolution operation):
 - ▼ **Section** (see Section 2.3.3.3 on p. 168).
 - ▼ **revolution axis** (see Section 2.3.3.4 on p. 169);
 - ▼ **creation type** (see Section 2.3.3.5 on p. 170);
 - ▼ **revolution direction** (see Section 2.3.3.6 on p. 171);
 - ▼ **revolution angle** (see Section 2.3.3.7 on p. 171).

To set up such parameter as angle of revolution, you can use handles (handles are detailed in Section 2.1.4.2.2 on p. 138).

All parameter values are displayed on the screen as a surface ghost.

3. When using faces, closed sketch, closed **Sketch contour** or **Face contour**, the **Closed surface** option is available. Enable it, if you need to add faces to a face surface, that correspond to the initial and the final position of the section (see Fig.2.6.5, b).
4. Click the **Create button** to fix surface.

Surface shall appear in the model window and the corresponding icon — in the Design Tree.

2.6.1.3.2. Requirements to Sketch of Revolution Surface

- ▼ A sketch may contain one or several contours.
- ▼ If there is only one contour, it can be either open or closed.
- ▼ If there are several contours, all of them must be closed.
- ▼ If there are several contours, one of them must be the outer one and the rest must be nested in it.
- ▼ Only one level of nesting is permitted for contours.

If a sketch contains nested contours, the correct construction of a surface is possible only if it is closed, i.e. the **Closed Surface** option is on.

Besides the section, sketch may also contain the rotation axis. In this case, additional requirements shall be met:

- ▼ the axis should be drawn in a sketch as a line segment with *Centerline* line style or as an *Centerline* object type,
- ▼ all contours must lie on the same side of the revolution axis.
- ▼ no contour should intersect the axis (or its extension),
- ▼ some contour points may be on the axis (or its extension),
 - ▼ for closed contours – any of their points and/or segments,
 - ▼ for open contours – only their outermost points.

2.6.1.4. Swept Surface

Swept surface is created by sweeping section along the path.

If section is closed, the construction of a closed surface is possible (Fig.2.6.8). If the section is open, then surface closing is impossible.

Fig. 2.6.8. Swept surface: a) section and path, b) closed surface, c) open surface

Surface section must be displayed in the sketch; any curve or chain of curves can be used as a path. The requirements to the section sketch and surface path are the same, as for the sketch and the path of the swept feature (see Sections 2.3.4.3.1 on p. 174 and 2.3.4.4.1 on p. 175).

Do the following to create a swept surface in the model.

1. Call the **Swept Surface** command. The command is available if there is at least one sketch in the model.

The surface creation operation starts. The operation parameters management interface items will appear on the Property bar.

2. Specify the operation parameters (in the same way as in the sweep operation):

- ▼ **Section** (see Section 2.3.4.3 on p. 174).
- ▼ **path** (see Section 2.3.4.4 on p. 175);
- ▼ **type of section movement** (see Section 2.3.4.5 on p. 175);

All parameter values are displayed on the screen as a surface ghost.

3. When using closed section, the **Closed Surface** option is available. Enable it, if you need to add flat faces to a face surface, that correspond to the initial and the final position of the section (see Fig.2.6.8, b).

4. Click the **Create button** to fix surface.

Surface shall appear in the model window and the corresponding icon — in the Design Tree.

2.6.1.5. Lofted Surface

Surface by sections is formed by joining several sections of arbitrary form and position. Extreme section can be a point.

If sections are closed, the construction of a closed surface is possible (Fig.2.6.9). If the sections are open, then surface closing is impossible.

Fig. 2.6.9. Surface by Sections: a) sections, b) closed surface, c) open surface

If necessary, you can use a centerline during element creation by sections (Fig.2.6.10).

Fig. 2.6.10. Surface by Sections: a) without centerline, b) with centerline

Surface sections must be displayed in the sketch; any curve or chain of curves can be used as a centerline. The requirements to the section sketches and centerline are the same, as for the sketches and the centerline of the lofted feature (see Sections 2.3.5.3.1 on p. 179 and 2.3.5.4.1 on p. 180).

Do the following to create a surface by sections in the model.

1. Call the **Surface by Sections** command. The command is available if there are at least two sketches in the part.

The surface creation operation starts. The operation parameters management interface items will appear on the Property bar.

2. Specify the operation parameters (in the same way as in the operation by sections):

- ▼ **Section** (see Section 2.3.5.3 on p. 178).
- ▼ **Centerline** (see Section 2.3.5.4 on p. 179);
- ▼ **Creation method** (see Section 2.3.5.5 on p. 180).

All parameter values are displayed on the screen as a surface ghost.

3. When using closed sections, the **Closed Surface** option is available. Enable it, if you need to add flat faces that of the same shape as the initial and final sketched sections to a surface (see Fig.2.6.9, b).

4. Click the **Create button** to fix surface.

Surface shall appear in the model window and the corresponding icon — in the Design Tree.

2.6.1.6. Surface Along a Point Grid

Surface created by the point grid — is a spline surface constructed by points that are conventionally grouped in a grid, i.e. the points are arranged in several rows with the same number of points in each row. Merge points are not allowed.

Direction U is the direction of adding points to create a surface. Direction V — is the direction to add rows. Thus, the points of the grid constitute rows in directions U and V.

Fig. 2.6.11. Surface Along Point Grid

2.6.1.6.1. Creating Surface Along Point Grid

To draw a surface with specified end points, click **Surface by Grid of Points**. Control elements for joining curves will appear on the Properties Bar (Fig.2.6.12).

Fig. 2.6.12. Property toolbar if LCS is created by the basic method

Select the surface type using the **Type** group of switches: **By Points** or **By Poles**. A surface by points passes directly through the grid points. A surface by poles passes at a distance from the grid points as defined by their weight. By default, weight of the points is 1; if required, the weight can be changed through the surface edit mode (see Section 2.6.1.6.3 on p. 452).

Specify the surface points (see Section 2.6.1.6.2),

You can define the thread name and color on the **Properties** tab of the Property bar. The segment is constructed parallel to the selected axis of the polyline's coordinate system (for object's coordinate system, refer to Section 2.8.3.4 on p. 597).

If you want to check surface for self-crossing, enable the **Check self-crossing** option.

When you have specified points and surface parameters, click the **Create Object** button on the Special Control panel.

The **Create object** button is accessible if the even number of point rows is input, starting from two.

The created surface will appear in the model window, and the surface icon — in the Design Tree.

If the **Self-Intersection Check** option was enabled and returned a positive result the surface will be marked in the Design Tree with an exclamation mark in a red circle which indicates errors. For more information about self-intersection of surface refer to Section 2.6.1.6.5.

2.6.1.6.2. Specifying Points for Surface Along Point Grid

To specify surface points, select individual point objects in the Design Tree or model window (the list of point objects can be found in Table 2.1.7 on p. 131), group of points (see Section 2.5.3 on p. 348 for more information about groups of points) or array of points (see Section 2.7 on p. 509 for more information about arrays) in the Model Tree or model window.

Selecting objects with the **Associate** option enabled will build an associative relation between the surface points and the objects.

You can create a point by clicking the **Point Drawing** button on the Special Control Panel (for details see Section 2.5.2.11.1 on p. 347).

Specify and create points in the order of their arrangement in a row.

Number of the next point and total number of grid points are displayed in the corresponding fields of the Property Bar.

Having preset points of the first row, click the **Finish the Row** button. This done, the button disappears from the Property Bar. Number of points in the second and following rows is accepted equal to the number of points in the first row.

If you have specified a group of surface points or an array of parallelogram grid points with more than 1 instance on both axes, the number of rows and points will be determined automatically.

Select or create points for other rows.

The screen will show the ghost of the surface being created, the grid ghost and the arrows of directions U and V.

To cancel selection of one or several final points click the **Cancel Selection button** on the Special Control Panel. To specify another reference point, click the **Select Other** button.

If a different number of rows is set (beginning with two) the **Edit** button will be available on the Advanced Control panel. Enables surface edit mode (see Section 2.6.1.6.3 on p. 452).

If none of the grid points is specified (i.e. immediately after running the command or clicking the **Re-select** button) the following buttons are available on the Advanced Control panel:

- ▼ **Read from File** which enables acquiring point coordinates saved into a file (more information about the data file can be found in Appendix VI); the systems interprets the numbers saved in the file as point coordinates in the Cartesian coordinate system which coincides with the surface coordinate system (for more information about the object coordinate system see Section 2.8.3.4 on p. 597),

- ▼ **Surface Grid** which allows to construct a surface using the grid which approximates any of the existing ones to the surface models (see Section 2.6.1.6.4 on p. 453).

2.6.1.6.3. Surface Editing Mode Along Point Grid

To switch to the editing mode click the **Edit** button on the Advanced Control panel. Property toolbar contains controls shown in Figure 2.6.13.

Fig. 2.6.13. Property bar in Edit Surface by Point Grid mode

The system automatically switches to the surface editing mode on running the edit command for an earlier created surface.

In this dialog you can

- ▼ change position and weight of points, delete and add rows,
- ▼ change surface order,
- ▼ enable and disable surface closing.

These methods are detailed below.

Moreover, the **Type** group of switches which controls the surface type and the **Self-Intersection Check** option which verifies the surface for self-intersections are available in the surface editing mode.

All updates shall be displayed on the LCS ghost in the model window.

To continue designation of the grid points after editing the surface release the **Edit** button. To stop surface creation, click the **Create Object** button.

Editing Points and Rows

Select the edit method using switches of the **Point Selection** group:

- ▼ Enable switch **By one point** to select points one by one. Select a point to edit, click on it in the model window.

- ▼ To set a new point position, specify a new point object or drag the or select other point construction method (for more details refer to paragraph 3, Section 2.5.2.11.2 on p. 347).

- ▼ To change a point weight (for the **By pole** surfaces), set the required value in the **Weight** field.

- ▼ To select the required row of points, enable either **U direction row** or **V direction row** switch. To specify a row to be edited, click any point of the same row.

- ▼ To add a new row in the same direction, enable either **Insert before the selected row** or **Insert after the selected row** in the **Operations** group on the Property bar. A new row will appear in the point grid. Points in this row are created **By Coordinates (XYZ)**.

- ▼ To delete a row, enable switch **Delete the Selected Row** in the **Operation** group.

- ▼ To change a point weight (for the **By pole** surfaces), set the required value in the **Weight** field. Each point in the row will acquire the specified weight.

Surface order in the U and V direction

The surface order is one of the surface parameters which define its shape. For details about the order of the spline curves and surfaces, see Section 2.5.1.4 on p. 329.

Surface order parameters are set in fields **Order, U** and **Order, V**.

Surface Closing

You may close surface either in U or V direction, or in both directions. To do this use switches **Closed in U** and **Closed in V** are provided.

Closing in either direction is possible if there are three or more points in the respective direction.

2.6.1.6.4. Constructing Point Grid Along Existing Surface

A point grid can automatically be created based on the existing surface model. The following can be used as a surface:

- ▼ solid or surface face,
- ▼ auxiliary or coordinate plane;

To do this, click the **Edit Points** button on the Special Control panel, and then “drag” polyline vertices with the mouse.

The selected surface will be approximated by the spline surface on the grid. The surface' ghost and point will appear in the model window.

- ▼ If the selected surface is an auxiliary or coordinate plane, the approximating surface coincides with the square which displays this plane in the model space.
- ▼ If a face has been specified as a surface, the approximating surface will coincide with the face' theoretical surface (see Section 2.5.1.3 on p. 328). Thus, holes of the selected face will be ignored; in some cases the approximating surface borders do not coincide with contours of the selected face: the surface overlaps the edge. For example, if the selected face is a circle, then the approximating surface will be a square positioned next to the circle.

The approximating surface is always the spline surface, and its borders are spline curves even if a plane or flat face with straight edges is selected for approximation.

2.6.1.6.5. Self-Intersecting Surface

Self-intersection of a surface as a mathematical object is not an error. At the same time self-intersection of a part face is a modeling error since such part cannot be manufactured.

Due to the above it is impossible, for example, to define width using the command of the same name (see Section 2.3.6 on p. 184) since this operation will invariably create a body in error. However, a surface segment devoid of self-intersections can be widened by separation from the rest of the surface by means of trimming (see Section 2.6.2.1 on p. 469).

One more example: extrusion to a surface (see Section 2.3.2.5.4 on p. 159) is impossible if the element section is projected onto the surface at the part where it self-intersects. If the section projects onto the surface part devoid of self-intersection the program will proceed with extrusion.

Since in most cases surfaces are built for further use as body faces such commands as **Surface Along Point Grid** and some others contain the option of checking for self-intersection. If checking is enabled, any surface containing self-intersections will be marked in the Design Tree as surface in error. The need to correct such an error, as illustrated above, depends on which part of the surface is intended for further work.

2.6.1.7. Surface Along a Point Formation

Surface constructed with the aid of the point layer is a spline surface or a polyface surface created by points which form a space layer, i.e. they are arranged in such a manner that the height of their circumscribing rectangle is lower with respect to their length and width.

During execution of the **Surface Along Point Formation** the system interprets the formation as a point grid which is used for surface construction. Therefore, when creating a spline surface this command can be used as an equivalent of the **Surface Along Point Grid** (see Section 2.6.1.6 on p. 450) which does not require manual specification of points. If the automatic point grid recognition result is unsatisfactory, use the **Surface Along Point Grid** command.

The **Surface Along Formation** command yields better results if the formation points form a regular grid with rectangular spaces.

Fig. 2.6.14. Point formation and the surface built along it

2.6.1.7.1. Surface Construction Along Point Formation

To construct a surface along a point formation run the **Surface Along Point Formation** command. Control elements for joining curves will appear on the Properties Bar (Fig.2.6.15).

Fig. 2.6.15. The Properties bar during creating a surface along a point formation

Select the surface type using the **Type** group of switches:

▼ **By points.** A spline surface that passes through the grid points.

▼ **By poles.** A spline surface that passes at a certain distance from the points. The distance is defined by the system and cannot be modified.

▼ **Polyface.** A surface that passes through the grid points. Every face of surface has triangle shape.

Specify the surface points (see Section 2.6.1.7.2),

The **Order** field enables setting the surface order. For details about the order of the spline curves and surfaces, see Section 2.5.1.4 on p. 329.

The switches of the **Method** group are used to select the method of grid points recognition. The method of grid recognition determines the surface shape (see Section 2.6.1.7.3).

To force the command to create a surface along a point grid (not a surface along a point formation), enable the **Result - 'Along Point Grid'** option.

If you want to check surface for self-crossing, enable the **Check self-crossing** option.

If the surface is of a polyface type, the **Order** field, options **Result-"By point grid"** and **Check for self-intersections** will not be available.

You can define the thread name and color on the **Properties** tab of the Property bar. the segment is constructed parallel to the selected axis of the polyline's coordinate system (for object's coordinate system, refer to Section 2.8.3.4 on p. 597).

When you have specified points and surface parameters, click the **Create Object** button on the Special Control panel.

The **Create Object** button becomes available if the user specifies three or more points.

▼ Surface Along Point Formation icon;

▼ Surface Along Point Grid icon (if the **Result - 'Along Point Grid'** option was enabled).

If the **Self-Intersection Check** option was enabled and returned a positive result the surface will be marked in the Design Tree with an exclamation mark in a red circle which indicates errors. For more information about self-intersection of surface refer to Section 2.6.1.6.5.

2.6.1.7.2. Specifying points for a surface along a point formation

To specify surface points, select individual point objects in the Design Tree or model window (the list of point objects can be found in Table 2.1.7 on p. 131), groups of points (see Section 2.5.3 on p. 348 for more information about groups of points) or arrays of points (see Section 2.7 on p. 509 for more information about arrays) in the Model Tree or model window. Merge points are not allowed.

Selecting a point object or a group of points with the **Associate** option enabled will result in creation of an associative relation of the point with these objects.

You can create a point by clicking the **Point Drawing** button on the Special Control Panel (for details see Section 2.5.2.11.1 on p. 347).

The surface ghost will appear after specifying the third point. The points are numbered in the order they are preset.

The **Read from File** button enables acquiring the coordinates of points saved in a file (data file is detailed in Appendix VI). The system interprets the numbers saved in the file as point coordinates in the Cartesian coordinate system which coincides with the surface coordinate system (for more information about the object coordinate system see Section 2.8.3.4 on p. 597). The points imported from a file are added to the already specified points with the ghost reconstruction.

To cancel selection of one or several final points click the **Cancel Selection** button on the Special Control Panel. To specify another reference point, click the **Select Other** button.

If at least one point of a surface is specified, the **Edit** button becomes available on the Advanced Control panel. Enables surface edit mode (see Section 2.6.1.7.4 on p. 457).

2.6.1.7.3. Recognition of Point Grid

There are three methods of point recognition available. All the methods imply searching for grid cells — directly in space or in the plane. After all the points are projected onto a plane the system will search for cells formed by the point projections.

Cells shape depends on the type of the surface: Cells of surface **By Points** or **By Poles** are quadrangular, cells of **Polyface Surface** — triangular.

If the search returns any cells on the surface they are used for allocating cells in space.

Triangular cells, unlike quadrangular, can always be found.

If the search fails to find any rectangular cells in space or on the surface the grid is built in such a way that each row of one direction passes through a formation point whereas in the second direction the grid has two rows.

The **Method** group of switches is used to select the method of recognizing the grid formed by the formation points.

- ▼ If the **Automatic** recognition method is selected the system first searches for grid cells in the space. If the search returns no results, the system continues to search for cells on the surface the position of which is determined automatically based on the relationship of the formation points.

- ▼ If the **In Coordinate System Plane** option is enabled, the system will search for cells in XY plane of the coordinate system specified by the user. If this switch is enabled the list of coordinate systems becomes accessible on the Properties bar.

- ▼ If the **In Screen Plane** method is selected, the system will search for cells in the plane parallel to the screen - i.e. the surface shape will depend on the model position relative to the observer. Enabling this switch reveals the **Fix Position** option on the Properties bar. Enabling this option fixes the surface in the form corresponding to the current position of the model. With the option disabled the surface will be reconstructed each time after changing the model orientation. Note that the surface form (especially, polyface) can change sharply in case of a relatively small change of the model position.

The following order of point grid detection is recommended.

1. Use **Automatic** determination method
2. If the automatic recognition result is unsatisfactory, use the **In Coordinate System Plane** and **In Screen Plane** to pick up suitable plane for points projecting.
3. If you do not get the required form of the surface using these methods, edit the point layer: create additional points (see Section 2.6.1.7.2), exclude or move points (see Section 2.6.1.7.4).

2.6.1.7.4. Surface Editing Mode Along Point Formation

To switch to the editing mode click the **Edit** button on the Advanced Control panel.

Property toolbar contains controls shown in Figure 2.6.13.

Fig. 2.6.16. The Properties bar while editing a surface along a point grid

The system automatically switches to the surface editing mode on running the edit command for an earlier created surface. In this case the Properties bar differs from the one shown on Fig. 2.6.13 by the lack of the **Result - Along Point Grid** option, i.e. transforming an already existing surface created along a point formation into a surface along a point grid is impossible.

The editing mode enables changing the position of points as well as deleting them. To specify the point to be edited click it with the mouse in the model window.

- ▼ To set a new point position, specify a new point object or drag the or select other point construction method (for more details refer to paragraph 3, Section 2.5.2.11.2 on p. 347).

- ▼ To delete a point click the **Delete Point** on the Advanced Control panel.

Other controls accessible in the surface editing mode function identically to the surface creation mode (see Section 2.6.1.7.1).

All updates shall be displayed on the LCS ghost in the model window.

To continue designation of the grid points after editing the surface release the **Edit** button. To stop surface creation, click the **Create Object** button.

2.6.1.8. Surface Along a Curve Grid

The surface along a curve grid is a spline surface built along two intersecting families of curves. The curve intersection points are called **grid nodes**.

All curves of the first family are considered U direction curves, while all curves of the second family are considered V direction curves. Points can be specified for one direction as one or two end curves.

Fig. 2.6.17. Surface Along Curve Grid.
u1, u2, u3 are the curves of direction U whereas v1, v2, v3 are the curves of direction V.
The grid nodes are marked with circles

2.6.1.8.1. Curves and grid points

Curves and grid points collocation requirements:

- ▼ Each curve of one direction shall have one common point with each curve of other direction.
- ▼ Collocation of curves having different directions is inadmissible.
- ▼ Curves of the same direction shall be either closed or opened.
- ▼ The points can be specified instead one or both end curves in any direction. In this case, all curves of other direction shall pass through the point(s) specified for this direction.

The curves forming the grid may be represented by any single-segment spatial curves, edges and sketch lines, whereas points may be represented by any point objects.

2.6.1.8.2. Construction of Surface Along Curve Grid

To create a surface by the curve grid, call the **Surface by Curve Grid** command. Control elements for joining curves will appear on the Properties Bar (Fig.2.6.18).

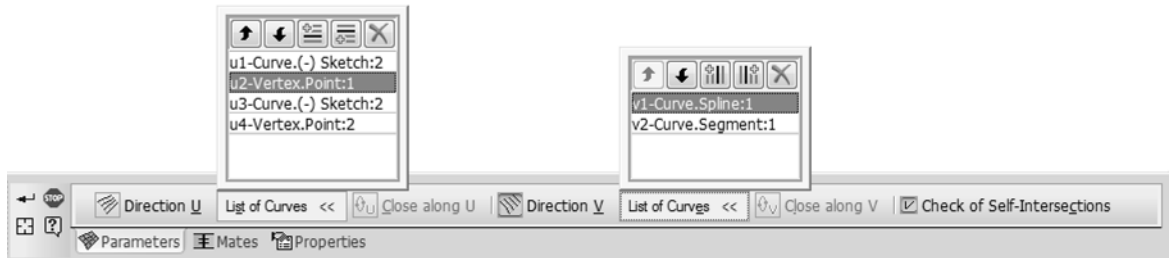

Fig. 2.6.18. Property Bar for constructing surface by curve grid

Switch **Direction U** is enabled automatically. Select objects for U direction— curves and curves and points with reference to their sequence order on the grid. Minimum two curves, or one curve and a point, or one curve and two points shall be specified for this direction. The corresponding direction of creation can be selected from the **Direction** list in the Property bar. The model window displays the surface ghost.

For V direction you may select no curve, or select one or several curves. If no points are selected for U direction, it is possible to specify points for V direction.

If one curve is preset for V direction, such curve shall pass through end (start of final) points of all U curves.

To select the V direction objects, enable switch **V direction** on the Property bar and select the required objects with reference to their sequence order on the grid. They will be added to the **V direction curves** list.

The control buttons of the list elements are located above the curve lists.

- ▼ To change position of a curve in the list select it and click button **Move up** or **Move down**.

- ▼ To add a curve before or after the specific curve in the list, select the curve in the list, click the **Insert button before the curve** or **Insert after the curve**, then specify the curve to be added.

- ▼ To remove any curve from the list, select it and click **Delete**.

If you need to clear both curve lists, click the **Reselect** button on the Special Control panel.

Switches **Close by U** and **Close by V** allow to close the surface. The surface becomes closed in either direction if all curves of the same direction are closed.

If the surface can be closed in any direction, the corresponding switch is accessible.

If you want to check surface for self-crossing, enable the **Check self-crossing** option.

If the created surface links up with an existing one, you may preset mating conditions for the created surface. The mating conditions can be preset in the **Mating** tab of the Property bar (see Section 2.6.1.8.3).

All surface modifications are displayed on its ghost in the model window.

You can define the surface name and color on the **Properties** tab of the Property bar.

To finish construction of curves and save the preset surface properties, click the **Create Object** button on the Special Control Panel.

The created surface will appear in the model window, and the surface icon — in the Design Tree.

End curves or points are boarders for the created surface. If no (or one) curve is selected for V direction, the surface boarders (of one of the boarders) in this direction will be determined in automated mode.

If the **Self-Intersection Check** option was enabled and returned a positive result the surface will be marked in the Design Tree with an exclamation mark in a red circle which indicates errors. For more information about self-intersection of surface refer to Section 2.6.1.6.5.

2.6.1.8.3. Mating surface with other surfaces

Conditions for mating a surface with other surfaces existing in the model shall be specified during surface creation or edition on the **Mating** tab of the Property bar (Fig.2.6.19).

Fig. 2.6.19. **Settings** tab

The created surface can be mated with existing ones along its boarder. In order to perform a mating operation the boarder shall be created as a directly specified curve (i.e. it shall neither be a point nor determined automatically).

Surface boarders available for mating are called **mating boarders**, and in-model surface which is engaged in mating with the create one— **mating surface**. The mating surface shall have a full-length mating boundary. The following may be used as mating surfaces:

- ▼ faces of bodies and surfaces,
- ▼ auxiliary and coordinate planes.

There are three mating conditions available: **Not Specified**, **By Tangent** and **Perpendicularly** (see Section 2.5.1.7).

If the grid contains no curves opposed to the mating boarder (i.e., the curves having common points with the mating boarder), any of the three mating conditions become available for such boarder.

If opposite direction curves exist, all of them shall be perpendicular to the mating surface (**perpendicular** mating), or tangent (in case of mating **by the tangent**). If the opposite direction curves are arranged arbitrary with respect to the mating surface, there is only one mating condition - mating **Not Specified**.

Generally, surface constructed by grid points has 4 boarders, that is why group **Border number** comprises 4 switches (see Fig. 2.6.19). Among them only those are enabled that correspond to the respective mating boarders. Their numbers are displayed in the model window next to the boarders.

To create mating along any mating boarder complete the following steps.

1. In group **Units make** active one of switches. The border will be highlighted in the model window.
2. Select the mating surface in the model window. Name of the guide object will appear in the **Mating Surface** field.
3. Select a mating condition from the **Condition** list. Conditions that can not be applicable to the current boarder are unavailable.

The ghost of the surface being created will move in the model tree in accordance with the selected mating condition; identification of the mating condition will appear near the boarder number.

2.6.1.9. Ruled Surface

A ruled surface is constructed by moving a straight line in space.

KOMPAS-3D allows building a ruled surface along two guide elements one of which may be represented by a point. Some examples of ruled surfaces are given on the figure 2.6.20; the guide curves are marked with a thickened line whereas the guide point is marked with a circle.

Fig. 2.6.20. Ruled surfaces:
a) along guide curves, b) along a guide curve and a guide point

2.6.1.9.1. Creating a Ruled Surface

To create a ruled surface, click the **Ruled Surface** command. Guideway controls will become available on the Property bar.

Available guideway controls:

- ▼ a 3D curve,
- ▼ a sketch line,
- ▼ an edge,
- ▼ Chain of objects listed above in any combination,
- ▼ a point object.

The objects belonging to 3D curves and point objects are listed in Table 2.1.7 on p. 131.

After calling the command the **Curve 1** switch will be automatically activated.

Specify an object or objects to be used as the first guideway. The thread of 3D curves should be specified in the order of their connection. Name of the selected object or number of objects in the selected succession will appear in field **Curve 1**.

Enable switch **Curve 2** and, following the procedure specified above, select an object or objects to be used as the second guide.

The ghost surface with numbered edges will appear on the screen. The guides are marked with boxed numbers 1 and 2.

To change any of the objects enable the corresponding switch and re-select the object.

To specify a point instead of a curve deselect the curve, and visa versa.

To cancel selection of all the objects click **Re-select** button on the Advanced Control panel.

If you want to check surface for self-crossing, enable the **Check self-crossing** option.

Tab **Split** on the Property bar allows to set split rules surface by faces (see Section 2.6.1.9.2).

Tab **Properties** serves to define the surface name and color.

Selection of guide lines and preset of surface properties finished, click **Create Object** on the Special Control Panel.

The created surface will appear in the model window, and the surface icon — in the Design Tree.

If the **Self-Intersection Check** option was enabled and returned a positive result the surface will be marked in the Design Tree with an exclamation mark in a red circle which indicates errors. For more information about self-intersection of surface refer to Section 2.6.1.6.5.

2.6.1.9.2. Managing Surface Splitting into Faces

By default a ruled surface is split into surfaces automatically - i.e. the number of transversal ribs and the position of their vertices are system-defined.

If one of the guides is a point whereas the other is a single-segment 3D curve, and also in case both the guides are such curves, the surface has two extreme edges — the initial and the final ones. If at least one of the guides is a multi-segment 3D curve or a thread of curves, the surface is split into faces by the edges each of which originates from the guide vertex.

If necessary, the user may change the settings of face splitting into edges. In the example shown on Fig.2.6.21 one automatically generated edge was deleted whereas the vertices of the other two were combined with the guide vertex.

Fig. 2.6.21. Surface splitting into faces: a) automatic, b) user defined

Surface splitting into faces is set up using the **Splitting** tab of the Properties bar.

If option **Auto Determination** is enabled, the surface will be split by faces in automated mode. If the guide has the same number of vertices, you may enable the **By Vertices** option — a surface will be created so that corresponding vertices of guides were connected by edges. With the option disabled the surface with minimum curvature is created. If the number of vertices of guides is different, status of the option does not affect the shape of surface.

To edit the splitting settings disable the **Autodefine** option. Controls for the split process will appear on the **Split** tab (Fig. 2.6.22).

Fig. 2.6.22. **Splitting** tab

Panel **List of Edges** contains numbered list of the surface edges.

When you select a row in the **List of Edges**, the corresponding edge is highlighted in the model window and vice versa, when you select an edge, the row corresponding to this edge is highlighted in the list.

The user may delete and add edges and move edge vertices along the guides, as well as create or cancel the associative relation with the guide vertices as necessary. All the changes will be reflected in the surface ghost.

Absence of the ghost indicates nonexistence of surface. Typical reasons for this are:

- ▼ Matching or intersection of edges;
- ▼ Absence of edges originating from the intermediate vertices of the guides.

Delete Edge

1. Select an edge.
2. Click the **Delete Edge** button on the **List of Edges** bar.
The selected edge disappears while the rest will be re-numbered.
Deletion becomes impossible if the list is reduced to two edges.

Add Edge

1. Select the edge before or after which you want to insert a new edge.
2. Click **Insert Before the Current Edge** or **Insert After the Current Edge**.
A new edge with the successive number is added to the surface.

Associative relation of edge vertices with point objects Relocation of Edge Vertices

By default edge vertices are associated with the guide vertices. The user may cancel the relations and create new ones, if necessary. The relation object may be represented by the guide vertex or a point constructed on it using the **Point** command (the **On Line, Intersection**) or **Group of Points Along a Curve**.

To set the object for mating the edge vertex:

1. Select an edge.
2. Select the edge vertex by enabling the necessary switch in the **Initial/Final Vertex** group. If the vertex is not associated, the handle will be displayed on selecting its edge. Click the handle to select such vertex.
3. Specify the guide vertex or the point on it which the selected edge vertex is to be associated with in the model window. The vertex will be matched with the specified object, and its name will appear in the **Object** field. The “tick” on the **Object** button indicates the relation of the edge vertex with the object.

To cancel the relation of a vertex with an object highlight an edge, select the vertex and click the **Object** button. The tick on the button will disappear.

A non-related vertex can be moved along the guide at will by dragging its handle with the mouse.

If the 3D line used as the guide is hidden, the edge cannot be snapped to the guide vertex.

To use only a segment of the guide instead of its entire length cancel the relation of the extreme edge with the guide vertex and then move the vertex along the guide or relate it to another object.

If one of the guides is represented by a point, the **Initial/Final Vertex** group of switches is not available whereas the relation presence or absence indicator represented by the **Object** element relates to the edge vertex which lies on the guide.

2.6.1.10. Patch

Patch — surface, limited by a closed contour. Edges of bodies and surfaces, sketch lines or 3D curves can be used as contour segments.

Segment specification is subject to the following constraints:

- ▼ The contour shall not have self-intersections.
- ▼ If segments are on the same plane or on a single existing plane, there can be any number of them; in other cases, their number is limited by two and by four.

To create a patch, apply the **Patch** command.

In the Model Tree, specify the contour segments in the sequence they are connected.

If the contour surrounding the patch is contained in one sketch, select that sketch in the Design Tree or in the Model window.

The selected objects will be highlighted in the Model window and in the Design Tree.

The list of objects making up the contour will appear on the Property bar (Fig. 2.6.23). The **Delete** button located above the bar allows deleting some object from the contour. To exclude an object, you can select it again. An excluded face becomes deselected.

Fig. 2.6.23.

If you want to check surface for self-crossing, enable the **Check self-crossing** option.

To confirm the operation click the **Create Object** button on the Advanced Control panel.

Note that the **Create Object** button is available, if the selected objects make a closed chain.

The surface created shall appear in the model window and the applicable icon — in the Design Tree.

If the **Self-Intersection Check** option was enabled and returned a positive result the surface will be marked in the Design Tree with an exclamation mark in a red circle which indicates errors. For more information about self-intersection of surface refer to Section 2.6.1.6.5 on

p. 454.

2.6.1.11. Blend Surface

You can create a surface that connects two faces. The joint surface boundaries are specified edges or chains of edges of faces to be joined. An edge chain must meet the following criteria:

- ▼ all edges belong to a single face,
- ▼ edges have a common tangent in connection points.

Fig. 2.6.24. Surface, that connects two flat faces

The joint surface is mated with the edges along boundaries. Several mate options are available. You can change the form of a joining surface by means of tension parameter. In addition, you can control the shape of surface lateral edges.

Do the following to create a blend surface.

1. Start the surface creation operation. To do this, click the **Blend Surface** button of the **Surface** panel or call the **Operations — Surface — Blend Surface** command.

2. The system expects indicating the first surface of the surface to be created — in the group **Select boundary**, the **Boundary 1** switch is enabled.

Select the first border in the model window— an edge or chain of edges. Select chain in compliance with edges connection order. Name of the selected edge (or number of edges in a chain) appears in the **Border Curve 1** field. The border is highlighted in the model window, ID number and default mating condition icon are displayed near it.

Set the parameters of the blend surface along its first boarder.

Fig. 2.6.25. Control elements for blend surface parameters of the Properties bar

2.1. Mating surface

As the mating surface, the face with the indicated boundary is selected. The face is highlighted in the model window, its name appears in the **Surface 1** field. If its edges simul-

taneously belongs to two faces, you can change the face. For this, specify the required face in the model window.

2.2. Mating condition and direction

Select the mating condition of the blend surface with the mating surface from the **Condition** list. The following mating conditions are possible: not specified, by tangent, perpendicularly and smooth (see Section 2.5.1.7 on p. 332).

The **Change Direction** switch allows changing mating direction to a reverse one. Meanwhile, the joint surface form near the boundary will change while the mating condition remains the same.

2.3. Tension

This parameter has an effect on a surface form: the more the tension, the more the curvature of the blend surface near the border, and vice versa, the less the tension, the less the curvature. Tension is set as percentage, from 0 to 100.

Enter the tension value in the **Tension, %** field.

2.4. The position of lateral edges

Side edges of the joint surface can be continuations of side edges of surfaces to be joined. They also can be perpendicular to the boundary (Fig. 2.6.26).

Fig. 2.6.26. Lateral edges of the blend surface:
a) extensions of lateral edges of mated surfaces;
b) are perpendicular to borders

To select a variant of creation of side edges near the first boundary of the joint surface, enable the required switch in group **Side edges**.

3. If you need to use the same tension value for the second border as for the first, enable the **General Tension** option. In this case, when changing tension for one of the boundaries, tension of another is also changed automatically.

4. In the **Boundary selection** group, activate the **Boundary 2** switch. Specify the second border and set the joining parameters along it in the model window— as well as the first border and the joining parameters along it.

The ghost of blend surface with the current parameters appears in the model window. Handles of the ghost allow to change surface tension on the borders.

The second boundary may be of the same face as the first one — the surface will built automatically to connect different edges of one face.

5. If you want to check surface for self-crossing, enable the **Check self-crossing** option.

6. If necessary, you can customize the blend **surface splitting** into faces — move, add or delete surface edges. Enable tab **Splitting** of the Property Bar. Setting up the joint surface splitting is similar to setting up splitting of a linear surface (see Section 2.6.1.9.2 on p. 462) with the only exception: while working with a blend surface the **By Vertices** option is not active.
7. If necessary, change the name and properties of the created surface. Enable the **Properties** tab of the Property Bar.

8. Confirm surface creation. To do this, click the **Create Object** button on the Advanced Control panel.

The created surface will appear in the Model window and its icon will show in the Design Tree. If the **Self-Intersection Check** option was enabled and returned a positive result the surface will be marked in the Design Tree with an exclamation mark in a red circle which indicates errors. For more information about self-intersection of surface refer to Section 2.6.1.6.5 on p. 454.

2.6.1.12. Equidistant Surface

The user may build a curve equidistant to the base one.

The following objects can be used as a base surface.

- ▼ face of the body or surface,
- ▼ Connected set of faces of the same body or surface (see Section 2.5.1.1 on p. 327).

Fig. 2.6.27. Equidistant Surface:
a) Base surface— surface face;
b) Base surface— set of faces

To create an equidistant surface run the **Equidistant to Surface** command.

Specify the base surface in the model window.

If the body/surface faces are used as the base surface, such body/surface can be selected in the Design Tree.

The base surface may be also selected before the command selection.

Second selection of the base surface cancels its selection.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

The name of the selected object or the number of selected objects are shown in the **Surface** field.

The equidistant surface ghost with the handle for setting the distance from the base surface to the one being created is displayed on the screen (handles are detailed in Section 2.1.4.2.2).

To specify which side of the base surface the equidistant surface will be created enable the **Forward Direction** or **Reverse Direction** switch in the **Direction** group.

Set the distance from the base surface to the one being created by entering it into the **Distance** field on the Properties bar.

All the parameter changes will be displayed on the ghost of the surface being created in the model window.

To change the base surface click the **Re-select** button on the Advanced Control panel and re-select the object or objects.

The **Properties** tab enables setting the name and color of the surface being created.

To finalize construction of the equidistant surface, click the **Create Object** button on the Special Control Panel.

The surface which has been created will appear in the model window and its icon will show in the Design Tree.

At zero shift the equidistant surface copies the base surface. Thus, it is possible to create the required quantity of copies of the surface being base for a few bodies or parts.

2.6.2. Surface editing

2.6.2.1. Surface Trimming

The user may trim a part of the surface or make a cut the shape of the objects lying on the surface or intersecting it (Fig. 2.6.28). Trimming may also follow a contour projected onto the selected surface (see Fig. 2.6.29).

Fig. 2.6.28. Truncate surface using another surface:
a) Surfaces before trimming; b) Trimming result

2.6.2.1.1. Requirements to Objects of the trimming operation

The **trimmed surface** may be represented by a connected set of faces of the same body or surface. When specifying an object in the Design Tree the trimmed surface is formed using all the faces of the object.

The options for **cutting objects** are given in Table 2.6.1. The cutting objects must unambiguously determine the truncation boundary - i.e. completely cross the trimmed surface.

In case of a polyface trimmed surface, the trim boundary is also considered fully defined, if the trimming object intersects one or several faces (not all of it) but in such a way that outermost points of the intersection line are located on the edges of these faces. In this case, edges or parts of surface edges are included in the trimming boundary, see Fig. 2.6.30.

Tab. 2.6.1. Cutting objects while trimming a surface

Cutting Object	Usage Details
Coordinate or Auxiliary Plane	Trimming follows the line of intersecting the plane and the trimmed surface.
Connected set of faces of the same body or same surface	Trimming follows the line of intersecting the cutting object and the trimmed surface. When specifying an object in the Design Tree the cutting object is formed using all the faces of the selected object.
Curve on Trimmed Surface:	Trimming follows a curve.
▼ a 3D curve,	A 3D line may represent the cutting object only if this curve is directly initial or directly derivative * in relation to the trimmed surface.
▼ solid or surface edge,	
▼ Chain of curves or edges.	<ul style="list-style-type: none"> ▼ Example of using a source curve: cutting a surface built along a curve grid (see Section 2.6.1.8 on p. 458), by one of the curves. ▼ Example of using a derivative curve: cutting the surface along the equidistant curve built by offset along the trimmed surface (equidistant curves are covered in Section 2.5.4.17 on p. 417).
Sketch	Trimming follows the line of intersecting the trimmed surface and the surface produced by extruding a sketch perpendicularly to its plane (see Fig. 2.6.29). The sketch must be specified in the Design Tree. A sketch may contain one open contour or multiple closed contours. The contours must not self-intersect.

* In other words the hierarchy of the relations between the curve and the trimmed surface must not contain any other objects (viewing object relations is covered in Section 2.1.2.7.2 on p. 114).

Model object selection is detailed in Section 2.1.4.1.1 on p. 130.

Fig. 2.6.29. Example - Truncation of surface using the sketch contour:
a) surface to be truncated and secant object, b) objects after selection, c) truncation result

Fig. 2.6.30. Example of triangular surface trimming:
a) surface to be truncated and secant object, b) truncation result

2.6.2.1.2. Trimming Operation

To trim a surface run the **Surface Trimming** command. The command is accessible if there is at least one body or surface in the Model.

The trimming controls will appear on the Properties bar (Fig. 2.6.31).

Fig. 2.6.31. Properties bar while trimming a surface

The **Surface** switch is enabled automatically. Specify the faces forming the trimmed surface in the model window. The surface object or body can be selected in the Design Tree.

Surface to be truncated can be also selected before calling the command.

To specify the object the intersection with which defines the line of plane truncation, enable the **Secant Object** switch.

Specify the secant object(s) in the model window or in the Design Tree.

If it is required to trim a surface along the isoparametric curve, this curve may be built without leaving the trimming process. To do this, click the **Isoparametric Curve** button on the Advanced Control panel. The isoparametric curve on the surface creation operation will be started (see Section 2.5.4.18 on p. 422). If the trimmed surface consists of one surface, it is selected automatically. In case of several surfaces, you should specify the face on which the curve should be positioned. After that, specify the point on face, choose the direction of isoparametric curve passing through it, and click the **Create Object** button. The system will resume the trimming operation process, created curve will appear in the Design Tree and will be automatically selected as a secant object.

Trimmed surface and secant object are highlighted and their names appear in the **Surface** and **Secant Object** fields.

The arrow pointing to the surface part to be cut is displayed at the object intersection line.

The **Change Direction** switch allows to select another part of the trimmed surface to be truncated.

To deselect an object as an object to be truncated or a secant object, enable the **Surface** or **Secant Object** switch respectively, and reselect an object in the Model window. Highlighting will be cleared off the object.

To cancel selection of all the objects click the **Re-select** button on the Advanced Control panel and re-select objects.

The name of the trimming operation can be edited in the **Properties** tab of the Property bar.

To complete surface trimming, click the **Create Object** button on the Special Control Panel.

The **Create Object** button will become unavailable if the selected objects fail to meet the criteria (see Section 2.6.2.1.1 on p. 469).

The truncated surface will be displayed in the model window and the corresponding icon — in the Design Tree.

If the user has specified a body or its faces as the trimmed object, the trimming operation may cause disintegration of the body. For details on bodies with broken integrity, see Section 2.6.2.6 on p. 480.

2.6.2.2. Surface splitting

You can split a surface or body faces into several new faces. With this, the model gets additional edges representing the boundaries of the newly generated facets (Fig. 2.6.32). Surface splitting can be done:

- ▼ by curves on surface,
- ▼ by the lines of intersection with other surfaces or planes,
- ▼ by contours, projected to the surface.

Fig. 2.6.32. Using an edge resulting from face's splitting:
a) initial state of a part, b) result of a rounding by maintaining "cliff" edges

2.6.2.2.1. Requirements to Objects of the splitting operation

As a **surface to be trimmed**, you can use any set of faces, bodies, and/or surfaces. When specifying an object in the Design Tree the split surface is formed using all the faces of the object.

The options for **cutting objects** are given in Table 2.6.2. The cutting objects must unambiguously determine the split line - i.e. completely cross the split surface.

In case of a polyface trimmed surface, the splitting line is also considered fully defined, if the trimming object intersects one or several faces (not all of it) but in such a way that outermost points of the intersection line are located on the edges of these faces. In this case, the operation will result only these faces splitting.

Tab. 2.6.2. Cutting objects while trimming a surface

Cutting Object	Usage Details
Coordinate or Auxiliary Plane; Face	<ul style="list-style-type: none"> ▼ Trimming follows the line of intersecting the plane or face and the splitted surface. ▼ You can use any set of planes and/or faces.
Curve on Split Surface:	<ul style="list-style-type: none"> ▼ Trimming follows a curve.
<ul style="list-style-type: none"> ▼ projection, ▼ isoparametric, ▼ intersection line, ▼ outline line, ▼ spline on surface 	<ul style="list-style-type: none"> ▼ You can use arbitrary set of curves. ▼ Curves can intersect but must not have self-intersect.

Tab. 2.6.2. Cutting objects while trimming a surface

Cutting Object	Usage Details
Sketch	<ul style="list-style-type: none"> ▼ Trimming follows the line of intersecting the trimmed surface and the surface produced by extruding a sketch perpendicularly to its plane. ▼ You may use only one sketch. ▼ Sketch objects can be a part of arbitrary number of closed and/or open contours. Contours can intersect but must not have self-intersect.

Model object selection is detailed in Section 2.1.4.1.1 on p. 130.

2.6.2.2.2. Splitting performing

To split a face (faces) of a surface or a solid, apply the **Split surface** command. The command is accessible if there is at least one body or surface in the Model.

The splitting controls will appear on the Properties bar (Fig.2.6.33).

Fig. 2.6.33. Properties bar while splitting a surface

The **Surface** switch is enabled automatically. Specify the faces forming the splitted surface in the model window. The surface object or body can be selected in the Design Tree.

The surface to be split may be also selected before the command selection.

To specify the object the intersection with which defines the line of plane splitting, enable the **Secant Object** switch.

Specify the secant object(s) in the model window or in the Design Tree.

If it is required to split a surface along the isoparametric curve, this curve may be built without leaving the trimming process. To do this, click the **Isoparametric Curve** button on the Advanced Control panel. The isoparametric curve on the surface creation operation will be started (see Section 2.5.4.18 on p. 422). If the splitted surface consists of one surface, it is selected automatically. In case of several surfaces, you should specify the face on which the curve should be positioned. After that, specify the point on face, choose the direction of isoparametric curve passing through it, and click the **Create Object** button. The system will resume the splitting operation process, created curve will appear in the Design Tree and will be automatically selected as a secant object.

Split surface and secant objects are highlighted and their names appear in the **Surface** and **Secant Object** fields. The ghosts of edges to be formed during splitting will appear in the model window.

If a sketch is selected as the secant object, the **Projection Direction** group of switches appear on the Properties bar and allow to set up the direction, in which the sketch will be moved to generate the secant surface. Activate the desired switch: **Both Directions**, **Forward Direction** or **Reverse Direction**. If direct or reverse movement direction is selected for the sketch, the direction is shown by an arrow on a ghost in the model window.

All contours of the specified sketch take part in the trimming operation. You cannot use separate contours.

To deselect an object as an object to be split or a secant object, enable the **Surface** or **Secant Object** switch respectively, and reselect an object in the Model window. Highlighting will be cleared off the object.

To cancel selection of all the objects click the **Re-select** button on the Advanced Control panel and re-select objects.

The name of the splitting operation can be edited in the **Properties** tab of the Property bar.

To complete surface splitting, click the **Create Object** button on the Special Control Panel. Selected faces are split into several faces, and in the Design Tree the surface splitting operation icon appears.

2.6.2.3. Surface Extension

The edge of a surface or the face of a body suffered from disintegration beyond the boundaries of the specified edges of the face — open edges - may be extended (open edges are detailed in Section 2.6.2.4 on p. 478).

The extension operation changes positions of or sets new faces adjacent to the specified borders.

A face is extended over the specified borders for the preset distance or up to the specified point object.

Fig. 2.6.34. Face Extension

To extend a face run the **Surface Extension**.

Select a face boarder(s) in the Model window. If you need to extend a face over all boarders, select this face.

The face or its borders can be selected in the Model window prior to calling the respective command.

The extension ghost with a handle for setting the face extension value will appear on the screen (handles are detailed in Section 2.1.4.2.2).

To cancel object selection, re-select it.

The object selection is detailed in Section 2.1.4.1.1 on p. 130.

The name of the selected object or the number of selected objects are displayed in the field next to the **Edges** switch on the Properties bar.

The **Extension Type** group of switches enables selection of the face extension type: by the same surface, tangentially or in the direction (see Section 2.6.2.3.1 on p. 476).

The **Method** drop-down list enables selection of the face extension method (see Section 2.6.2.3.2 on p. 478).

All changes are displayed in the extension ghost in the model window.

To change objects used for the face extension, click **Reselect** button on the Special Control Panel and re-select objects.

Controls in the **Property** tab of the Property bar set the object' name and color.

To finalize face extension click the **Create Object** button on the Advanced Control panel.

The face extension will appear in the model window and its icon will show in the Design Tree.

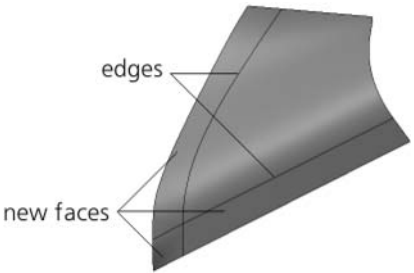

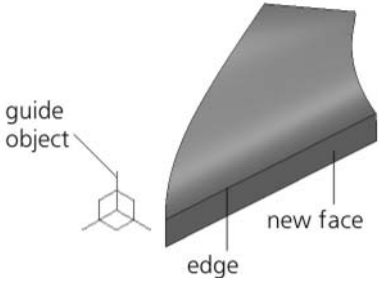

2.6.2.3.1. Extension Type

To select the face extension type, enable the desired switch in the **Type** group (Table 2.6.3).

Tab. 2.6.3. Extension Types

Extension Type	Construction result	
	<p>By the same surface</p> <p>This face extension type is set by default. In this case the face is extended without adding any new faces — the face is extended beyond the open edges along its theoretical surface (theoretical surface is detailed in Section 2.5.1.3 on p. 328). The user may choose the position of the lateral extension edges (see below).</p>	

Tab. 2.6.3. Extension Types

	Extension Type	Construction result
	<p>By Tangent Extension is performed by creating new faces tangential to the source face along the designated edges. The user may choose the position of the lateral extension edges (see below).</p>	
	<p>In the Direction Extension is performed by creating new faces formed by moving the designated edges in the specified direction. The direction is set by the guide object or vector (see below).</p>	

Position of Lateral Extension Edges

If the user has chosen the **By Same Surface** or **Tangentially** face extension method, the following options of its side edges are available: extension of source side edges or extension along the normal towards selected boards.

The various position of lateral edges are shown on Fig. 2.6.35. The dotted line corresponds to the edge beyond which the face is extended.

Fig. 2.6.35. Various positions of lateral edges: a) source object, b) extension of the original lateral edges, b) extension along the normal toward the specified edges

To select the position of lateral edges use the **Lateral Edges** group of switches. Activate the desired switch:

▼ **Extension of the Source Side Edges;**

▼ **Along the Normal to Selected Boards.**

Specifying Extension Direction

Any straight or flat object can be used as the guide object to extend a face. Straight and flat objects are listed in Table 2.1.7 on p. 131.

Direction, defined by a straight object — line, parallel to the object.

Direction, defined by a plane object — line, perpendicular to the object.

Moreover, the guide object may be represented by a vector. Such vector can be created by means of **Vector drawing** command (see Section 2.8.5 on p. 613).

To preset the face offset direction specify a guide in the Design Tree or construct a vector.

The name of the selected object shall be displayed in the field beside the **Direction** switch. If the direction is set by means of a vector, the field will contain the word “Vector”.

To change the guide object, enable switch **Direction** and reselect a new guide object or construct a vector.

The **Change Direction** switch enables reversing the edge extension direction.

2.6.2.3.2. Extension Method

Two edge extension methods are available:

- ▼ **To Specified Length** — the edge is extended beyond the specified boundaries to the specified distance;

- ▼ **Toward Vertex** — the edge is extended beyond the specified boundaries toward the selected point object.

Select the extension method using the **Direction** list on the Property bar.

- ▼ If the **To Specified Length** method is selected, the **Length** field will appear on the Properties bar.

Enter the desired extension value in the field.

- ▼ If the **Toward Vertex** method is selected, the **Vertex** control will appear on the Properties bar.

Specify the desired point object in the Model window (point objects are listed in Table 2.1.7 on p. 131). The name of the selected object shall be displayed in the field beside the switch.

To change the point object enable the **Vertex** switch and specify the desired object in the model window.

2.6.2.4. Surface Knitting

KOMPAS-3D enables joining of open edges of a single or multiple surfaces (Fig. 2.6.36 a, b) resulting in the formation of a whole surface and attachment of the surface (surfaces) to the open edges of the body (Fig. 2.6.36, c) with broken integrity. For details on bodies with broken integrity, see Section 2.6.2.6 on p. 480.

Fig. 2.6.36. Examples of open edges (marked with black color): a) revolution surface, b) extrusion surface, c) a body with broken integrity

To join the surfaces, apply the **Surface Knitting** command.

In the model window select the objects to be knitted. Those will be highlighted with a color. The list of knitted objects will appear on the Property bar. Using the buttons located above the list, you can change the order of surfaces and delete them from the list.

To exclude any surface from the pattern to be knitted re-select it in the model window.

In field **Accuracy** on Property Bar you should specify a maximum gap between the edges of the surfaces to be knitted.

The **Create Solid** option allows creating a body surrounded by the knitted surfaces. If a parts with broken integrity is present in the list of knitted surfaces, then the **Create Solid** option turns On automatically and cannot be disabled.

To confirm surface knitting, click the **Create Object** button on the Special Control Panel. If the list of surfaces to be knitted contains only one object, the **Create Object** button will only be accessible with the **Create Body** option enabled.

Surfaces, whose neighboring edges' distances are less or equal to the preset accuracy value, will be integrated into a single surface. In the Design Tree, a knitting icon appears.

Once solid construction has been enabled, then the created surface shall be checked for closure. In case of success, the resulting solid body will be limited by the obtained surface, and in case of failure, the resulting body will have broken integrity.

2.6.2.5. Deletion of Faces

To delete a face (faces) of a surface or a solid, apply the **Delete Faces** command.

Select faces to be deleted in the Model window. Those will be highlighted with a color.

Number of deleted faces shall appear in similar field on tab **Parameters** of Property Bar.

To exclude some face from selected for deletion, click it in the part window again. The face will be deselected.

To confirm splitting selected faces, click the **Create Object** button on the Special Control Panel.

Selected faces will be deleted from the model.

In the Design Tree, the face deletion icon will appear.

When deleting faces of bodies, the model is marked as an error in the Tree. The reason for that is broken integrity of bodies (see Section 2.6.2.6).

2.6.2.6. Bodies with Broken Integrity

The body integrity is broken if it acquires any open edges similar to the open edges of open surfaces (see Fig. 2.6.36 on p. 479).

The following may lead to appearance of bodies with broken integrity in the model:

- ▼ Deleting body edges using the **Delete Edges** command (see Section 2.6.2.5);
- ▼ Deleting a part of the body surface using the **Surface Trimming** command (see Section 2.6.2.1 on p. 469);
- ▼ surface knitting using the **Surface Knitting** command (see Section 2.6.2.4 on p. 478), if the **Create Body** has been enabled during the operation but the connected faces did not form a closed surface.

A special icon appearing in the Design Tree instead of the whole body icon indicates loss of integrity. The model is marked as an error in the Model Tree.

Bodies with broken integrity can be edited by means of operations with surfaces — such as extension, trimming etc.

To restore integrity add surface to close the body and close them using the **Surface Knitting** command.

Please note that closing requires mating an open edge of one surface with an open edge of another surface.

Once the integrity is restored, the icon in the Design Tree will be replaced with the icon of the solid body.

The error mark in the model is displayed until the integrity of all the bodies is restored.

2.6.3. Spline form. Face customization

You can edit a selected part's face by transforming it into a spline surface. To do so, use the special customization mode which makes it possible to customize the form and the position of the selected face. In Fig. 2.6.37, you can see an example of the face's form changing in the special customization mode.

Fig. 2.6.37. Face customization:
a) face's original state, b) customization result

In order to enter the face customization mode, call the **Spline form** command.

The compact bar's appearance will change. It will contain buttons for switching between the two toolbars: **Spline form** (enabled by default) and **Filters**. The **Spline form** button is enabled on the **Spline form** toolbar, while the Property bar contains buttons of the Special Control Panel.

Select with the cursor the part's face that needs to be edited.

The edge can also be specified before calling the **Spline form** command.

The specified face will be transformed into a spline surface¹ and highlighted (for more information about the spline surface refer to Section 2.5.1.4 on p. 329). Ghost grid created on the basis of the parametric area of the surface (see Section 2.5.1.3 on p. 328) will be displayed on the screen. The grid is formed by rows of points – poles. The rows of the grid are located in two directions — U and V. When changing the poles positions, the form and/or the position of the edge may change.

If necessary, you can edit the equidistant surface of the selected face (not the face itself). See Section 2.6.3.5 on p. 505.

Note that when editing an existing face, boundary forms of its adjacent faces may change, while the equidistant surface is a separate object. Therefore, its customization does not change the boundaries of the part's faces.

The following actions can also be performed in the face editing mode:

- ▼ changing the form and the position of a face by moving poles using the toolbar commands (see Section 2.6.3.1 on p. 482) or by the mouse (see Section 2.6.3.4 on p. 503)
- ▼ fixation of grid poles and boundaries of the customized face (see Section 2.6.3.2 on p. 499),
- ▼ changing spline form parameters (see Section 2.6.3.3 on p. 501).

1. As a result of the transformation, the face will lose its initial properties. For example, after transformation of a conical face into a spline face, construction of its axis using the **Conical surface's axis** command will become impossible.

You can cancel performed operations or redo the last canceled operation (see Section 1.4.1.6 on p. 79).

Besides that, you can redefine the object for editing by selecting another edge for editing using the **Reselect** button of the Special Control Panel. Note that all modifications of the edge and its equidistant, made before object reselecting, will be lost.

In order to complete face editing, click the **Create object** button. Working in the edge editing mode will be finished, and all changes will be saved. An icon appropriate for the **Spline form operation** will appear in the Design Tree.

The **Interrupt command** button makes it possible to leave the editing mode without saving the changes.

2.6.3.1. Changing poles positions

To change grid poles positions, the following commands of the **Spline form** toolbar are used:

▼ **Linear displacement,**

▼ **Displacement with smoothing,**

▼ **Rotation,**

▼ **Scaling,**

▼ **Alignment.**

You can use these commands to move individual poles or all poles in the selected row. Details about the selection of poles can be found in Section 2.6.3.1.1 on p. 483.

When changing the poles positions, the form and/or the position of the face may change. If the new position of poles does not ensure correct changing of the face's form or position, the face remains in its initial state (refer to Section 2.6.3.6 on p. 507 for more details).

Depending on the command, poles' displacement is defined by different parameters: offset value, rotation angle, scaling coefficient and so on. However, each of the above-mentioned commands requires displacement direction setting. Typical displacement direction variants are described in Table 2.6.4. Special variants that are used with certain commands are described in their respective sections.

Tab. 2.6.4. Pole displacement direction variants

Variant	Description
Along the X axis	Direction is defined by X, Y, or Z axis of the current coordinate system (see Section 2.8.3.3 on p. 597).
Along the Y axis	
Along the Z axis	

Tab. 2.6.4. Pole displacement direction variants

Variant	Description
Parallel to Object	<p>Direction is set by specification of an object of one of the following types: straight-line object (see Table 2.1.7 on p. 131), cylinder, cone, toroid.</p> <p>In case of a straight-line object selection, the direction will coincide with it.</p> <p>In case of a cylinder, cone or toroid selection, the direction will coincide with its axis.</p> <p>Specify the required object in the Design Tree or Model Window. The name of the object is displayed in the Guiding Object field.</p> <p>In case of poles movement by rotation, scaling or alignment, the Guiding object switch will be present on the Property bar. Use it to change the guiding object, if necessary.</p>
Perpendicular to Object	<p>Direction is defined by specifying a custom flat object (see Table 2.1.7 on p. 131) and coincides with the perpendicular to the object. After selection of this object, select the desired object in the Design Tree or in the model window. The name of the object is displayed in the Guiding Object field.</p> <p>In case of poles movement by rotation, scaling or alignment, the Guiding object switch will be present on the Property bar. Use it to change the guiding object, if necessary.</p>
By Normal	<p>The direction is set by the normal to the edited edge going through the pole which is being displaced.</p>

2.6.3.1.1. Selection of poles

Depending on which command is used for displacement or fixation of poles, the poles for displacement are selected as follows.

- ▼ In order to select poles for displacement by **Rotation, Scaling, Alignment** commands, as well as for fixation using the **Fix poles** command, do the following.

Move the cursor to the required pole. As soon as the symbol of a vertex appears next to the cursor, click the mouse. The selected pole will be highlighted. Select all the required poles one by one. If a pole's selection should be canceled click it again with the mouse.

You can select individual poles and rows of poles. Selection of a row means that all poles of this row are added to the set of selected poles.

To select a row of poles, move the cursor to the segment of the row. As soon as the symbol of a 3D curve appears next to the cursor, click the mouse. All segments of the selected row will be highlighted. The repeated mouse button pressing on the row's segment cancels the selection of poles.

- ▼ In order to select poles for displacement by the **Linear displacement** or **Displacement with smoothening** command, poles or segments of pole rows should be specified by clicking the

mouse keeping the **<Ctrl>** key pressed. Another mouse click with pressed **<Ctrl>** key deselects the pole (pole row).

Poles of the selected row can also be selected individually (before or after the row selection). These poles remain selected after row's deselection.

You can select any number of poles by specifying separate poles or grid rows.

You can also use **Select all poles**, **Cancel pole selection** and **Invert pole selection** commands from the context menu to select poles.

2.6.3.1.2. Linear pole displacement

Positions of grid poles of the edited face can also be changed by linear displacement (Fig. 2.6.38).

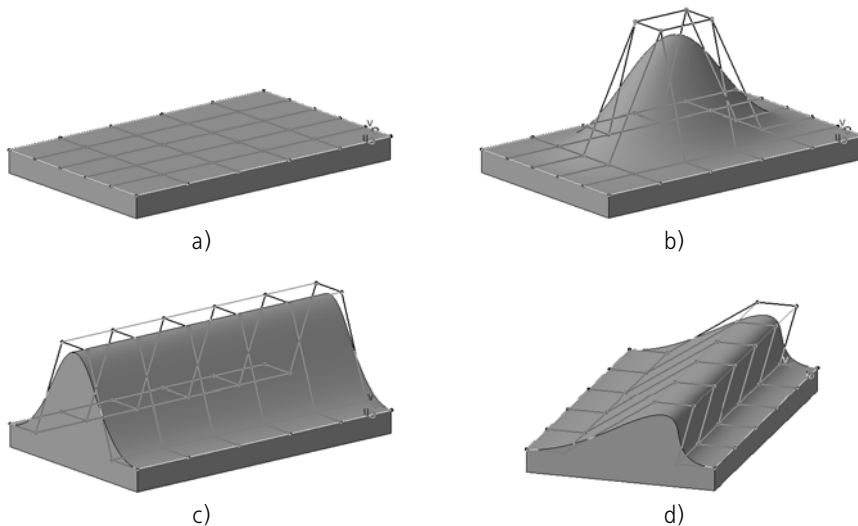

Fig. 2.6.38. Displacement of poles:
 a) face's initial state, b) displacement of poles along the Z axis,
 c) displacement of pole rows along the Z axis, d) displacement of pole rows within the screen's plane

The selected rows are moved in the required direction in accordance with certain displacement conditions.

To move objects, perform the following operations.

1. Call the **Linear displacement** command. The Property bar will display control elements for displacement parameters' settings (Fig. 2.6.39).

Fig. 2.6.39. Property bar during the displacement of poles

2. Specify poles that should be displaced (see Section 2.6.3.1.1 on p. 483).

Linear displacement of poles can be made manually or automatically.

If you need to move one pole manually (one row of poles), you do not have to specify a pole (row of poles). The displacement procedure is described in p. 5 of the current Section.

3. Select the required pole displacement direction option using the **Direction** drop-down list. The following methods are available:

- ▼ **Along the X axis,**
- ▼ **Along the Y axis,**
- ▼ **Along the Z axis,**
- ▼ **Parallel to an Object,**
- ▼ **Perpendicular to object,**
- ▼ **By normal,**
- ▼ **Along polygon,**
- ▼ **Within the screen plane.**

Description of typical displacement direction variants (**Along the X axis, Along the Y axis, Along the Z axis, Parallel to object, Perpendicular to object, By normal**) can be found in Table 2.6.4 on p. 482.

If the **Along polygon** option is selected, displacement is performed along U or V grid direction.

The **Within the screen plane** option makes it possible to move poles within the screen plane. Additional controls will become available on the Property bar after selection of the displacement direction variant. The set of these controls and further actions depend on the selected variant.

4. Make additional displacement settings in accordance with the selected variant.

- ▼ **Along the X axis/Along the Y axis/Along the Z axis** — no additional settings are required.
- ▼ **Parallel to object/Perpendicular to object** — specify the guiding object in the model Tree or window. The name of the object is displayed in the **Guiding Object** field.
- ▼ **By normal** — enable/disable the **From source** option.

If the option is enabled, the normal's position will be calculated with respect to the edited edge's source form; if the option is disabled — with respect to the current edge's form. The edge's source form is the form that the edge had at the moment of calling the **Spline form** command.

- ▼ **Along polygon** — select the direction type by enabling the **Along U** or **Along V** of the **Type** group of switches. Two offset variants are available for each direction.

- ▼ **To the next,**
- ▼ **To the previous.**

If the first option is selected, the pole will be moved along the grid's segment connecting the pole with the next pole along the U/V direction; if the second option is selected, it will be moved opposite to the U/V direction.

Activate the switch appropriate to the required variant.

▼ **Within the screen plane** — no additional actions are required.

5. Move the selected poles manually or automatically.

To move the poles manually, move the cursor to one of the selected poles. When the symbol of a vertex appears next to the cursor, move the mouse to the required position keeping the left button clicked. After that, release the button.

If selected poles include the poles that were selected by row specification, you can move the cursor to this row's segment. When the symbol of a 3D curve appears next to the cursor, move the mouse to the required position keeping the left button clicked. After that, release the button.

It is impossible to move the poles behind the row's segment, if the **By normal** movement direction is set.

To automatically move the poles, enter the offset value for the poles in the **Offset** field. The value can be both positive and negative. Once the poles have been moved, the **Offset** field will be set to zero.

For the **In the screen's plane** direction of movement, you can only use manual movement of poles.

6. When moving the selected poles manually, you can set an additional condition of the movement making it possible to move some poles of the grid adjacent to the selected one. To do this, use the **Conditions** list. The procedure of setting conditions is described in detail below.

7. To finish the command, click the **Create object** button.

Additional condition of pole displacement

In case of a manual pole displacement, you can move not only the selected poles but also a certain number of nonselected poles located in the same rows with the selected poles. The rows can be located along U and V direction of the grid, as well as in both directions (see Fig. 2.6.40).

Fig. 2.6.40. Proportional displacement of poles:
a) in the row along the U direction, b) in rows along U and V directions

Poles are moved proportionally along the same direction with the selected poles.

The offset of each poles is calculated as follows.

Let P_0 is a pole selected for manual displacement. Its offset L_0 is defined by the user.

P_i is a pole which is moved together with the selected pole,

where i is a serial number of the pole in the row. The selected pole is the starting point of pole counting. The pole which is closest to the selected one has serial number 1, the following pole has serial number 2, and so on.

The number of poles which are proportionally moved together with the selected one is set by the user and is equal to n , i.e. the first serial pole for displacement is P_1 while the last one is P_n .

Offset L_i of the P_i pole is calculated automatically. The calculation is made in accordance with the formula:

$$L_i = L_0 \cdot (n + 1 - i) / (n + 1)$$

Thus, for example, in case of a proportional displacement of 3 poles (Fig. 2.6.41), the offset of each of them will be as follows:

$$L_1 = L_0 \cdot (3 + 1 - 1) / (3 + 1) = L_0 \cdot 3 / 4,$$

$$L_2 = L_0 \cdot (3 + 1 - 2) / (3 + 1) = L_0 \cdot 1 / 2,$$

$$L_3 = L_0 \cdot (3 + 1 - 3) / (3 + 1) = L_0 \cdot 1 / 4.$$

Fig. 2.6.41. Proportional displacement of poles

The specified number n of poles for displacement can exceed the number of poles in a row. In this case, only existing poles will be displaced but the specified number n will be used in the calculation of each pole's offset.

To set up proportional displacement of poles, do the following.

1. In the **Condition** drop-down list, select the **Proportionally** option. Additional controls will become available on the Property bar (Fig. 2.6.42).

Fig. 2.6.42. Setup elements of proportional pole displacement

2. Set the direction of proportionally displaced pole counting.

The number of proportionally displaced poles is counted in a certain direction starting from the selected pole. The direction of counting in a row is set separately for each direction of the grid (U and V) using drop-down lists **U** and **V**. The following methods are available:

- ▼ **Before and after** — the number of poles to be moved is reckoned in each direction from the selected pole,
- ▼ **Before** — the number of poles to be moved is reckoned from the selected pole against the U/ V direction,
- ▼ **After** — the number of poles to be moved is reckoned from the selected pole in the U/V direction,
- ▼ **No displacement** — only selected pole is displaced; positions of other poles in the row will not be changed.

Select the desired item from each of the drop-down lists.

3. Enter the number of displaced poles in the **Before** and **After** fields for each grid direction separately (U and V). Displayed fields depend on the selected pole counting variant.

If several poles are selected, the preset number is counted in the row for each of them.

4. Move the selected poles manually. Proportional displacement of the defined number of poles will be performed automatically.

2.6.3.1.3. Displacement of poles with smoothening

Positions of grid poles of the edited face can also be changed with smoothening (Fig. 2.6.43).

Fig. 2.6.43. Examples of pole displacement with smoothening

The following types of smoothening are available (Fig. 2.6.44):

- ▼ **Smooth transition,**
- ▼ **Convex,**
- ▼ **Concave.**

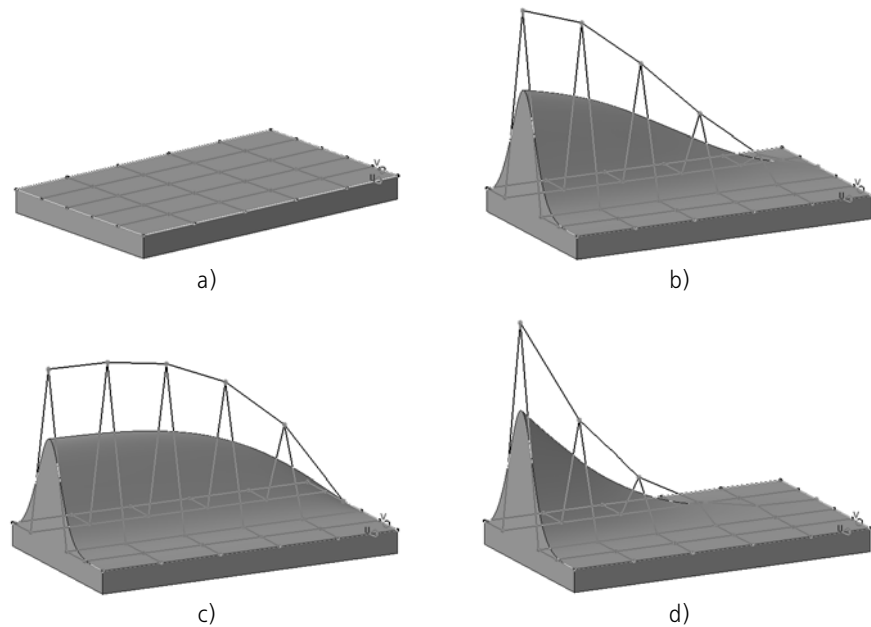

Fig. 2.6.44. Displacement of one row's poles with smoothing:
 a) initial face's state, b) **Smooth transition** type of smoothing,
 c) **Convex** type of smoothing, d) **Concave** type of smoothing

The selected poles are moved in the user-defined direction. In order to move poles, one of them should be displaced by the mouse. The remaining poles are automatically moved in the same direction.

The offset of each poles is calculated as follows.

Let P_0 is a pole which is moved by the mouse. Its offset L_0 is defined by the user.

P_i is a custom pole, one of the selected poles,

where i is the pole's number.

Offset L_i of the P_i pole is calculated automatically using the following formula:

$$L_i = k_i \cdot L_0,$$

where k_i is the smoothing factor for the P_i pole.

In order to calculate the smoothing factor, the following formulas are used:

$k_i = 1 - 3 \cdot x_i^2 + 2 \cdot x_i^3$ — spline function, smoothing of the **Smooth transition** type,

$k_i = 1 - x_i^n$ — exponential function, smoothing of the **Convex** type,

$k_i = (1 - x_i)^n$ — exponential function, smoothing of the **Concave** type,

where n is a natural number; value range of argument x_i $[0;1]$.

Therefore, the formula for calculation of L_i offset of the P_i pole, depending on the selected smoothing type, will look as follows:

$$L_i = (1 - 3 \cdot x_i^2 + 2 \cdot x_i^3) \cdot L_0, \text{ or}$$

$$L_i = (1 - x_i^n) \cdot L_0, \text{ or}$$

$$L_i = (1 - x_i)^n \cdot L_0.$$

The x_i argument is the distance between the pole for which the calculation is made and the straight line going in the direction of displacement through the P_0 pole.

Since the value range of the argument is $x_i [0;1]$, the distance to the outermost pole P_{max} is regarded as a unit segment $x_{max} = 1$. At the same time, the distances to all other poles (located closer) accept values between 0 and 1.

As a result of calculations for the outermost pole P_{max} , the displacement is equal to zero, i.e. this pole does not move. All other poles' displacement values are other than zero.

If, among the selected poles, there are several poles located at the same distance from the straight line going in the displacement direction through the P_0 pole, and this is a minor distance, non of the poles will be displaced.

An example of displacement with the **Smooth transition** smoothing type for 6 selected poles is presented in Fig. 2.6.45.

Fig. 2.6.45. Displacement of poles with smoothing of the **Smooth transition** type. The first of the selected poles P_0 is moved by the mouse. The last of the selected poles P_5 is the most distant from the straight line going in the direction of movement through the P_0 pole. The displacement of the P_5 pole is equal to zero.

Displacement with smoothing

1. Call the **Displacement with smoothing** command. The Property bar will display control elements for displacement parameters' settings (Fig. 2.6.46).

Fig. 2.6.46. Property bar during the displacement of poles with smoothing.

2. Specify poles that should be displaced (see Section 2.6.3.1.1 on p. 483).

If you need to move one pole (one row of poles), you do not have to specify a pole (row of poles). The displacement procedure is described in p. 7 of the current Section.

3. Select the required pole displacement direction option using the **Direction** drop-down list. The following methods are available:

- ▼ **Along the X axis,**
- ▼ **Along the Y axis,**
- ▼ **Along the Z axis,**
- ▼ **Parallel to an Object,**
- ▼ **Perpendicular to object,**
- ▼ **By normal.**

The description of the variants is given in Table 2.6.4 on p. 482.

Additional controls will become available on the Property bar after selection of the required option. The set of these controls and further actions depend on the selected variant.

4. Make additional displacement settings in accordance with the selected variant.
 - ▼ **Along the X axis/Along the Y axis/Along the Z axis** — no additional settings are required.
 - ▼ **Parallel to object/Perpendicular to object** — specify the guiding object in the model window. The name of the object is displayed in the **Guiding Object** field.
 - ▼ **By normal** — enable/disable the **From source** option.

If the option is enabled, the normal's position will be calculated with respect to the edited edge's source form; if the option is disabled — with respect to the current edge's form. The edge's source form is the form that the edge had at the moment of calling the **Spline form** command.

5. Select the type of smoothening by enabling one of the following switches of the **View** group:

- ▼ **Smooth transition,**
- ▼ **Convex,**
- ▼ **Concave.**

6. Enter the function's n degree value in the **Degree** field for the **Convex** or **Concave** variant. The field appears on the Property bar after selection of a variant.

7. Move the selected poles. To do this, move the cursor to one of them. When the symbol of a vertex appears next to the cursor, move the mouse to the required position keeping the left button clicked. After that, release the button. All selected poles (except for the pole which is outermost from the pole which is moved by the mouse) will be displaced in accordance with the preset smoothening type.

8. To finish the command, click the **Create object** button.

2.6.3.1.4. Rotation of poles

Positions of grid poles of the edited face can also be changed by rotation (Fig. 2.6.47).

Fig. 2.6.47. Rotation of poles:
a) face's original state, b) rotation result

Grid poles are rotated around the axis going through the rotation center in the defined direction. The rotation plane is perpendicular to the rotation axis and goes through the rotated pole.

An example of the pole displacement by rotation can be found in Fig. 2.6.48. The direction of the rotation axis coincides with the X axis of the current coordinate system; P_{start} and P_{end} — the initial and the final positions of the displaced pole.

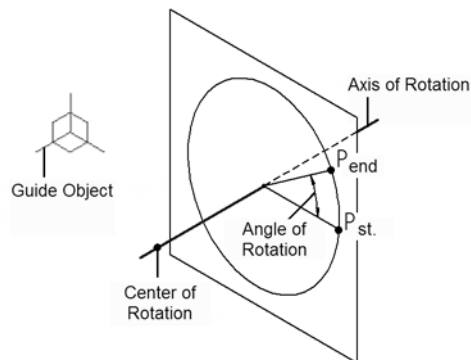

Fig. 2.6.48. Rotation of a pole

In order to move poles by rotation, perform the following operations.

1. Call the **Rotation** command. Round arrows will appear on the screen. The Property bar will display control elements for rotation parameters' settings (Fig. 2.6.49).

Fig. 2.6.49. Property bar in the process of poles rotation

2. Specify the poles that should be rotated (see Section 2.6.3.1.1 on p. 483).
3. Set the rotation axis direction by selecting one of the following variants from the **Direction** drop-down list:
 - ▼ **Along the X axis,**

- ▼ **Along the Y axis,**
- ▼ **Along the Z axis,**
- ▼ **Parallel to an Object,**
- ▼ **Perpendicular to an Object.**

The description of the variants is given in Table 2.6.4 on p. 482.

4. Specify the rotation center. To do so, select one of the following variants in the **Center** drop-down list:

- ▼ **None,**
- ▼ **LCS,**
- ▼ **Object's center,**
- ▼ **Center of selected,**
- ▼ **Point.**

The description of the variants is given in Table 2.6.5.

Tab. 2.6.5. Variants of the rotation center setting

Variant	Description
No	No center is specified. The rotation axis coincides with the guiding object or normal to the object (for direction Perpendicular to object).
LCS	The center coincides with the beginning of the current coordinate system (see Section 2.8.3.3 on p. 597).
Object's center	The center coincides with the mass center of the edge which is being edited. Coordinates of the mass center is calculated for the form the edge has at the moment of editing.
Center of selected	The center coincides with the mass center of the selected poles. To calculate mass center, the poles are presented by material points of similar weight.
Point	If this variant is selected, the Center's object switch is located on the Property bar (it is enabled by default). This switch makes it possible to specify a custom point object including one of the grid poles. The name of the selected object is displayed in a field next to the switch. The center will coincide with the object.

5. Enter the angle of revolution value into the **Angle** field. It can be both positive — rotation in the direction of the arrows — and negative with rotation in the opposite direction.

The selected grid poles will be moved in accordance with the preset rotation parameters.

6. If necessary, you can specify the manually selected objects again — grid poles or objects which define rotation parameters. For this purpose, enable the required switch (for example, the **Selection of poles** switch should be enabled for specification of a pole) and specify the object. To redefine all manually selected objects, click **Reselect** button of the Special Control Panel and make your choice again by enabling the respective switches.

7. To finish the command, click the **Create object** button.

2.6.3.1.5. Scaling

Positions of grid poles of the edited face can also be changed by scaling.

In order to displace a pole by scaling, the following methods are used (Fig. 2.6.50):

- ▼ even scaling,
- ▼ directional scaling,
- ▼ scaling in a plane.

Fig. 2.6.50. Pole scaling:
a) face's original state, b) even scaling,
c) scaling in a plane, d) axis scaling

The scaling is done as follows.

Even scaling — the pole is moved along a straight line connecting the scaling center with this pole until the distance between it and the scaling center increases k times, where k is the scaling factor.

An example of the pole displacement by even scaling can be found in Fig. 2.6.51.

This is a custom scaling center.

$P_{init.}$ and $P_{end.}$ — the initial and the final positions of the displaced pole.

$L_{init.}$ and $L_{end.}$ — distances between the initial and the final positions of the pole and the scaling center.

Fig. 2.6.51. Pole displacement with even scaling

Directional scaling — the pole is moved parallel to the straight line going through the scaling center in the defined direction until the distance between its projection on that straight line and the scaling center increases k times, where k is the scaling factor.

An example of the pole displacement by directional scaling can be found in Fig. 2.6.52.

The displacement direction coincides with the X axis of the current coordinate system, i.e. the pole is displaced parallel to the straight line going through the scaling center parallel to the X axis. This is a custom scaling center.

P_{init} . and P_{end} . — the initial and the final positions of the displaced pole.

P'_{init} . and P'_{end} . — projections of the initial and the final positions of the displaced pole on a straight line parallel to which the pole is being displaced.

L_{init} . and L_{end} . — distances between the initial and the final positions of the pole projections and the scaling center.

Fig. 2.6.52. Pole displacement during directional scaling, the X axis is the guiding object.

Scaling in a plane — the pole is moved parallel to the straight line connecting the scaling center and the pole's projection on the plane going through the scaling center parallel to the preset flat object. The displacement is performed until the distance between the pole's projection and the scaling center increases k times, where k is the scaling factor.

An example of the pole displacement by scaling in a plane can be found in Fig. 2.6.53.

The scaling plane is parallel to the XY plane of the current coordinate system and goes through the scaling center. This is a custom scaling center.

P_{init} . and P_{end} . — the initial and the final positions of the displaced pole.

$P'_{init.}$ and $P'_{end.}$ — projections of the initial and the final positions of the displaced pole on the scaling plane. The straight line, parallel to which the pole is moved, goes through the scaling center and the projection of the initial position of the $P'_{init.}$ pole.

$L_{init.}$ and $L_{end.}$ — distances between the initial and the final positions of the pole projections and the scaling center.

Fig. 2.6.53. Pole displacement during scaling within a plane, XY is the scaling plane.

In order to move poles by scaling, perform the following operations.

1. Call the **Scaling** command. The Property bar will display control elements for scaling parameters' settings (Fig. 2.6.54).

Fig. 2.6.54. Property bar during the displacement of poles by scaling

2. Specify the poles that should be displaced (see Section 2.6.3.1.1 on p. 483).
3. In the **Coefficient** field, enter the scaling coefficient. Selected poles will be displaced in accordance with the preset coefficient in the direction which is defined by the default scaling method and center.
4. Select the required scaling method from the **Method** drop-down list. The following s are available.
 - ▼ The **Even** variant for even scaling (selected by default).
 - ▼ For directional scaling:
 - ▼ **Along the X axis,**
 - ▼ **Along the Y axis,**
 - ▼ **Along the Z axis,**
 - ▼ **Parallel to an Object,**
 - ▼ **Perpendicular to an Object.**

The description of the variants is given in Table 2.6.4 on p. 482.

- ▼ For scaling within a plane:
 - ▼ **Within the XY plane,**
 - ▼ **Within the ZX plane,**
 - ▼ **Within the ZY plane,**
 - ▼ **In selected plane.**

If one of the first three variants is selected, its respective coordinate plane of the current coordinate system will be selected automatically (see Section 2.8.3.3 on p. 597).

The **In selected plane** variant makes it possible to specify a custom flat object (see Table 2.1.7 on p. 131) in the Design Tree or Model Window. There is also the Guiding object **switch (enabled by default) on the Property bar**. Specify the required object. The name of the object will be displayed in the field beside the switch.

5. Specify the scaling center. To do so, select one of the following variants in the **Center** drop-down list:
 - ▼ **LCS,**
 - ▼ **Object's center,**
 - ▼ **Center of selected,**
 - ▼ **Point.**

The description of the variants is given in Table 2.6.5 on p. 493.

After setting all scaling parameters, the selected poles will be positioned appropriately.

6. If necessary, you can specify the manually selected objects again — grid poles or objects which define scaling parameters. In order to specify the required object, activate the related switch (for example, the **Pole selection** switch should be enabled for pole specification. To redefine all manually selected objects, click **Reselect** button of the Special Control Panel and make your choice again by enabling the respective switches.
7. To finish scaling, click the **Create object** button.

2.6.3.1.6. Pole alignment

Positions of grid poles of the edited face can also be changed by alignment.

Two methods of grid poles alignment are available: **By direction** (Fig. 2.6.55) and **By flat object** (Fig. 2.6.56).

In the first case, the selected pole is moved to a straight line going through the alignment center in a predefined direction. The poles are moved perpendicular to the straight line.

In the second case, the selected pole is moved to the plane parallel to the predefined plane and going through the alignment center. The poles are moved perpendicular to the plane.

Fig. 2.6.55. Alignment of poles by direction:
a) face's original state, b) rotation result

Fig. 2.6.56. Alignment of poles by a flat object:
a) face's original state, b) rotation result

To move the pole by alignment (row of poles), complete the following steps.

1. Call the **Alignment** command. The Property bar will display control elements for alignment parameters' settings (Fig. 2.6.57).

Fig. 2.6.57. Property bar during the displacement of poles by alignment.

2. Specify the poles that should be displaced (see Section 2.6.3.1.1 on p. 483). The selected poles will be moved in accordance with the preset alignment parameters.
 3. Select the required alignment method from the **Method** drop-down list.
 4. Set direction or alignment plane.
- ▼ For alignment by direction, set the direction using the drop-down list with the same name. The following methods are available:
 - ▼ **Along the X axis,**
 - ▼ **Along the Y axis,**
 - ▼ **Along the Z axis,**
 - ▼ **Parallel to an Object,**

▼ **Perpendicular to an Object.**

The description of the variants is given in Table 2.6.4 on p. 482.

- ▼ For alignment by direction, set the direction using the drop-down list with the same name. The following methods are available:
 - ▼ **XY plane,**
 - ▼ **ZX plane,**
 - ▼ **ZY plane,**
 - ▼ **Selected plane.**

If one of the first three variants is selected, its respective coordinate plane of the current coordinate system will be selected automatically (see Section 2.8.3.3 on p. 597).

The **Selected plane** variant makes it possible to specify a custom flat object (see Table 2.1.7 on p. 131) in the Design Tree or Model Window. There is also the Guiding object **switch (enabled by default) on the Property bar**. Specify the required object. The name of the object will be displayed in the field beside the switch.

5. Specify the alignment center. To do so, select one of the following variants in the **Center** drop-down list:
 - ▼ **None,**
 - ▼ **LCS,**
 - ▼ **Object's center,**
 - ▼ **Center of selected,**
 - ▼ **Point.**

If the **No** variant is selected, no alignment is set. In the alignment process, straight line (plane) to which the poles are moved coincides with the selected straight-line (flat) object or normal to the object (for direction **Perpendicular to object**).

Description of other options for center setting is presented in Table 2.6.5 on p. 493.

After setting all alignment parameters, the selected poles will be positioned appropriately.

6. If necessary, you can specify the manually selected objects again — gird poles or objects which define alignment parameters. In order to specify the required object, activate the related switch (for example, the **Pole selection** switch should be enabled for pole specification. To redefine all manually selected objects, click **Reselect** button of the Special Control Panel and make your choice again by enabling the respective switches.

7. To finish alignment, click the **Create object** button.

2.6.3.2. Pole fixation

In the process of face editing, you may need some poles to remain static — fixed.

In order to fix poles, call the **Fix poles** command on the **Spline form** toolbar. The Property bar will display control elements for fixation settings (Fig. 2.6.58).

Fig. 2.6.58. Property bar in the process of poles fixation

The following fixation methods are available:

- ▼ Fixation of poles located on the grid borders (in its outermost rows),
- ▼ Custom pole fixation,
- ▼ Fixation of poles ensuring constant form and position of a face's edges.

You can fix poles using one or several methods at the same time. The procedure of pole fixation is described below.

To finish poles' fixation, click the **Create object** button.

Fixed poles are displayed on the screen as circles with a larger diameter.

2.6.3.2.1. Fixation of poles on the grid borders

The poles located on the grid borders are fixed using the group of switches **Borders along U** (for grid borders located in the U direction) and **Borders along V** (for grid borders located in the V direction) as is shown in Fig. 2.6.58.

By default, none of the grid borders is fixed, therefore, **No fixation** switches are enabled in the groups. Use the following switches to fix the required borders' poles:

- ▼ **Both grid borders**,
- ▼ **First grid border**,
- ▼ **Second grid border**.

In the face edit mode, you can fix all grid borders or cancel their fixation without calling the **Fix poles** command. To do so, the **Fix grid borders/Cancel fixation of grid borders** context menu command is used. Once this command has been called, switches for border fixation are automatically enabled in the **Fix poles** command:

- ▼ the **Fix grid borders** command — **Both grid borders** switches,
- ▼ the **Cancel fixation of grid borders** command — **No fixation** switches.

2.6.3.2.2. Custom fixation of poles

If you need to fix grid poles with free positions, enable the **Selection of poles** option and specify the required poles or pole rows by the mouse (for more information about pole selection, please refer to Section 2.6.3.1.1 on p. 483). Poles may be located in any grid row and on its border as well.

You can cancel fixation of a certain pole (pole row) by another click of the mouse on that pole (pole row). To cancel fixation of all poles, which had been fixed using this method, disable the **Selection of poles** option.

In the face edit mode, you can enable or disable selection of poles for fixation without calling the **Fix poles** command. For this purpose, the **Fix poles with Shift** context menu command is used. Calling this command makes it possible to select poles for fixation with the <Shift> key pressed; repeated calling cancels the fixation. In this case, the status of the **Pole selection** option in the **Fix poles** command will be changed automatically.

2.6.3.2.3. Fixation of poles ensuring constant form and positions of a face's edges

In the process of face editing, you may need to have the form and position of some or all of its edges unchanged. For this purpose, you can fix grid poles affecting the form and position of those edges.

For this kind of fixation, enable the **Selection of face's edges** option and specify all required edges by clicking on them one by one.

The selected edges are highlighted; all grid poles affecting the form and the position of these edges will be fixed automatically.

In order to cancel fixation of poles ensuring constant form and position of one of the selected edges, click this edge again. If you need to cancel fixation of poles for all selected edges, disable the **Selection of face's edges** option.

2.6.3.3. Changing spline surface parameters

In order to change the form of a face transformed into a spline surface (see Section 2.5.1.4 on p. 329), the grid formed by rows of control points (poles) is used. The grid poles are located in two directions: U and V.

By default, the grid has 6x6 dimensions (i.e. the number of grid poles along each direction is 6) and surface order equal to 4.

If a customized face is initially a spline surface, the grid dimensions and surface order are equal to the face's dimensions and order, respectively.

You can change the surface order and the number of its poles using the following **Spline form** toolbar commands:

▼ **Order**,

▼ **Grid**.

Detailed description of the commands usage can be found below.

2.6.3.3.1. Surface order

In order to change surface order, call the **Order** command.

Order along U and **Order along V** fields will appear in the Property bar. These fields make it possible to set the required order value for each of the grid directions (Fig. 2.6.59).

Fig. 2.6.59. Property bar after the grid order change

Enter values in these fields and or set them using the counter. The field's value can not be less than 3.

You can also change the number of grid poles. To do this, enable the **New grid** option. Additional controls will become available on the Property bar (Fig. 2.6.60).

Fig. 2.6.60. Setting the number of grid poles

Enter the required values in **Number of points in U** and **Number of points in V** fields and click the **Split again** button. The displayed grid will be rebuilt. The number of its poles will correspond to the set values.

In the same way, you can change the number of grid poles when working with the **Grid** command.

Note that the number of grid poles along the selected direction cannot be less than the surface's order set for this direction. Therefore, order increase results in automatic increase in the number of poles. Order reduction does not change the number of poles.

To finish the command, click the **Create object** button.

The **Interrupt command** makes it possible to cancel the changes made.

3.3.2. Grid dimensions

In order to make grid denser or wider, i.e. to change its dimensions, call the **Grid** command. Grid setup elements will appear on the Property bar (Fig.2.6.61).

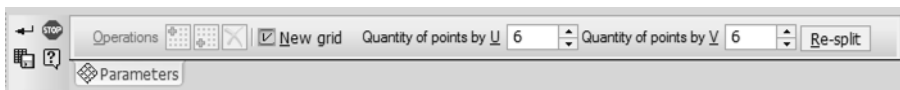

Fig. 2.6.61. Property bar after the grid dimensions change

You can change grid dimensions in two ways: by adding or deleting its rows; by setting the required number of grid poles.

In order to add a new row, specify one of the grid rows. In order to do so, click the grid's segment between two poles of the required row. In the **Operations** group, click the **Insert before the**

selected row or **Insert after the selected row** button. The new row will be positioned in the same direction as the selected row.

In order to delete a row, click it and then click the **Delete the selected row** of the **Operations** group.

You can also change the number of grid poles using the **New grid** option. Additional controls will become available on the Property bar after enabling the option.

Enter the required values in **Number of points in U** and **Number of points in V** fields and click the **Split again** button. The displayed grid will be rebuilt. The number of its poles will correspond to the set values.

In the same way, you can change the number of grid poles when working with the **Order** command.

If necessary, you can save grid poles' coordinates to the file of data. To do so, click the **Save to file** button on the Special Control Panel and specify the file name and the folder in the appearing dialog. By default the file shall be assigned the *txt* extension. For more information about the data file, see Chapter VI.

To complete grid setup, click the **Create object** button.

The **Interrupt command** button makes it possible to cancel the changes made.

2.6.3.4. Custom displacement of poles by the mouse

In the face editing mode, you can move one or several grid poles by the mouse and also fix poles that need not to be moved.

Pole fixation and displacement methods are described below.

If necessary, you can cancel earlier operations or redo them (see Section 1.4.1.6 on p. 79).

2.6.3.4.1. Techniques

In order to displace poles by the mouse, the following methods are used.

- +*
▼ To displace a pole, move the cursor to it. When the symbol of a vertex appears next to the cursor, move the mouse to the required position keeping the left button clicked. After that, release the button.
- +₂
▼ To displace all poles of one of the grid rows, move the cursor to this row's segment. When the symbol of a 3D curve appears next to the cursor, move the mouse to the required position keeping the left button clicked. After that, release the button.
- ▼
To displace several poles, click the mouse on them holding down the <Ctrl> key. Similar highlighting of a grid segment adds to the set of selected poles all poles in a row containing the segment. Another mouse click on the selected pole (pole row) with pressed <Ctrl> key deselects the pole (pole row).
- ▼
In order to displace all grid poles, highlight them using the **Select all poles** context menu command or <Ctrl>+<A> key combination. The **Cancel pole selection** context menu command deselects all grid poles. If you need to deselect only some of them, click the required poles (pole rows) holding down the <Ctrl> key.

if necessary, you can invert grid pole selection by calling the **Invert pole selection** context menu command. The highlighting will be removed from selected poles; all other poles will be highlighted.

When displacing poles, the form and/or the position of the face will change. If the new position of poles does not ensure correct changing of the face's form or position, the face remains in its initial state (refer to Section 2.6.3.6 on p. 507 for more details).

Note that you can displace unfixed grid poles only. Fixed poles cannot be displaced, even if they are highlighted.

To do so, the following context menu commands are used.

- ▼ **Fix borders** — makes it possible to fix all poles positioned on the grid's borders. To remove fixation, the **Cancel border fixation** command is used.
- ▼ **Pole fixation mode** — you can fix custom grid poles. Once the command has been called, poles are selected by clicking the mouse holding down the <Shift> key. Similar highlighting of a grid segment adds all poles in a row containing the segment to the set of fixed poles. If you need to cancel fixation of a pole (pole row), click it again keeping the <Shift> key pressed. In order to cancel fixation of all grid poles, call the **Pole fixation mode** command again.

You can fix poles or remove fixation using the **Fix poles** command of the toolbar (see Section 2.6.3.2 on p. 499).

By default, the selected poles are displaced within the screen plane. You can set another displacement direction using the **Offset direction** group of commands in the context menu. All available displacement variants can be found in Table 2.6.6.

Tab. 2.6.6. Context menu commands

Command	Description
Along the X axis Along the Y axis Along the Z axis	The commands make it possible to move selected poles along X, Y and Z axis of the current coordinate system (see Section 2.8.3.3 on p. 597).
Parallel to Object	You can use this command to displace selected poles parallel to a straight-line object (see Table 2.1.7 on p. 131) or cylinder, cone, toroid axis. Once the command has been called, specify the required object.
Perpendicular to Object	You can use this command to displace selected poles perpendicular to a flat object (see Table 2.1.7 on p. 131). Once the command has been called, specify the required object.
By Normal	You can use this command to displace selected poles along the normal to the edited face. It is impossible to move the poles behind the row's segment, if this variant is selected.

Tab. 2.6.6. Context menu commands

Command	Description
Along polygon	You can use this command to displace selected poles along U or V directions of the grid. Two offset variants are available for each direction. To the final , To the previous . In the first case, the pole is moved along the grid segment connecting this pole with the next pole in the selected direction (U or V); in the second case — in the opposite direction.
Within the screen plane	This command makes it possible to move selected poles within the screen's plane.

2.6.3.4.2. Peculiarities of setting the pole displacement direction

In case of a custom displacement of poles by the mouse, the displacement direction is set by context menu commands. These commands are related to Property bar controls that are used to set direction when working with **Linear displacement** and **Displacement with smoothening** commands.

For example, the following context menu command was called in the custom pole displacement mode: **Offset direction — Along polygon — Along U — To the previous**. Then, it was required to move poles by the **Linear displacement** toolbar command. After calling this command, the specified direction remained unchanged and its respective controls appear in the Property bar:

- ▼ in the **Direction** list — the **Along polygon** variant,
- ▼ in the **Type** group — **Along U** switch,
- ▼ in the **Method** group — **To the previous** switch.

If the offset direction changes while working with the **Linear displacement** or **Displacement with smoothening** command, this change will be saved after completing the command.

For example, when working with the **Displacement with smoothening** command, the **Parallel to object** variant was selected in the **Direction** list, and the guiding object is specified in the model window. Once working with the command has been finished, the specified direction remains unchanged, while the following command becomes automatically enabled in the context menu: **Offset direction — Parallel to object** (a tick appears next to the command's name). Besides that, the selected guiding object remains unchanged.

2.6.3.5. Construction of a spline form on a face's equidistant

Spline form can be constructed on a surface which is equidistant to the customized face, i.e. the resulting spline form will be a separate surface.

Using an equidistant surface makes it possible to prevent changing the initial face and its adjacent faces.

In order to create a spline form on equidistant surface, click the **Face's equidistant** button on the Special Control Panel after selecting a face for editing. A spline surface equidistant to the edited face will be created (for more information about the spline surface, refer to Section

2.5.1.4 on p. 329). It coincides with the edge, i.e. the distance between the edge and its equidistant is 0.

Note that the face selected for editing will be automatically transformed into a spline surface. After creation of the equidistant, the face will return to its initial state.

The **Face's equidistant** button can also be clicked before face selection. In this case, the equidistant surface will be created after face selection.

The equidistant surface can be edited using the same methods that are used for face editing. If the **Face's equidistant** button is enabled, all actions in the face editing mode are applied to its equidistant while the form and the position of the source face remain unchanged (Fig. 2.6.62).

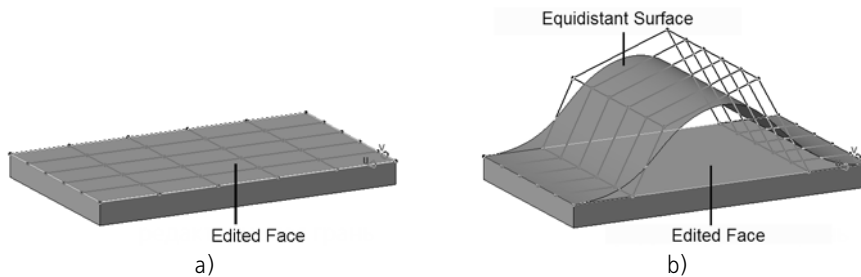

Fig. 2.6.62. Construction of a spline form on equidistant surface:
a) customized face,
b) equidistant surface and customized face

If a face had been customized prior to creation of an equidistant surface, the equidistant surface will take the form and the position of the face, which is being customized at the moment, while the customized face will return to its initial form and position.

You can cancel spline form creation on the equidistant of the edited face. To do so, disable the **Edge's equidistant** button. The equidistant surface will disappear while the customized face will be transformed into spline surface again. All operations performed in the editing mode will be applied to the edited face. The face will take the equidistant's form and position available at the moment of editing.

After editing the equidistant, its borders may differ from the source face's borders and be positioned in such a way that it will not be possible to join them with the adjacent faces of the part. In this case, when going back to editing the face, its form and position may differ from the equidistant's form and position at the moment. The face will remain in its initial state, as well as the grid's ghost.

Detailed description of face and face's equidistant customization peculiarities can be found in Section 2.6.3.6 on p. 507.

2.6.3.6. Face and face's equidistant customization peculiarities

- ▼ Note the following specifics when editing a face.
 - ▼ If the customized face is flat, its form will not change when moving grid poles within the face's plane.
 - ▼ In the process of face editing, the form and the position of its border may change. The form and the position of its adjacent face border may also change. These changes are possible only if the type of the adjacent face remain unchanged.

For example, the edited face and its adjacent face are both flat. In order to change the form of the edge between those faces, you should move the grid poles on it. You can move the poles in different directions. However, in this case, the edge's form will be changed in the plane of the face which is adjacent to the customized face. If poles' positions make it impossible to create an edge in this plane, the form of the customized edge will return to its initial state. And the grid poles will remain in the same positions.
- ▼ Customization of a face or its equidistant has the following peculiarities.
 - ▼ If the initial face contains more than 1000 edges, the **Spline form** command will be performed a bit slower.
 - ▼ If grid poles' positions were changed in the process of editing in such a way that the form of the face/face's equidistant cannot be built correctly, the face/face's equidistant will return to its initial form. And the grid poles will remain in the same positions.
 - ▼ Self-intersection is acceptable in the process of face/face's equidistant editing.
 - ▼ If you begin to edit a face's equidistant after editing the face, the face's current form and position will be applied to the equidistant. It is the same for the reverse situation (editing a face after editing its equidistant), except for cases when equidistant borders have the same position when joining the adjacent faces of the part is impossible. In this situation, the face will have the initial form and position.

The peculiarities of edge/edge's equidistant editing relate not only to the initial spline form creation, but also to its further editing.

2.7. Arrays

2.7.1. General information

2.7.1.1. Info on arrays

When working with a model, it may be necessary to create copies of objects (for example, operations or assembly components) which would be arranged in a certain way, forming a rectangular grid with set-up parameters or being symmetric about a plane.

To create ordered groups made of similar objects in the model, you can use array construction commands. KOMPAS-3D supports the capability of creating the arrays of the following types:

- ▼ by grid (see Chapter 2.7.3 on p. 537),
- ▼ by circular grid (see Chapter 2.7.4 on p. 543),
- ▼ along a curve (see Chapter 2.7.5 on p. 553),
- ▼ by Points (see Section 2.7.6 on p. 560),
- ▼ by table (see Chapter 2.7.7 on p. 565),
- ▼ mirror array (see Chapter 2.7.8 on p. 575),
- ▼ by sample (a kind of assembly components array; see Chapter 2.7.9 on p. 578).

Commands for constructing arrays are located in **Operations** menu, and the buttons to call them are on the **Arrays** panel (Fig.2.7.1).

Fig. 2.7.1. Geometric Objects Copy Commands

You can create arrays of the following objects:

- ▼ operations adding or deleting a body's material;
- ▼ bodies,
- ▼ surfaces,
- ▼ of curves,
- ▼ pixels,
- ▼ auxiliary planes,
- ▼ auxiliary axes,
- ▼ components.

You can copy previously created point groups, groups of isoparametric curves and arrays (except for arrays of bodies and surfaces and arrays with the table of modifiable variables).

The array of objects consists of **instances**. By default the first array instance is a **base instance**. It corresponds to the object being copied or to a group of objects, if there are several objects to be copied. Other array instances are copies of the base instance. You can change the array instances' position with respect to the base instance by assigning a certain number to it in the array.

If necessary, you can change the form and dimensions of instances by changing their variables' values (provided that the object being copied has variables). Such an option is available for all arrays except for mirror array and array by sample. Managing instance variables is described in detail in Section 2.7.2 on p. 519.

If bodies consisting of parts result from creation of the operations' array, the array's icon has a sign of several parts present— exclamation mark. For more information about bodies consisting of several parts, see Section 2.3.11 on p. 224.

Instances can be excluded from all arrays except for the array by sample (see Section 2.7.1.3.6 on p. 516).

All arrays, except for the operations' array, can be exploded to individual instances (see Section 2.7.1.3.7 on p. 517).

Creating an array by sample has some peculiarities. See Section 2.7.9 on p. 578 for details. Other arrays have common operation methods. See description of these methods in Section 2.7.1.3 on p. 512. See chapters 2.7.3–2.7.8 for more information on creation of these arrays.

2.7.1.1.1. Base point of an array's instance

The **base point of an instance** concept is used in the following arrays:

- ▼ on circular grid,
- ▼ by points,
- ▼ by table,
- ▼ along a curve.

The instance's location is defined with respect to the base point of the instance. At the same time, positions of the instances' base points are defined by type and parameters of the array. In the array on circular grid, the instances' base points will coincide with the grid nodes, in the arrays by points or by table – with the indicated points or with points obtained from a file, while in array along a curve, the instances' base points are positioned on the curve.

The base point of the base instance of an array is the **base point of the object to be copied** (see Section 2.1.1.4 on p. 104). Moreover, it is possible to select a point as a base instance's base point. Eventually, since all instances of the array are copies of the base array, their position with respect to base points will change in a similar way.

More information on building the above-mentioned arrays can be found in chapters 2.7.4 and 2.7.7.

If a rotation operation, a body created by the rotation operation, or a rotation surface is being copied, you can use projection of the **reference point of the object being copied** on the rotation axis of the object being copied instead of the point (see Section 2.7.1.3.3 on p. 514).

2.7.1.1.2. Displaying array's instances in the model's Design Tree

Array instances are displayed in the model's Design Tree as separate objects dependent on the array.

To expand the list of instances, click the mouse on the “plus” sign located at the left of the array icon in the Design Tree.

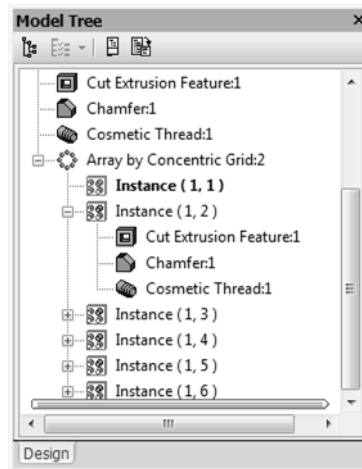

Fig. 2.7.2. Array on circular grid in the Design Tree

An array instance ID number is displayed in parentheses at the right of the instance icon.

- ▼ In case of a 2D linear array, an array instance ID consists of two numbers. The first one is an instance ID number along the first array axis, and the second one is the instance ID along the second axis (instance numbering starts with 1).
- ▼ For a circular array, an instance ID consists of two numbers. The first one is an instance ID number along the radial direction, the second one is the instance ID along the circumferential direction (instances numbering starts with 1).
- ▼ For copies placed along the curve, an instance's ID number is counted in the order the instances follow, starting from the source one.
- ▼ If copies are placed by points, the instance's number is the same as the number of the point which determines its position. The points are numbered in order of their selection.
- ▼ If copies are placed by coordinates (specified in a file or table), the instance's number is equal to serial number of the line in the file or table.

2.7.1.1.3. Point Variables

When you create an array in the Variables window of the model, the system automatically creates a section to store the variables of this array.

For the variables of each instance of the array, the system creates a dedicated subsection nested into the section of array variables. For example, the *Array by table:1* variables section can contain subsections *Instance (1)*, *Instance (2)* and so on.

Array variables include variables of sketch dimensions and operations. Such an option is available for all arrays except for mirror array and array by sample.

For an array by table, the instance variables also include the variables of instance dimension positions. These variables are automatically created when you set the positions of array instances. They correspond to the point coordinates read from the data file or can be specified in the table of array variables (see Section 2.7.7.2 on p. 568).

2.7.1.2. Application area of the operation's array instance

Each array's instance inherits the application area of the operation which it copies. For example, each copy of a rib is attached to the same body, to which the initial rib had been attached or each copy of a circular hole is cut from the same body or component, from which the initial hole had been cut and so on.

Changing of the ranges of applicability of operations' array instances is possible neither while creating, nor while editing the array.

When required, you can create an array of material removal operations (e.g. holes) to apply each copy of this array to the copy of the component. To do this, you can do the following:

- ▼ Create a component group.
- ▼ Build a hole going through the original component and add then add the component copies though which the copies of the hole must go through into the usage area.
- ▼ Create an array of holes.

2.7.1.3. General method of working with arrays

2.7.1.3.1. Choice of objects for copying

To choose objects, use the **Object selection** tab on the property tab (Fig. 2.7.3).

Fig. 2.7.3. **Object Selection** tab

The switches of the **Type** group enable the selection of the copied objects:

- ▼ **Auto definition by a setting;**

- ▼ **Operations;**

- ▼ **Bodies or surfaces;**

- ▼ **Curves, points, auxiliary geometry,**

- ▼ **Arbitrary** — this switch is available in the **Type** group only when an array by table is being created; for details on how to build an array with this switch enabled see Section 2.7.7.1 on p. 565.

- ▼ **Components**

By default, the **Auto definition by a setting** switch is enabled in the group. This means that the object type will be defined by the system automatically after setting the first object; the switch matching the type of the set object is enabled in the group. Specified objects becomes color highlighted, and its name will be displayed on the **List of objects** bar. To cancel object selection, re-select it.

If needed, select other objects of this type as objects for copying.

Note that the curves, points, auxiliary planes and axes can be bulk copied (i.e. can be located in the same array) while the bodies and surfaces cannot (i.e. an array can contain either bodies or surfaces).

During the creation of mirror copy of body or surface, the **List of Objects** panel is not active on the Properties bar.

To select objects of a certain type for copying, enable the switch of the respective type in the **Type** group. Then specify selected type object(s) in the Design Tree or in the model window.

Please note that when the edge, face or body vertex is selected in the model window, the **Operations** switch activates in the **Type** group, and when the edge, face or body vertex from the component contents is selected—the **Component** switch. If you need to select a body to copy, then activate **Bodies or Surfaces** switch before its selection.

You can also select objects for copying prior to calling the array creation command.

When copying the components, note that only the components of the first level (i.e. inserted directly into the current model) can be copied. Therefore, if an object is set in the Design Tree or model window, which is included in a component, the component will be selected for copying and its name will appear on the **List of objects** bar.

If a previously created array is used as an object for copying, it will be copied in its current condition. To copy an array, specify it in the Design Tree and specify any instance of the array in the model window. The name of the specified array will appear on the **List of objects** bar. Note that the type of objects of the array to be copied should be the same as the selected type of objects.

Copying body or surface arrays is impossible. Therefore, these arrays cannot be selected as source objects for an array.

A group of points of isoparametric curves can be copied both as a whole and partially. To copy the whole group of points or curves, specify this group in the Design Tree. The name of the specified group will appear on the **List of objects** bar. To copy individual points or curves, specify the required points or curves in the Design Tree or model window.

Selection of objects in the Design Tree or window is described in detail in Chapter 2.1.4.1 on p. 130.

To cancel selection of all the objects of the set type click **Re-select** button on the Advanced Control panel.

Before completion of the command the system “remembers” the objects specified for copying, so you can switch between function types without loss of their data.

Selection of copied object type is only available when creating an array. It is impossible to change the copied object type during array editing.

Peculiarities of selection objects for copying are described in Section 2.7.1.3.2.

2.7.1.3.2. Peculiarities of selection objects for copying

Chamfer and Fillet operations

Chamfer and **Fillet** operations can only be copied together with the object to which they had been applied. To copy a chamfer or a fillet, specify object creation operation in the Design Tree so that a chamfer or a fillet are built on the object's edges and then specify the chamfer or the fillet. In the model window, you can also specify edges, faces or vertices of the objects to be copied.

Rib

The rib array will be created correctly, if each copy of the rib adjoins the face of the body which the copied rib adjoins as well.

Shell and Slope operations

Shell and **Slope** operations cannot be copied using the array creation commands. Therefore, you should at first create copies of the required object, and then apply **Shell** and **Slope** operations to each copy.

You can copy an element without changing the slope of its faces (**Slope** command). To do this, enable the **Geometrical object** option when creating array of the element (see Section 2.7.1.3.5 on p. 515).

Add Thickness operation

If a new body is created using the **Add Thickness** operation, you can create a copy of this operation.

If the **Add Thickness** operation is applied to an existing body, it is impossible to copy it. Therefore, you should at first create copies of the required body, and then apply **Add Thickness** operation to each copy.

Cosmetic thread

If, upon copying a cosmetic thread, the feature whose face borders this thread is also being copied, the border for copied thread will be the copied face. Otherwise, the copied thread will be bound by the same face as the source one.

2.7.1.3.3. Location variants for the reference point of the object being copied for rotation bodies and surfaces

Instead of the **reference point of the object being copied** (see Section 2.1.1.4 on p. 104), you can use its projection on the rotation axis of the object being copied.

This option is available in arrays that use the **reference point of the base instance** (see Section 2.7.1.1.1 on p. 510) when copying the following objects:

- ▼ rotation operation,

- ▼ body created by the rotation operation,
- ▼ rotation surfaces.

You can enable/disable the use of the reference point's projection in the **Parameters** tab of the Property Bar using the **On rotation axis** option.

By default, reference point's projection is used for array creation, i.e. the **On rotation axis** option is enabled.

A change of the option's status is immediately reflected on the pattern ghost in the Model window.

2.7.1.3.4. Enabling/disabling display of array's ghost

When creating an array, you can enable or disable display of its ghost on the screen, as needed. Such an option is available for all arrays except for mirror array and array by sample.

To manage display of the ghost for the current (created or edited) array, button **Display ghost** is used in the Special Control Panel.

Upon changing the array settings, its ghost dynamically updates.

Using ghost makes array creation more convenient, since that supports a visual inspection of the creation result.

2.7.1.3.5. Geometric array

While creating an operation array, it is possible to expedite array creation and reconstruction. To do this, enable the **Geometric Array** option on the **Parameters** tab. When creating geometric array, only those faces and edges will be copied which result from the operation to be copied. No copying of operations and their parameters is done.

For the geometrical array to be constructed correctly, it is required that all its source objects were constructed either by adding, or by cutting material. You cannot mix objects of different types for copying.

The position of the copied surfaces with respect to existing ones which does not form a body, or the position of array's instances which does not result in an intersection of faces with each other, results in a construction error. In such cases, you should disable the **Geometrical Array** option.

Note the peculiarities when copying an object extruded **To surface**.

- ▼ When copying an object with the **Geometrical array** option disabled, each array instance is extruded to the same surface as the object to be copied. As a result, instances may differ in the height and shape of the “end face”.
- ▼ When copying an object with the **Geometrical array** option enabled, each instance is an exact copy of the source object.

If an array contains a table of variables (for details on a table, see Section 2.7.2.2 on p. 521), then when the **Geometrical array** option is enabled, you will see a message indicating that all variables will be removed from the table. Once you click **OK** all variables will be removed. For an array by table, all the variables except the coordinates of instance basic points are removed.

2.7.1.3.6. Removing and restoring individual instances

Sometimes, you may need to cancel creation of some instances or, vice versa, restore deleted instances. This can be done by doing the following when creating or editing an array.

1. Activate the **Deleted** tab on the Property Bar. Hot points and array instance numbers will be displayed on the screen.

2. In the **Mode** group, enable the **Delete/restore** switch¹.
 3. In the Model window, place the cursor on a handle of the array instance that needs to be deleted or restored. When the “Delete/Restore Instance” message appears next to the cursor, click the left mouse button.
- ▼ If an instance is deleted, its ghost will disappear, and its number will be displayed in the **Deleted** list on the property bar.
 - ▼ If an instance is restored, its ghost will appear again, and its number will be removed from the **Deleted** list.

You can restore deleted instance in a different way.

1. Highlight it in the **Deleted** list.
2. Click the **Restore** button above the list.

Only an entire instance can be excluded from an array. You cannot exclude individual copies of source objects from the contents of an instance.

There is another method of deleting array instances. Unlike the above described method, it becomes available only after the creation of an array. To modify the array in such a way, do the following.

1. Highlight instances in the Design Tree to be deleted and click the *<Delete>* button or call the **Delete** command from context menu.

A dialog will appear prompting you to specify whether all instances will be deleted (i.e. undoing the entire array creation operation) or only the selected instances will be deleted (Fig. 2.7.4).

2. Turn on **Instances** option.

Numbers of deleted array instances are displayed in the dialog (numbers of array instances are described in detail in Section 2.7.1.1.2 on p. 510).

3. Select the instance and click **OK** in the dialog.

The array will be rebuilt and displayed in the model window without the specified instances.

1. If you are going to copy bodies or surfaces, then the **Mode** group will not be available on the Properties panel, so you can simply skip this step. The same is for copying operations, when the **Geometrical array** option is enabled, and for copying custom selected objects using the **Array by table** command.

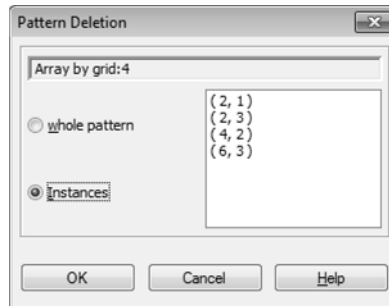

Fig. 2.7.4. Deleting array instances

You cannot delete array instances by sample.

2.7.1.3.7. Explosion of arrays

All arrays, except for operations array, can be exploded to individual instances.

You can do this by selecting the array to be exploded in the Design Tree and using the **Explode** command from the **Editor** menu.

In order to explode a single array, the **Explode** command may be called from the array's context menu in the Design Tree.

Upon calling the command, an explode dialog will appear. To confirm explosion, click **OK** in this dialog.

The rules of exploding arrays are as follows:

- ▼ the exploded array icon and its instance icons are removed from the Design Tree,
- ▼ array's objects are displayed in the Tree as individual model objects,
- ▼ objects which compose the array will change neither their parameters nor their positions in this array;
- ▼ objects corresponding to deleted instances of the exploded array will not be added to the model;
- ▼ if an original array for another (derived) array is exploded, the derived array is also exploded; exploding a derived array does not affect the original array.
- ▼ the components that comprised the array remain at positions they occupied in the array;

The types of objects generated by array explosion depend on the types of the array source objects (Table 2.7.1).

The output of exploding an array of custom selected objects by table (see Section 2.7.7.1 on p. 565) does not match the values in the table 2.7.1. All objects which compose the current array are converted into objects that exactly match the original ones.

Tab. 2.7.1. Results of Exploding an Array of Geometrical Objects

Source Object Type	Types of Objects Resulting from Array Explosion
Body	Body from Nowhere A body from nowhere cannot be edited.
Surface	Surface from nowhere A surface from nowhere cannot be edited.
Points and point groups	Point drawn by the By Coordinates (XYZ) method
3D Lines:	
Line	Segment by two points
Circular Arc	Circle Arc by Three Points.
Polyline	Polyline.
Spline By Vertices	Spline By Vertices.
Spline by Poles, Joining Curves	Spline by Poles.
Other curves	Curve from nowhere Curves from nowhere cannot be edited.
Auxiliary plane	Orthogonal plane (the position of a point through which the plane goes and the direction of the vector to which it is orthogonal are set automatically).
Auxiliary axis	An axis going through a vertex of an object (the position of a point through which the axis goes and the direction of the vector to which it is orthogonal are set automatically).

Note the following specifics of exploding an array of components. Once the array has been exploded, its components are positioned in the Model Tree so as if they were added to the assembly instead of array creation. This can be visualized by turning on model design sequence display in the Model Tree (methods of displaying objects in the Model Tree — see Sections 2.1.2.1 on p. 106 and 2.1.2.2 on p. 106).

For example, the assembly contained the following components added one by one: *Case*, *Gasket*, *Cap* (Fig. 2.7.5, a). Then, the *Gasket* array is created and the *Plug* component is added (Fig. 2.7.5, b). Then the array is exploded. The resulting sequence of components in the Model Tree will be as follows: *Case*, *Gasket* (1), *Cap*, *Gasket* (2), *Gasket* (3), *Plug* (Fig. 2.7.5, c).

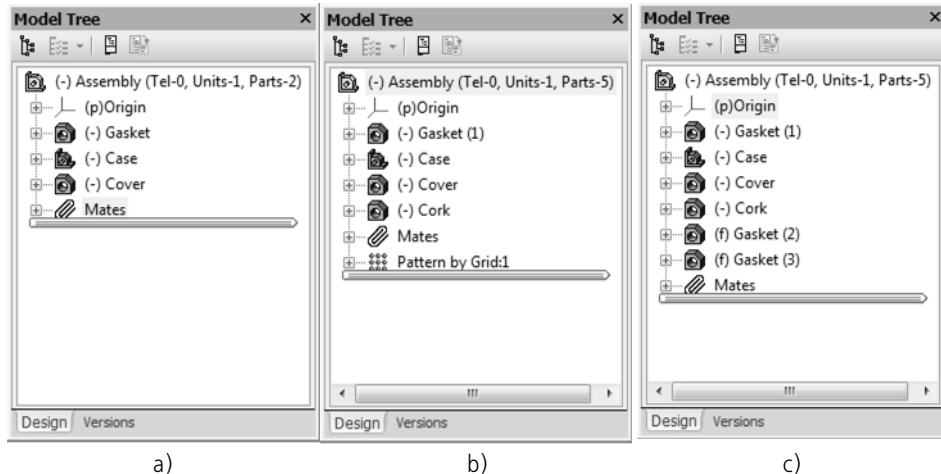

Fig. 2.7.5. Creating and destroying component arrays

If you've changed the values of the array instance variables (see Section 2.7.2 on p. 519), then after the explosion of such an array, the instance's shape and dimensions corresponding to the updated values will not change.

2.7.1.3.8. Peculiarities of array editing

When editing an array, it is impossible to change the type of the object being copied. The **Type** group of switches is not available on the **Choice of Objects** tab. This tab displays the icon of the object type selected for copying during array creation (Fig. 2.7.6 on p. 519).

Fig. 2.7.6. **Choice of objects** tab when editing an array of curves or points

2.7.2. Managing instances of variables

2.7.2.1. General Information

You can change the form and dimensions of instances by changing their variables' values. This option is available provided that the object being copied has variables affecting its form and dimensions.

Instances have the same variables as the object being copied. For example, variables of the extrusion operation are as follows: distance, tilt, and thickness of an item (for thin-walled items). These variables are also available in the instances of extrusion arrays.

By default, variables' values of the object being copied and instances are the same. You can create new values of variables for all array instances, except for the base one.

In Fig. 2.7.7, you can find an example of changing the dimensions of array instances along a curve. The extrusion operation is the copied object. New extrusion distance is set for each instance.

Fig. 2.7.7. Example of changing the dimensions of instances of the extrusion operation's array: new extrusion distance is set for each instance

Aside from the variables of an object being copied, the variables of the following objects used in the design can also be edited:

- ▼ sketches (if there are any dimensions with variables in them),
- ▼ auxiliary planes,
- ▼ curves (except splines and polylines),
- ▼ points.

For example, you can copy an extrusion item with a sketch built on a plane parallel to the XY plane and the extrusion depth is set according to the spacial position of the point. For copies of the array, you will be able to set new values ??of the variables that determine the dimensions of a sketch, the distance from its plane to the XY plane and the coordinates of the point to which you are extruding.

Afterwards, the variables of the copied objects include both these variables and the variables of objects used for building the copied object. Afterwards, the variables of an instance include a set of variables similar to those in the copied object.

You can manage the instance variables in two ways:

- ▼ using the table of variables (see Section 2.7.2.2),
- ▼ by editing the values of the instance dimensions (see Section 2.7.2.4 on p. 536).

You can also change the values of the instance variables after creating an array. To do this, you can use the Variables window (see Section 7.1.1.3 on p. 1571) or derived dimensions (see Section 2.9.2.8 on p. 648).

You **cannot** manage the instance variables in the following objects:

- ▼ in mirror arrays and arrays by sample,
- ▼ in other arrays:
 - ▼ when the bodies or surfaces are being copied,
 - ▼ when operations with the **Geometrical array** option enabled are being copied.

In all other cases, you **can** manage the instance variables. However, you cannot change variables of some types of objects. These include: sweep operation, operation by sections, operation of adding thickness, array, group of curves, group of points, and more. Copies of these objects in an array are always the same as in the original.

2.7.2.2. Table of modifiable variables

2.7.2.2.1. General Information

The **Table of modifiable variables** is a table saved in the model and containing variables of array instances.

The table of modifiable variables makes it possible to assign new values to variables of instances, thus modifying the instances' form and dimensions.

The table is formed by the user during array creation or editing. A table can be edited or deleted from the file in the future.

In order to change the form and dimensions of instances, create the table of modifiable variables so that it includes the required variables of instances. Then, assign new values to these variables.

New values of variables can be specified using two methods:

- ▼ by entering the new value in the respective cell of the table;
- ▼ by specifying the variables' increment values.

Array instances will be rebuilt in accordance to the new values of variables.

Creating the table of modifiable variables is described in Section 2.7.2.2.2 on p. 521, methods of assigning new values to variables are described in Section 2.7.2.2.4 on p. 526.

The table of modifiable variables saved in the model can be saved in the **data file** (see Appendix VI for more information about the data file). The table can also be read from the data file.

When creating an array by table, the table of modifiable variables can be used for setting instances' positions. Arrays by table are detailed in Chapter 2.7.7 on p. 565.

2.7.2.2.2. Creating, Editing and Deleting the Table of Modifiable Variables

Creation of the table of modifiable variables

To create the report on array, complete the following steps.

At Operation creation:

1. When creating or editing an array, click the **Table of modifiable variables** button on the Special Control Panel.

The following will be displayed:

- ▼ the **Table of modifiable variables** window with the table containing a column with instances' numbers;
- ▼ dimensions matching the variables of the object being copied (Fig. 2.7.8).

Fig. 2.7.8. Example of displaying dimensions corresponding to the extrusion operation variables.

If names of variables are not displayed on dimension lines, you can enable displaying them in the model window (see Section 2.9.2.2.3 on p. 637).

In case of the *array by table*, the table of modifiable variables contains coordinates of points that define positions of instances (see Section 2.7.7.2 on p. 568). You can enable/disable displaying coordinates in the table by clicking the **Define reference point coordinates** on the toolbar of the **Table of modifiable variables** window.

2. Create a set of variables of the object being copied, the values of which should be changed for instances.

Variables of some operations (*Hole from Library*, *Add Thickness*, *Cinematic Operation* and some others) cannot be added to the set.

For this purpose, specify the required dimensions of the object being copied in the model window. They are highlighted in color.

Columns corresponding to selected variables of the object being copied appear in the table. The first row contains the names of variables (headers of columns). In the second row, values of variables of the base instance are displayed. Each row of the table, starting from the third one contains the instance's number and empty cells.

An empty cell of the table of modifiable variables means that the variable in the cell has the same value as the value of the respective variable of the base instance. Therefore, the third and all other cells of the respective column will be empty immediately after adding the variable to the table.

Reselecting a dimension in the model window cancels its selection (the column related to the selected variable will be removed from the table).

3. Assign new values to variables. You can do this by the following methods:
 - ▼ by entering the new value of the variable in the respective cell of the table;
 - ▼ by specifying the variables' increment values.

Note that values of base instance's variables cannot be changed (the row with the values of the base instance is gray).

See section 2.7.2.2.4 on p. 526 for details about assigning new values to variables.

4. Click **OK** to close the **Table of modifiable variables** window.

The created table will be added to the file of the current model. Array instances will be rebuilt in accordance to the new values of variables.

See Section 2.7.2.2.3 on p. 524 for details about working with the table of modifiable variables.

When copying properties:

To create a table of modifiable variables, the component being copied must have external variables (for details about external variables, see Section 7.1.5.3 on p. 1593).

1. When creating or editing an array, click the **Table of modifiable variables** button on the Special Control Panel.

The **Table of modifiable variables** window with the table containing a column with instances' numbers will appear.

2. Create a set of variables of the object being copied, the values of which should be changed for instances. To do this use the **Read variables** or **Insert a variable** button in the **Table of modifiable variables** window. Description of button can be found in Section 2.7.2.2.3 on p. 524.
3. Perform steps 3 and 4 described above to create a table of modifiable variables when copying operations.

A table of modifiable variables is created automatically when you edit the dimensions of the array instances in the model window (see Section 2.7.2.4 on p. 536) or when you edit the variables matching these dimensions in the Variables window. The columns with modified variables are added into the table.

Editing the table of modifiable variables

Editing the table of modifiable variables is practically identical to its creating.

In order to begin editing the table, click the **Table of modifiable variables** button on the Special Control Panel.

Deletion of the table of modifiable variables

The table of modifiable variables may be deleted if it is no longer required. To do this, click the **Delete table** button on the Special Control Panel. As a result:

- ▼ modified values of variables for instances will be deleted from the file;
- ▼ instances' variables will accept the same values as the values of related variables of the base instance;
- ▼ instances will be rebuilt to become exact copies of the array's source object.

2.7.2.2.3. Working with the table of modified variables

The following options are available when working with the table.

Reading data from a previously created file

Click the **Read from file** button. Select the required file and press the **Open** button in the open file dialog. The table will be filled with data from the file (see Appendix VI for more information about the data file).

Saving the table to file

Click the **Save to file** button. The file save dialog will appear. Specify the file's location and name (by default, the file will have the *txt* extension) and click **Save**.

- ▼ If the table is saved during entry of variables' values, only numeric values of the variables will be saved in the data file. In case of array by table, coordinates of points defining instances positions can also be saved in the data file (see Section *Saving a table to data file* on p. 574 for more information about saving coordinates of points).
- ▼ If the table is saved during entry of variables' increment, only value steps will be saved in the data file.

When working with arrays by grid, by circular grid, along curve, or by points, **Read from file** and **Save to file** buttons will not be available if the table of modified variables is empty (has no columns with instances' variables).

When working with the array by table, these buttons are always available.

Adding variables of the copied object to the table

Click the **Read variables** button. Variables of the object being copied, that are not yet present in the table, will be added to it. Note that informative variables are not added to the table (see Section 7.1.1.2.1 on p. 1570 for more information about informative variables).

Adding a certain variable of the copied object to the table

Click the **Insert variable** button. The **Variables** dialog containing the list of all variables of the copied object appears on the screen. Specify the required variable and click the **OK** button. The selected variable will be added to the table.

Deletion of the selected column

Select the required column or any of its cells and click the **Delete column** button.

Changing the order of columns

Drag the column's header to the place you need (see Fig. 2.7.9).

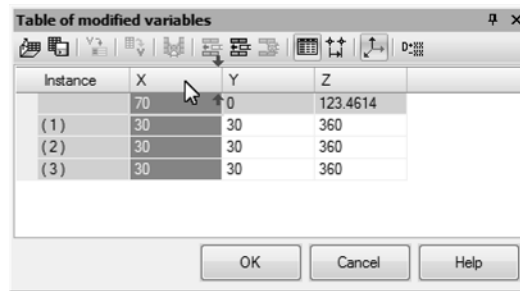

Fig. 2.7.9. Changing the order of columns in the Table of modified variables

Changing the number of rows in the table (for array by table)

Click the respective button:

- ▼ **Insert row above,**
- ▼ **Insert row below,**
- ▼ **Delete rows** (available only after selecting a row or a cell).

Changing the method of assigning values to variables for instances

- ▼ In order to use the method that makes it possible to enter arbitrary values in the table's cells, click the **Values of Variables** button.
- ▼ In order to use the method that makes it possible to specify the change value step, click the **Value step** button.

Details about assigning new values to variables for instances can be found in Section 2.7.2.2.4 on p. 526.

If a column contains values that do not form arithmetical progression (i.e. value step cannot be defined), entering the mode for setting the value step is only possible if data is deleted from this column. After clicking the **Value step** button, the system will request setting base values.

- ▼ Click **Yes** to delete the value in the column and begin setting the value step.
- ▼ Click **No** to retain the value in the column. In this case, the system will not enter the mode for value step setting.

Enabling/disabling display of coordinates in the table (for array by table)

Click the **Specify base point coordinates** button.

If an array of arbitrary objects is created (not the objects of a certain type), the **Specify base point coordinates** button will not be available in the toolbar.

Cancel changes in the table

Cancel changes in the table means deletion of new values from its cells. Empty table cell means that the value in it is the same as the base one.

▼ Cancel changes in cells

Click the required cell in the table and call the **Base Value** command from the context menu.

▼ Cancel changes in columns

Click the header of the required column and call the **Base Value** command from the context menu.

▼ Cancel all changes in the table

Call the **All base values** command from the context menu of the **Table of modified variables** window.

Enabling/disabling display of individual tolerances in the table

Click the **Display individual tolerances** button. More information about individual tolerances in the table can be found in Section 2.7.2.2.5 on p. 529.

2.7.2.2.4. Changing the value of an instance's variable

New values of instances' variables can be specified using two methods:

Method 1

Entry of the variable's value into the cell of the table of modifiable variables.

In order to use this method, click the **Values of Variables** button in the **Table of modifiable variables** window.

A table with the following structure will appear in the window (Fig. 2.7.10):

- ▼ The first column contains numbers of the array's instances.
- ▼ The first row contains the names of variables of the object being copied (headers of the table's columns).
- ▼ In the second row, values of variables of the base instance are displayed. Values in the row are not available for editing (the row is gray).
- ▼ Each row of the table, starting from the third one contains the instance's number and a set of variables modified by the user. An empty cell in the table means that the variable in the cell remains unchanged, i.e. its value is the same as the value of the respective variable of the base instance.

Instance	v9	v10	v14	v16
(1.1)	20	5	25	5°
(2.1)	25			6°
(3.1)				7°
(1.2)	30	3	30	6°
(2.2)				6°
(3.2)				7°
(1.3)	40	4	40	7°
(2.3)	40	4	60	7°
(3.3)				7°

Fig. 2.7.10. Example of the table of modifiable variables for entry of a new variable's value in the table's cell (array by grid)

To assign a value to a variable, you can enter a number or a mathematical expression into a cell in the table. Further steps are identical to those described in Section 7.1.3.3 on p. 1579.

Activate the required cell by double-clicking it, enter the new variable's value in it and click <Enter>. To move between cells, use arrow keys.

Individual tolerances may be assigned to dimensions of the sketch or operation of the object being copied (see Chapter 2.10.2 on p. 667). If the table contains variables of such dimensions, you can enable displaying tolerances in the table. For this purpose, the **Display individual tolerances** button is used (see Fig. 2.7.10 on p. 527). When working in the table, you can change tolerances for dimensions of the sketch or operation (see Section 2.7.2.2.5 on p. 529).

Method 2

Specifying the variables' increment value.

In order to use this method, click the **Increment value** button in the **Table of modifiable variables** window.

A table with the following structure will appear in the window (Fig. 2.7.11):

- ▼ The first row contains the names of variables of the base instance (headers of the table's columns).
- ▼ In the second row, values of variables of the base instance are displayed. Values in the row cannot be edited.
- ▼ The third row is used for setting the increment value for variables.

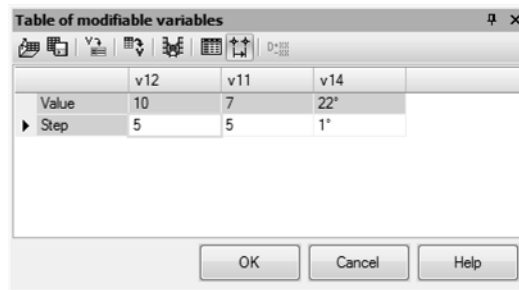

Fig. 2.7.11. Example of the table of modifiable variables for specifying the variables' increment value

In the third row of the table, activate the required cell by double-clicking it, enter the increment value in it and click <Enter>. The step value can be both positive and negative. To move between cells, use arrow keys.

If necessary, you can view the new values of variables. For this purpose, click the **Values of Variables** button in the **Table of modifiable variables** window. The table with the variables' values will be displayed in the window. The column of the variable, for which increment value was assigned, will contain its new values.

Note that the value of the variable that will be assigned to a certain instance depends on its **number and array type**.

- ▼ In arrays by parallelogram or circular grid, values of variables for instances are changed in accordance with the diagrams shown in Fig. 2.7.12 and 2.7.13.

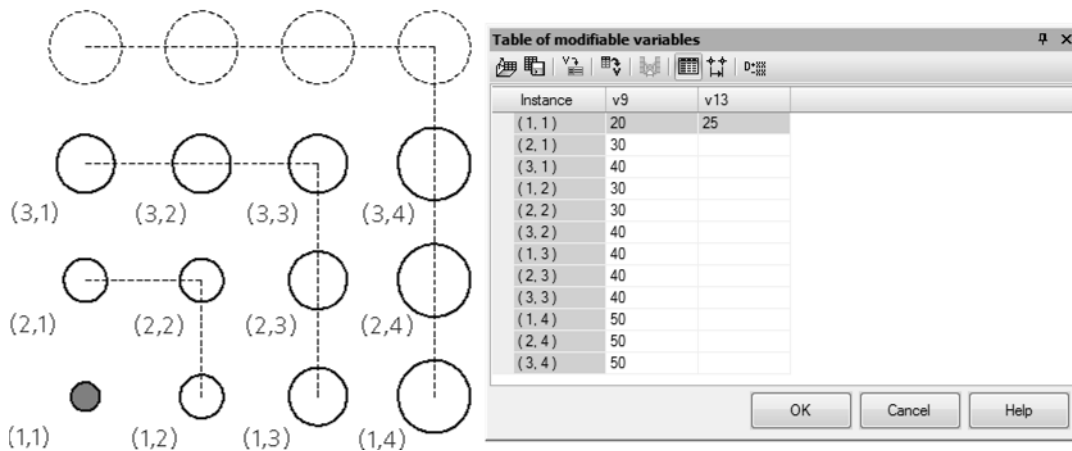

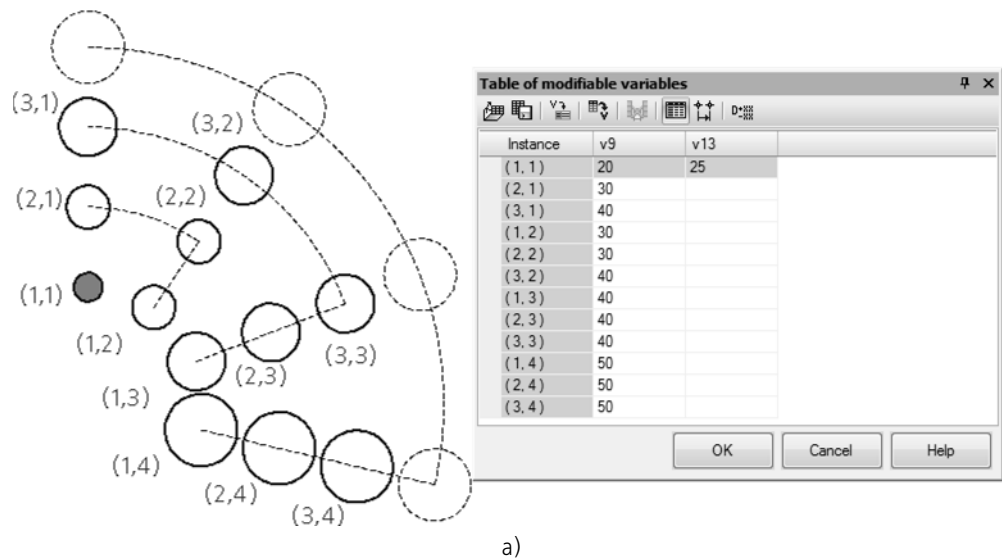

Fig. 2.7.12. The diagram of changing variables' values with a specified increment for instances of an array by parallelogram grid

a)

Fig. 2.7.13. The diagram of changing variables' values with a specified increment for instances of an array by circular grid

- ▼ In arrays by curve, by points, and by table, values of variables for instances are incremented along the instances' numbers (Fig. 2.7.14).

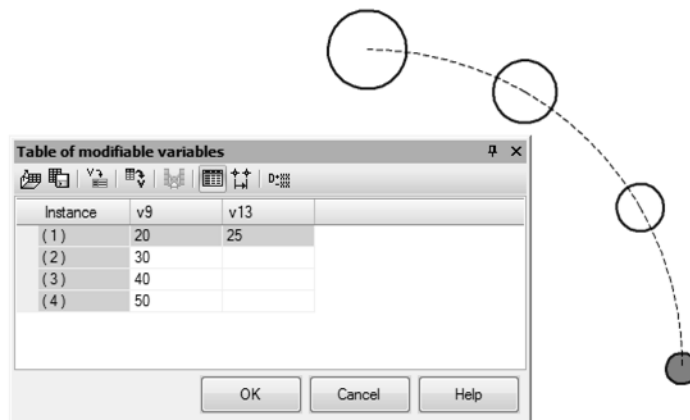

Fig. 2.7.14. The diagram of changing variables' values with a specified increment by the order of instances' numbering (creation of an array by a curve)

Thus, in the first case, some instances have similar values of the variable (Fig. 2.7.12 and 2.7.13); in the second case, all variables' values will be different (Fig. 2.7.14).

2.7.2.2.5. Individual tolerances in the table of modifiable variables

You can assign tolerances (general and individual, see Chapter 2.10.2 on p. 667) to values of instances' parameters (guiding dimensions of the sketch and operation's parameters). If indi-

vidual tolerances are assigned, you can enable displaying them in the table. For this purpose, the **Display individual tolerances** button is used (see Fig. 2.7.15 on p. 530).

You can view individual tolerances in the table of modifiable variables, if new values of instances' parameters are set using a method supporting manual entry of arbitrary values in the table's cells (**Method 1**, see 2.7.2.2.4 on p. 526).

If the **Display individual tolerances** button is enabled, the following data is displayed in the table's cells:

- ▼ The cells of the second table's row contain the base instance's data;
 - ▼ values of the base instance's parameters,
 - ▼ assigned tolerance – class of accuracy and maximum deviations or limit values of the base instance parameters.
- ▼ In other rows of the table starting from the third one, the following information is displayed:
 - ▼ a set of modified values of instances' parameters,
 - ▼ tolerances for the values of instances' parameters.

Instance	v12	v113	v14
(1. 1)	59h14(-0,74)	27	14'(+1';-1')
(2. 1)	70h8(-0,046)		15'(+1';-1')
(3. 1)		90h14(-0,87)	16'(+1';-1')
(4. 1)			17'(+1';-1')

Fig. 2.7.15. Displaying individual tolerances in the table of modifiable variables

Note the following specifics of object property displaying in a drawing.

- ▼ An empty cell of the table means that the value and tolerance of the instance's parameter in this cell are the same as the value and tolerance of the respective parameter of the base instance.
- ▼ A cell contains only the value of the parameter — this means that either general tolerance or no tolerance is assigned to the instance parameter in this cell.
- ▼ A cell contains both the value of the parameter and the specified tolerance — this means that the value and/or tolerance of the instance in this cell differ from the value and/or tolerance of the corresponding parameter of the base instance.

If the **Display individual tolerances** button is enabled, cells of the table of modifiable variables are not available for manual entry.

In the table of modifiable variables, you can assign or change tolerances for instances' parameter values. For this purpose, the **Value and tolerance** dialog should be used.

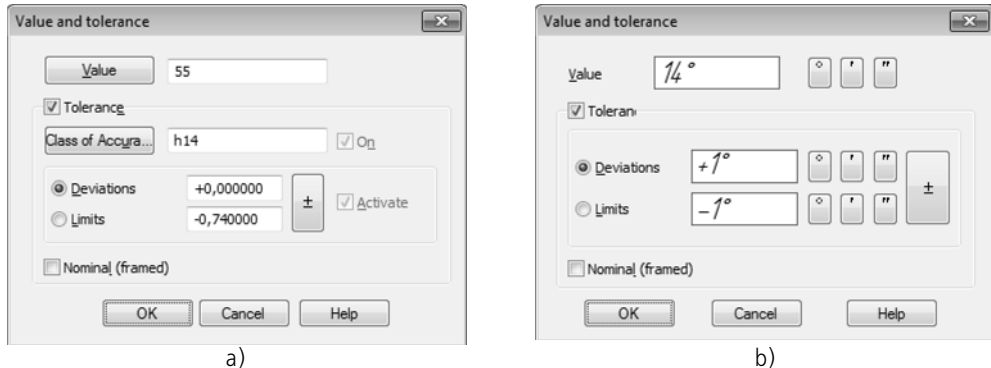

Fig. 2.7.16. The **Value and tolerance** dialog
a) for a linear value, b) for an angular value

The dialog is called using the following methods:

- ▼ by the **Assign tolerance** command of the table cell's context menu.
- ▼ if **Display individual tolerance** button is enabled, by clicking the ellipses button in the right part of the cell, or by double-clicking the cell.

Controls of the **Tolerance** group are described in Table 3.3.5 on p. 982. Assigning tolerance procedure is the same as the procedure described in Section 2.10.2.2 on p. 669.

The dialog also makes it possible to assign a new value of the instance's parameter. For this purpose, the **Value** field and the respective button (the button is present in the dialog for instances' parameters whose values are expressed in linear values) are used. You can input a new value using the keyboard. For an instance expressed in linear values, you can also select a value from the user menu. To do so, click **Value**. The user menu will appear on the screen. By default, it contains normal linear dimensions by GOST 6636-69.

After performing all necessary operations in the dialog, close it by clicking the **OK** button.

When the value of the variable is a mathematical expression, you cannot change the parameter value in the tolerance configuration dialog. The **Value** field and a same-name button are not displayed on the dialog.

You cannot change the data of the base instance (the table row containing the values of the base instance is grayed out).

2.7.2.3. Report on array with the table of modifiable variables

If an array contains the table of modifiable variables (see Section 2.7.2 on p. 519), you can create a report on the array. The report is a table with information from the table of modifiable variables (a set of variables and their values, point coordinates). The array report's table can be placed in a graphical or text document. You can edit data in the table, change its header, location and so on.

The report on the array can be linked associatively to the source of data (a model) or not linked to it. The associative link is formed during creation of the report. The procedure of creating the report on array can be found in Section 2.7.2.3.1 on p. 532.

If the report on array is associatively linked to the source of data, you can update data in the report, open the source document and use commands for editing that are available for associative reports (see Section 5.2.3.8 on p. 1433). For a report on array which is not linked to a data source, these options are not available.

You can work with the table of the report on array in the same way as when working with the table of variants (see Section 2.13.4.3 on p. 776).

Parameters of the table of the report on array are arranged and set up during its creation or editing (see Sections 2.7.2.3.2 on p. 533 and 2.7.2.3.4 on p. 535). Text of a table located in a graphical or text document is displayed in accordance with the setup of text parameters of the report's table applied to that document (see Sections 9.2.4.7 on p. 1754 and 9.2.6.23 on p. 1835).

2.7.2.3.1. Creation of the report on array with the table of modifiable variables

In order to create the report on array with the table of modifiable variables, do the following:

1. Open a model containing the array with the table of modifiable variables (see Section 2.7.2.2 on p. 521 for details about the table).
2. Call the **Create report on array with the table of modifiable variables** from the **Service – Reports** menu or using the respective button on the **Reports** bar.

Elements for creation of the report will appear in the Property Bar (Fig. 2.7.17).

Fig. 2.7.17. Property Bar during creation of the report on array

3. Select the required array in the Design Tree or in the model window.

It is impossible to select an array without the table of modifiable variables.

The selected array will be highlighted. The name of the selected array is displayed in the field beside the **Array** switch.

After selection of an array, the setup dialog for the table of the report on array appears on the screen (see Fig. 2.7.18 on p. 534).

In order to reselect an array for creating the report, close the setup dialog of the report table and select the required array. Once the array is selected, the setup dialog for the table of the report will appear on the screen again.

The array, for which the report should be created, can be selected before calling the command. In this case, the setup dialog for the table of the report should be called by clicking the **Setup...** button on the Property Bar.

4. Set up parameters of the table of the report on array (see Section 2.7.2.3.2 on p. 533).
5. Using the **Associative report** option, enable/disable creation of the associative link between the report being created and the source document (model).
 - ▼ If the option is enabled, the created report will be linked associatively to the source document. Changes in the source document (in the table of modifiable variables) will be transferred to the report.
 - ▼ If the option is disabled, then the report is created without the associative link to the source document. In this case, changes in the source document will not be transferred to the created report.

The **Associative report** option is available on the Property Bar during creation of the report on array as long as the source document is saved to a file on the disk. During the report editing, the option is present on the Property Bar.

The associative report on array should be placed in a graphical document. If placed in a text document, the associative link between the report and the source document will not be created.

6. You can enable automatic assignment of numbers to report tables. To do this, choose the numbering group from the **Numbering** drop-down list (for details about numbering, see 3.9.1 on p. 1277).
7. Set up the table contents for the report on array (see Section 2.7.2.3.4 on p. 535).

8. In order to finish creating the report, click the **Create Object** button.

This will display the dialog to select a document or the standard dialog to open files. Open the required graphical or text file.

 - ▼ Locate the ghost of the report table in the graphical document. For this purpose, specify the location of the table's snap point by the cursor or by entering coordinates on the Property Bar and click the left mouse button to fix the table. If necessary, you can modify it (see Section 4.2.2.1.3 on p. 1364).
 - ▼ In a text document, the report table is located automatically.

2.7.2.3.2. Setup of the table of the report on array

Setup of the table of the report on array is performed in the **Parameters of the table of the report on array** dialog (Fig. 2.7.18).

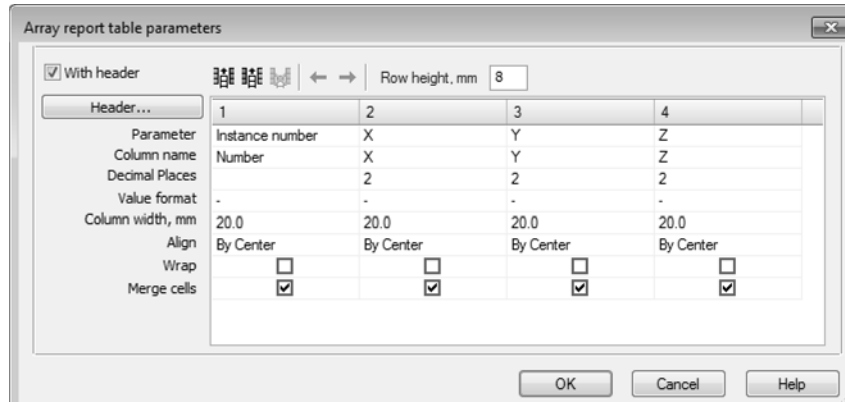

Fig. 2.7.18. Setup dialog for the table of the report on array

The dialog is called during creation or editing of the table of the report on array:

- ▼ automatically after selection of an array;
- ▼ or by clicking the **Setup...** button on the **Report on array** tab of the Property bar.

By default, the dialog shows the columns matching the columns in the table of modifiable variables of the selected array, as well as a column containing the numbering of the instances. You can remove or restore any columns in the report.

Pay attention to the following feature of the table of modifiable variables in the array by table. In this array, the table of modifiable variables always contain the columns of coordinates of the array instances, but you can show or hide them as required. The same columns in the report's table can be either included or excluded depending on whether they are currently enabled in the array.

In the **Parameters of the table in the report by array** dialog, you can do the following.

- ▼ Selection of the table display option – with header or without it. For this purpose, the **With header** option is used.
- ▼ Adding, deletion, and moving of the table's columns; controls are the same as those used for the report table setup (see Table 5.2.2 on p. 1408).
- ▼ Setup of the table's columns display parameters and data contained in them (see Section 2.7.2.3.3 on p. 535).
- ▼ Setting the table's row height. For this purpose, the **Row height, mm** field is used. The value is manually entered in this field.
- ▼ Setup of the table's heading. The table's heading is set up in the same way as the heading of the table of variants (see Section 5.2.2.2.4 on p. 1411).

In order to finish the table setup, click the **OK** button. To leave the dialog without making changes to the settings, click the **Cancel** button.

Columns of the table of the report on array depend on the table's settings. In order to change the set of columns of the table of the report on array, it is necessary to change its settings. Changing the set of columns of the modifiable variables table (in the source document) is not transferred to the associative report on array.

2.7.2.3.3. Display setup for columns of the table of the report on array

The following parameters can be set up for table columns of the report on array:

- ▼ **Column name, Decimal places, Column width, mm, Alignment, Wrap**; the setup is the same as for the report style parameters described in Table 5.2.3 on p. 1410,
- ▼ **Parameter, Value format, Merge cells**; the setup is described in Table 2.7.2.

Tab. 2.7.2. Display setup parameters for columns of the table of the report on array

Element	Description
Parameter	This field* contains the name of the array instances' parameter (for example, coordinates of points that define instances' positions, names of variables). Choose the parameter's name from the list. The list of instances' parameters corresponds to columns of the table of modifiable variables in the selected array.
Value format	This field* makes it possible to choose the variant of displaying the value of the instance's parameter in the table: <ul style="list-style-type: none"> ▼ <i>Value</i>, ▼ <i>Value + tolerance</i>, ▼ <i>Tolerance</i>.
Merge cells	This option makes it possible to merge adjacent cells in a column of the table, if the cells' contents is identical, i.e. if the displayed value is the same for these adjacent cells.

* The control allows to select an option from the drop-down list. After you click a cell, in its right corner there appears a button with a triangle. Press the button to display the list for selecting a parameter option.

2.7.2.3.4. Array report table contents

Information about parameters of the array's instances can be presented in more than one table. The setting that is used to select the method of positioning tables on a sheet is made on the **Contents** tab of the Properties Bar (Fig. 2.7.19).

Fig. 2.7.19. **Contents** tab of the Properties Bar

In order to create several tables and adjust their positions on the sheet, perform the following actions.

1. You can have several tables by enabling the **Split table** option.
2. In the **Number of rows** in table, specify the maximum number of rows in each table. Display parameters are the same for all tables.
3. To specify the order of tables' positioning on the sheet, choose the required direction of positioning from the **Contents** drop-down list.
- ▼ The **To the right, then downwards** option positions tables in horizontal rows. The number of tables in a row is specified in the **To the right, not more than** field.
- ▼ The **Downwards, then to the right** option makes it possible to position tables in vertical rows. The number of tables in a row is specified in the **Downwards, not more than** field.
4. Enter the value of distance between tables in the **Gap, mm** field. You can enter the required value of the distance manually or select it from the drop-down list.

2.7.2.4. Dimensions of the array instances

When working with all types of arrays, except the mirror arrays and arrays by sample, you can adjust the shape and dimensions of the instances by changing the **dimensions of sketches and operations** of these instances.

The dimensions of the sketches and instances correspond to the same dimensions of the object being copied.

To display the dimensions of the sketches and operations for a certain instance in the model window, perform the following.

1. When creating or editing an array, expand the **Instances** tab on the Properties panel.
2. In the **Mode** group, enable the **Edit dimensions** switch.
3. Choose the instance you want on the **List of instances** panel.
4. On the **List of objects** panel, choose the object (a sketch or an operation) which dimensions you want to display. The dimensions of the object will appear in the model window.

Dimensions of sketches and operations are not displayed in the Design Tree.

You can edit values of the following dimensions: This can modify the geometry of the array instance. The appearance and methods for the dimensions of the sketches and operations of the array instances are similar to those described in Section 2.9.2.2 on p. 632.

When a dimension is changed, its variable is added to the table of modifiable variables of the array (if this table does not exist, the system will create it).

For arrays by table, you can also adjust the position of the instances by changing the values of **instance position dimensions**.

These dimensions are created when you set the coordinates of points which define the positions of the array instance, and they match these coordinates. The variables of the position dimensions are added into the Variables window.

By default, the dimensions of the instance positions are not shown in the Model window. To display the dimensions of the position for a certain instance, choose it on the **List of instances** panel (see step 3 described above).

To change the position of an instance, edit the values of dimensions. You can work with position dimensions similar to the dimensions of sketches and operations.

If the coordinates of points which define the positions of the array instance are taken from a file, then the values of the position dimensions cannot be edited. In this case, the dimensions of positions are not displayed.

The tolerances for dimensions of the sketches and operations of array instances are the same as for the corresponding dimensions of an object being copied. By default, the dimensions of positions are assigned general tolerances.

When editing a value of a dimension, you can assign it another tolerance or even remove the tolerance at all.

You can also adjust the geometry and positions of the array instances when required using the derived dimensions 2.9.2.8 on p. 648. These dimensions can be created for the entire array, for an array instance, or for objects included into an array instance.

The dimensions are created after creation of the array.

2.7.3. By grid array

You can create an array of objects by positioning them in parallelogram grid nodes, for example, as is shown on the Fig. 2.7.20.

Fig. 2.7.20. Example of array along grid

The grid formation scheme is described in Section 2.7.3.1, array construction procedure — in section 2.7.3.2.

2.7.3.1. Formation scheme of parallelogram grid

Parallelogram grid is characterized by the direction of its generating vectors and the angle between them (Fig. 2.7.21). Any point of copied objects may be the origin of the grid coordinates.

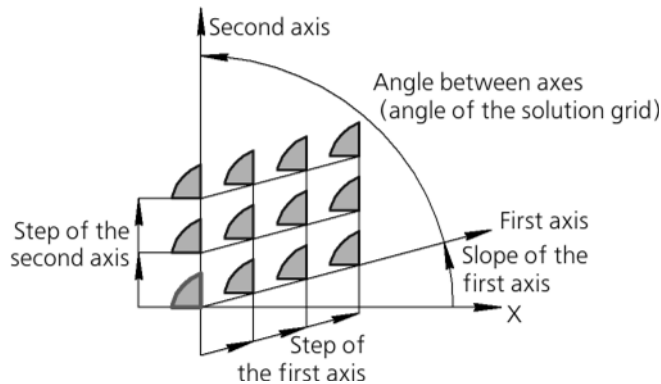

Fig. 2.7.21. Formation scheme of parallelogram grid

Array instances are displayed as ghosts and positioned in space in accordance with the preset parameters of the grid. A ghost allows a visual control over parameter accuracy.

2.7.3.2. The Procedure for Construction of a Array by Grid

To create an array by grid, complete the following steps.

1. Call the **Array by Grid** command.

Once the command has been called, the property bar will contain the **Choice of objects** tab (see Fig. 2.7.3 on p. 512).

2. Specify the **copied object**: operations or bodies or surfaces or curves, points, auxiliary planes and axes, or components.

For details about copied object selection, see Section 2.7.1.3.1 on p. 512.

Names of the selected objects are displayed on the **List of objects** bar; the array's ghost will appear on the screen.

You can also select objects for copying prior to calling the array creation command.

Once objects for copying have been selected, **Parameters**, **Deleted**, **Properties** tabs will appear on the property bar.

3. Go to the **Parameters** tab.
 - 3.1. Using the tab's control elements, set **grid parameters** for the first axis (see Section 2.7.3.3 on p. 539), then for the second axis (see Section 2.7.3.4.1 on p. 540).
To set the array grid parameters, you can use hot points (see Section 2.1.4.2.2 on p. 138 for description of hot points).

You can arrange the array grid parameters using the hot points without switching to the **Parameters** tab.

All the changes will be reflected in the array ghost.

4. If required, you can also:
 - ▼ Changing array instances' positions with respect to the **base instance**— the instance which corresponds to the objects to be copied (see Section 2.7.3.5 on p. 541).
 - ▼ Selection of **copy positioning method** inside the grid (see Section 2.7.3.6 on p. 542).
 - ▼ Creating a **geometric array** with operations to be copied (see Section 2.7.1.3.5 on p. 515).
 - ▼ Deleting and restoring array instances. Enable the **Instances** tab of the Properties Bar. More details about deleting or restoring instances can be found in Section 2.7.1.3.6 on p. 516.
 - ▼ Managing form and dimensions of instances by changing their variables' values (see Section 2.7.2 on p. 519).
 - ▼ Changing of array name and properties of surface of instances. Enable the **Properties** tab of the Property Bar.

5. Confirm array creation

Created array appears in the model window, while the icon attributable to its type is displayed in the Design Tree.

2.7.3.3. Grid parameters along the first axis

2.7.3.3.1. First Axis Direction

When copying an operation, direction of the first grid axis by default coincides with the *X* axis of the sketch for this operation.

If you are copying extrusion or rotation operations that use other objects – not a sketch (for example, a face) – as a section, the direction of the first grid axis by default will coincide with *X* axis of the absolute coordinate system.

If several operations are selected for copying, the direction of the first grid axis is set by *X* axis of the sketch or by the *X* axis of the absolute coordinate system of the first specified operation.

When copying other types of objects, the direction of the first default grid axis coincides with *X* axis of the current coordinate system (see Section 2.8.3.3 on p. 597 for details on selection of the current coordinate system).

The name of the guide object for the first axis will appear in the **Axis 1** field on Property bar.

You can change the first axis direction as follows:

1. Set angle between the first axis and *X* axis of the current coordinate system in *XY* plane or *X* axis in the operation's sketch plane. To do this, enter the value of the first grid axis slope in the **Slope** field.
2. Select the guide object in the window or in the Design Tree. You can use any rectangular or flat object as a guide, as well as a cylindric or conical surface. Straight and flat objects are listed in Table 2.1.7 on p. 131.

Direction, defined by a straight object — a line parallel to the object.

Direction, defined by a plane object — a line perpendicular to the object.

The direction defined by a cylindrical or conical surface is a line parallel to the rotation axis.

The specified object's name will appear in the **Axis 1** field.

3. Construct a vector specifying the axis direction. In this case, the word “Vector” will be displayed in the **Axis 1** field. The vector can be created with the **Vector Drawing** button on the Special Control Panel. For more information on drawing a vector, see Chapter 2.8.5 on p. 613.

The resulting axis direction is the **Forward Direction**. To reverse the axis direction, activate the **Reverse Direction** switch in the **Direction** group.

2.7.3.3.2. Grid Step along First Axis

To specify grid step along the first axis, complete the following steps.

1. Enter the number of copies in the direction of the first axis into field **N 1**.
2. Enter the value of step between copies into the **Step 1** field.
3. Activate the switch matching the specified value of step in the **Mode 1** group (see Table 2.7.3).

Tab. 2.7.3. Mode to specify a grid step

	Value of Mode option	Method to specify a step
	Step between adjacent instances	The system regards step value as the distance between the corresponding points of neighboring copies along the axis direction [*] . This option is convenient for placing a certain number of copies at a definite distance from each other.
	Step between boundary instances	The system regards step value as the distance between corresponding points of the first and the last copies along the axis direction [*] . This option is convenient for placing a certain number of copies on a line of the specific length.

^{*} If the number of copies along the axis direction is equal to two, then the result of the construction shall be the same for any position of the **Mode** switch.

The same results of construction an array can be reached under various positions of the **Mode** switch. To do this, you should take into account the following correlation:

$$L = (N - 1) \cdot I, \text{ where}$$

L is a step between outer instances,

N is the number of copies

I is the step between adjacent instances.

2.7.3.4. Grid parameters along the second axis

2.7.3.4.1. The second axis direction

To specify the second grid axis direction, enable the **Axis 2** switch on the property bar.

The second axis direction controls will be displayed on the Property bar.

You can specify the second axis direction as follows.

1. In the **Opening Angle** field enter the value of the angle between the grid axes;
2. Specify a guide object in the Design Tree or in the model window (for information about the guide object, see p.2 of Section 2.7.3.3.1 on p. 539). The object name will appear in the **Axis 2** field.
3. To create a vector which defines axis direction (see p.3of Section 2.7.3.3.1 on p. 539). In this case, the word “Vector” will be displayed in the **Axis 2** field.

The resulting axis direction is the **Forward Direction**. To reverse the axis direction, activate the **Reverse Direction** switch in the **Direction** group.

2.7.3.4.2. Grid Step along the Second Axis

The grid step parameters along the second axis are the same as the step parameters along the first axis (see Section 2.7.3.3.2 on p. 540). To specify them, use fields and switches **N 2**, **Step 2** and **Mode 2**.

2.7.3.5. Changing positions of instances in an array against the base one

By default, the number of the base instance (the instance that corresponds to the object to be copied) is 1.1 (see Fig. 2.7.22, a). Array instances numbers are described in section 2.7.1.1.2 on p. 510.

You can change the array instances' position with respect to the base instance by assigning a certain number to it in the array (see Fig. 2.7.22, b).

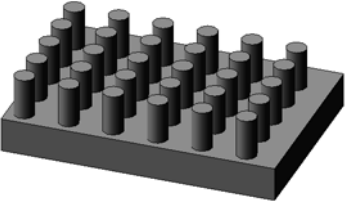

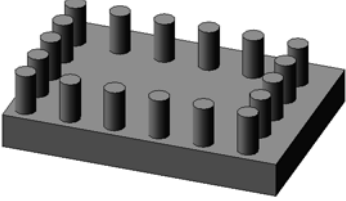

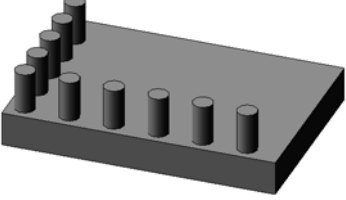

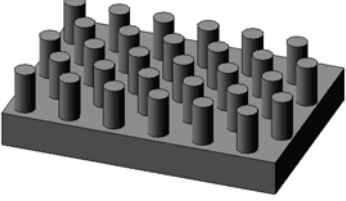

Fig. 2.7.22. Changing instances' position in an array against the base one (the base instance is highlighted in white color): a) base instance with number (1.1); b) base instance with number (2.2)

- ▼ To change the base instance's number in an array, enable the **Base instance** option on the property bar. Fields **Number 1** and **Number 2** will appear on the property bar. Enter or set with counter the required numbers of base instance by grid axes in these fields. The array's ghost will be re-build – the array's instances are positioned in such a way that the number of the base instance in the array corresponds to a given number.
- ▼ To restore the base instance's default number 1.1, disable the option. The array's ghost will be rebuilt– the instances will be positioned so that the base instance number is used by default.

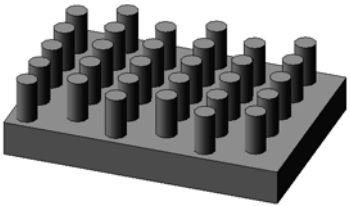

2.7.3.6. Positioning copies inside the grid

Positioning of array's instances and their number inside of the initially defined grid can be modified, for example, instances can be arranged along the grid's perimeter only or in chessboard fashion. In order to define a positioning variant, select a line from the **Scheme** list (Table 2.7.4).

Tab. 2.7.4. Control over copies inside the grid

	Positioning scheme	Procedure to create an array Construction result	
	Standard scheme	Array's instances are positioned in all nodes of the grid.	
	Delete Copies Inside Grid*	Array's instances are positioned along the perimeter of the grid.	
	Copy only along the axes**	Array's instances are positioned along the grid's axes only.	
	Staggered order — displacement along the first axis**	The instances are displaced with respect to nodes of the defined grid by half the step along the first axis. The displacement takes place in each even row of the current direction of the axis. The first row is the row containing the instance number (1, 1).	

Tab. 2.7.4. Control over copies inside the grid

	Positioning scheme	Procedure to create an array	Construction result
	Staggered order — displacement along the second axis**	The instances are displaced with respect to nodes of the defined grid by half the step along the second axis. The displacement takes place in each even row of the current direction of the axis. The first row is the row containing the instance number (1, 1).	

* The scheme makes sense, if the number of instances in both directions is three or more.

** The scheme makes sense, if the number of instances in both directions is two or more.

The position of the reference instance if positioned in chess-board fashion will not be changed.

2.7.4. Pattern by Circular Grid

You can create an array of objects by positioning them in concentric grid nodes, for example, as is shown on the Fig. 2.7.23.

Fig. 2.7.23. Example of array along circular grid

The grid formation scheme is described in Section 2.7.4.1 on p. 543, array construction procedure — in section 2.7.4.2 on p. 546.

2.7.4.1. Array construction scheme

The circular grid is characterized by the position of its plane and center, radii of circles and the angle between the respective radial rays (Fig. 2.7.24).

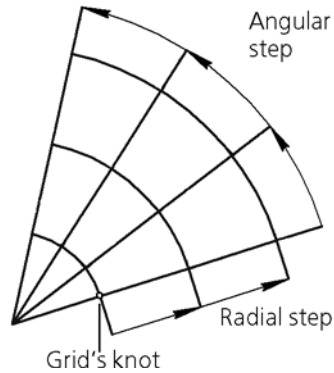

Fig. 2.7.24. Concentric grid of the array

The position of the grid's plane and its center is defined by the **array axis** and **base point of the base instance**.

Base point position can be **autodefined** or specified **manually**.

Array creation by concentric grid is described in Table. 2.7.5.

Copying of a group of objects has the following peculiarities.

Tab. 2.7.5. Constructing Array of Components by Circular Grid

Construction Spacing	Result*
1. The grid's plane going through the base point of the base instance perpendicular to the array's axis will be built.	
2. In the grid's plane, the first ray and the first circle of the grid going through the base point will be built. Thus, the base point of the base instance will become the first node of the grid.	
3. The remaining rays and circles of the grid are built and other nodes of the grid are determined in accordance with the grid's parameters.	

Tab. 2.7.5. Constructing Array of Components by Circular Grid

Construction Spacing

Result*

4. The base points of other array's instances are mated with the grid's nodes. The instances are positioned against their base points in the same way as the base instance is positioned against its base point.

5. If the Set Copies Radially option is enabled, each instance will be rotated in the grid's plane against its base point so that it is positioned against its ray the same way as the base instance is positioned against its base ray.

* The construction result is shown as a projection on the plane perpendicular to the array's axis.

If a group of objects is being copied, the array for all objects, except for operations, will be constructed as follows:

- ▼ If the base point is set manually, the group of objects will be copied as **a whole**: one grid is built for the group of objects to be copied; if additional turn is enabled, each instance (group of copies) will be rotated around its base point (Fig. 2.7.25, a).
- ▼ If a base point is autodefined, the group's objects will be copied separately: a separate grid will be created for each object; if additional turn is enabled, each object's copy will be rotated around its base point (Fig. 2.7.25,b).

The group of operations is always copied as a whole.

Fig. 2.7.25. Array of the group of objects along the concentric grid with additional turn:
a) point 1 is specified as the base point, b) base point is not specified

2.7.4.2. Constructing Array of Components by Circular Grid

To draw an array by circular grid, complete the following steps.

1. Call the **Array by Circular Grid** command.

Once the command has been called, the property bar will contain the **Choice of objects** tab (see Fig. 2.7.3 on p. 512).

2. Specify the **copied object**: operations or bodies or surfaces or curves, points, auxiliary planes and axes, or components.

For details about copied object selection, see Section 2.7.1.3.1 on p. 512.

The names of the selected objects will appear in the **List of Objects** toolbar.

The ghost of the **reference point of the object being copied** appears on the screen as three mutually perpendicular vectors (see Section 2.1.1.4 on p. 104).

Parameters, Deleted, Properties tabs will appear on the property bar.

You can also select objects for copying prior to calling the array creation command.

3. Go to the **Parameters** tab.

- 3.1. Specify the **array axis**. You can use any straight line object or revolution surface (except for sphere) as an array axis. Straight objects are listed in Table 2.1.7 on p. 131.

Enable the **Axis** switch on the property bar and specify the required object in the model window. Construction axes can also be selected in the Design Tree.

The object-axis name will appear in the **Axis** field.

Once the array's axis has been selected, the array's ghost appears on the screen together with arrows indicating the direction of adding instances with respect to copied elements. The grid shall be built with default settings. Using the ghost's hot points, you can change default parameters of the array's grid.

- 3.2. Enable the **Circular direction** switch in the **Direction** group. Specify **grid parameters in circular direction** (see Section 2.7.4.3 on p. 547).

3.3. Enable the **Radial direction** switch in the **Direction** group. Specify **grid parameters in radial direction** (see section 2.7.4.4 on p. 548).

3.4. Select **Orientation of Array Instances** (see Section 2.7.4.5 on p. 549).

All the changes will be reflected in the array ghost.

4. If required, you can also use the following options:

- ▼ Instance displacement along the **array's axis** (see Section 2.7.4.6 on p. 550).
- ▼ Changing array instances' positions with respect to the **base instance** — the instance which corresponds to the objects to be copied (see Section 2.7.4.7 on p. 551).
- ▼ Changing the position of the **base instance's reference point** (see Section 2.7.4.9 on p. 553).
- ▼ Disabling using the **projection of the reference point of the object being copied — available, if rotation bodies/surfaces are copied** (see Section 2.7.1.3.3 on p. 514).
- ▼ Creating a **geometric array** — available, if operations are copied (see Section 2.7.1.3.5 on p. 515).
- ▼ Deleting and restoring array instances. Enable the **Instances** tab of the Properties Bar. See Section 2.7.1.3.6 on p. 516 for information on the deletion and restoring array's instances.
- ▼ Managing form and dimensions of instances by changing their variables' values (see Section 2.7.2 on p. 519).
- ▼ Changing of array name and properties of surface of instances. Enable the **Properties** tab of the Property Bar.

5. Confirm array creation

Created array appears in the model window, while the icon attributable to its type is displayed in the Design Tree.

If base instance's reference point is on the array's axis, it is impossible to define the direction of the grid's first axis (and, consequently, of the other axes). The number of instances in the radial direction of such an array is always equal to 1. Changing this number, as well as other parameters of the grid in the radial direction, is not possible (the **In radial direction** switch is not available). Such an array is not defective. If it suits you, do not change its source objects. If it is necessary to change the grid's parameters in the radial direction, choose another array's axis or another base point.

2.7.4.3. Grid Parameters in Circular Direction

To set grid parameters in the circular direction, activate the **In Circular Direction** switch of the **Direction Selection** group. Once this switch is active, the Property Bar will display the controls for location of array instances in the circular direction.

Enter the number of circular grid beams into the **N 2** field. In other words, in this field you should specify how many copies shall be created on each circle of the grid.

If this number exceeds one, control features to specify grid step in the radial direction shall become accessible.

Enter the angle between grid beams into the **Step 2** field. In other words, specify the angle step between copies along the circular direction in this field. The value of this parameter cannot exceed 360°.

Activate the switch matching the specified value of step in the **Mode 2** group (see Table 2.7.6).

Tab. 2.7.6. Mode to specify a grid step

	Value of Mode option	Method to specify a step
	Step between adjacent instances	The system views the step value as the angle between grid neighboring beams*. This option is convenient for placing a certain number of copies at the known angle between them.
	Step between boundary instances	The system views the step value as the angle between the first and the last beams of the grid*. This option is convenient for spacing a certain number of copies evenly in circle or arc.

* If the number of copies along the circular direction is equal to two, then the result of the construction shall be the same for any position of the **Mode** switch.

The same results of construction an array can be reached under various positions of the **Mode** switch. To do this, you should take into account the following correlation:

$A = (N - 1) \cdot a$, where

A is the angle step between the boundary instances, and $A < 360^\circ$

N is the number of copies

a is the angle step between neighboring instances.

If $A = 360^\circ$, then copying is done along the whole circle, and

$A = N \cdot a$

Select the direction for adding instances against the elements to be copied: **Direct** or **Reverse**. To do this, activate the applicable switch in the **Direction** group. A displayed arrow indicates direction set by the currently active switch.

2.7.4.4. Grid Parameters in Radial Direction

To set grid parameters in the radial direction, activate the **In Radial Direction** switch of the **Direction Selection** group. Once this switch is active, the Property Bar will display the controls for location of array instances in the radial direction.

Enter the number of the circular grid circles into the **N 1** field. In other words, specify in this field how many copies should be obtained on each beam of the grid.

If this number exceeds one, control features to specify grid step in the radial direction shall become accessible.

Enter the distance between circles of the grid into the **Step 1** field. In other words, specify the step between copies along the radial direction in this field.

Activate the switch matching the specified value of step in the **Mode 1** group (see Table 2.7.7).

Tab. 2.7.7. Mode to specify a grid step

	Value of Mode option	Method to specify a step
	Step between adjacent instances	Value of step is viewed by system as the distance between neighboring circles of the grid*. This option is convenient for placing a certain number of copies at a definite distance from each other.
	Step between boundary instances	The system views the step value as the distance between extreme circles of the grid*. This option is convenient for placing a certain number of copies on a line of the specific length.

* If the number of copies along the radial direction is equal to two, then the result of the construction shall be the same for any position of the **Mode** switch.

The same results of construction an array can be reached under various positions of the **Mode** switch. To do this, you should take into account the following correlation:

$$L = (N - 1) \cdot I, \text{ where}$$

L is a step between outer instances,

N is the number of copies

I is the step between adjacent instances.

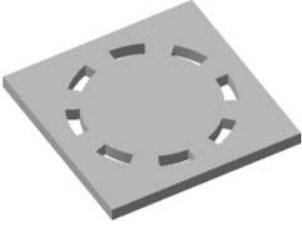

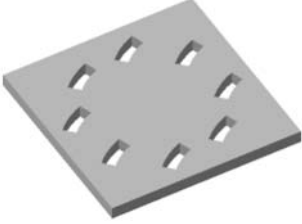

By default, instances are added against copied objects in the direction off the grid's center. The direction is **Direct**. To add instances centerwise, activate the **Reverse Direction** switch in the **Direction** group.

2.7.4.5. Array instances orientation

Instances in the array may keep the initial orientation or turn taking into account the grid angle step. To select a construction option, activate the required switch in the **Orientation** group (see Table 2.7.8).

Tab. 2.7.8. Orientation of circular array features

The value of the Orientation option	Procedure to rotate instances	Construction result
	<p>Each instance is rotated in the grid's plane around its base point so that it is positioned against its ray the same way as the base instance is positioned against its ray.</p>	
	<p>No instances rotation can be done.</p>	

2.7.4.6. Instance displacement along the array's axis

You can move instances along the **array's axis**, for example, as it is shown in Fig. 54.4.

Fig. 2.7.26. An example of an array along circular grid with instances' offset along the axis

In order to move instances along the **array's axis**, a number should be entered in the **Step along axis** field. The step value can be both positive and negative.

Positive axis direction is indicated by a straight arrow on the array's ghost.

If the step is equal to zero, all instances are in the same plane (Fig. 2.7.27, a).

If the step is not zero, the instances are moved along the array's axis (Fig. 2.7.27, b).

Fig. 2.7.27. Changing the array instances' positions when setting a step along the axis
a) zero step; b) step along the axis is different from zero.

The offset **T** value is calculated by the following formula:

$T = t \cdot (N - 1)$, where:

N is the number of the copy in the circular direction,

t is a step along the arrays' axis.

2.7.4.7. Changing positions of instances in an array against the base one

By default, the number of the base instance (the instance that corresponds to the object to be copied) is 1.1 (see Fig. 2.7.28, a). Array instances numbers are described in section 2.7.1.1.2 on p. 510.

You can change the array instances' position with respect to the base instance by assigning a certain number to it in the array (see Fig. 2.7.28, b).

Fig. 2.7.28. Changing instances' position in an array against the base instance
(the base instance is highlighted in white color): a) base instance with number (1.1);
b) base instance with number (1.2)

- ▼ To change the base instance's number in an array, enable the **Base instance** option on the property bar. Fields **Number 1** and **Number 2** will appear on the property bar. In these fields, enter the required numbers of the base instance in the circular and radial directions or set them

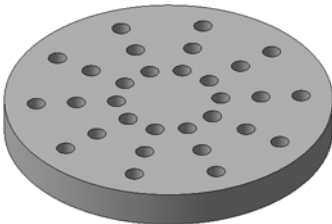

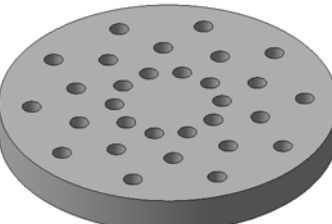

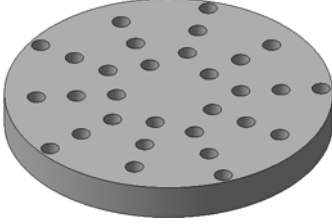

with counter. The array's ghost will be re-build – the array's instances are positioned in such a way that the number of the base instance in the array corresponds to a given number.

- ▼ To restore the base instance's default number 1.1, disable the option. The array's ghost will be rebuilt– the instances will be positioned so that the base instance number is used by default.

2.7.4.8. Positioning of copies inside the circular grid

Array's instances can be moved by half the step in the ring and radial directions. In order to specify the required variant of copies' positioning, select a line in the **Scheme list** (Table 2.7.9).

Tab. 2.7.9. Control over copies inside the circular grid

	Positioning scheme	Procedure to create an array	Construction result
	Standard scheme	Array's instances are positioned without an offset with respect to the defined grid's nodes.	
	Staggered order — displacement in the ring direction	Instances of ring rows are displaced along the nodes of the defined circular grid along the ring direction. The offset value is equal to half the distance of the arc's length between adjacent nodes of the grid. The displacement takes place in each even row in the instance building direction. The first row is the row containing the instance number (1, 1).	
	Staggered order — displacement in the radial direction	Instances of radial rows are displaced along the nodes of the defined circular grid by half the step along the ray. The displacement takes place in each even row in the instance building direction. The first row is the row containing the instance number (1, 1).	

The position of the reference instance if positioned in chess-board fashion will not be changed.

Variants of instances' positions in the staggered order make sense only in those cases when the number of instances in both direction is two or more.

2.7.4.9. Setting the position of the base instance's reference point

Base point position can be **autodefined** or specified **manually**.

The autodefine base point of the base instance is the **base point of the object to be copied** (see Section 2.1.1.4 on p. 104).

You can select the reference point setting method in the **Parameters** tab of the Property bar using the **Base point** group of switches.

By default, the base instance's reference point is the reference point of the object being copied. In this case, the **Base point** switch is active in the group **Autodefinition**.

In order to manually set the reference point's position, enable the **Manual** setting switch. The **Base point of the base instance** switch appears on the Property Bar (automatically enabled) together with the **Object** informational field. Specify the required point object in the Model Tree or window (point objects are listed in Table 2.1.7 on p. 131). The name of the selected object shall be displayed in the field beside the switch.

When copying a group of objects by circular grid, there certain peculiarities depending on whether the reference point is autodefined or set manually (see Section 2.7.4.1 on p. 543).

2.7.5. Array along the curve

You can create an array of objects by positioning them along the specified curve, for example, as is shown on the Fig. 2.7.29.

Fig. 2.7.29. Example of a Path Array

The array creation scheme is described in Section 2.7.5.1 on p. 554, array construction procedure — in Section 2.7.5.2 on p. 555.

2.7.5.1. Array construction scheme

The array along the curve is constructed in a different way depending on if the base point of the base instance is set or not.

If the base point is **set**, the array will be constructed as follows:

1. **Copying path** is found.
 - 1.1. A copy of the specified curve will be built. a curve is moved parallel to itself to make its starting point coincide with the **base point of the base instance (B)**.
 - 1.2. A segment is created to connect the base point of the base instance (B) with the **base point of the copied object (A)**.
 - 1.3. A **swept surface** is built by moving the AB segment along the curve's copy. The surface's edge opposite to the curve's copy is the copying path.
2. The array's instance is considered a separate object with a base point — **base point of the copy**. Base points of copies are positioned on the copying path in accordance with the preset copying step.
3. If additional turn is enabled, each copy is rotated around its base point (see. Section 2.7.5.6 on p. 559).

Diagram of the array construction in the above-described way is detailed in Fig. 2.7.30, a.

If the base point is **not set**, the array will be constructed as follows:

1. **Copying path** is found. To do this, a copy of the curve is created: a curve is moved parallel to itself to make its starting point coincide with the **base point of the copied object (A)**. The resulting copy of the curve will be the copying path.
2. Base points of copies (see above) are positioned on the copying path in accordance with the preset copying step.
3. If additional turn is enabled, each copy is rotated around its base point (see. Section 2.7.5.6 on p. 559).

Diagram for constructing the array in the above-described way is detailed in Fig. 2.7.30, b.

Fig. 2.7.30. Diagram for copying the extrusion feature along the whole guiding line while maintaining the orientation (path and the copied object are highlighted):
 a) point **B** is chosen as the base point of the base instance,
 b) position of the base instance's base point is not set

2.7.5.2. Procedure of the array creation along the curve

To create a path array, perform the following steps.

1. Call the **Array along curve** command.

Once the command has been called, the property bar will contain the **Choice of objects** tab (see Fig. 2.7.3 on p. 512).

2. Specify the **copied object**: operations or bodies or surfaces or curves, points, auxiliary planes and axes, or components.

For details about copied object selection, see Section 2.7.1.3.1 on p. 512.

The names of the selected objects will appear in the **List of Objects** toolbar.

The ghost of the **reference point of the object being copied** appears on the screen as three mutually perpendicular vectors (see Section 2.1.1.4 on p. 104).

Parameters, Deleted, Properties tabs will appear on the property bar.

You can also select objects for copying prior to calling the array creation command.

3. Go to the **Parameters** tab.
 - 3.1. Specify a **curve** to create an array.

The following may be used as this curve:

- ▼ a 3D curve,
- ▼ an edge,
- ▼ a sketch line,
- ▼ a chain of objects listed above in any combination.

Enable the **Curve** switch and specify the required object or objects in the Design Tree or in the model window. The name of the selected object or the number of selected objects are shown in the **Curve** field. To cancel object selection, re-select it.

The array ghost will be displayed. The starting point of the specified curve is used as the **base point of the base instance** (the extreme point of the curve nearest to the copied object). It depends on mutual position of the copied object and the starting point of the curve (see Section 2.7.5.7 on p. 559).

- 3.2. If necessary, set the **starting point** of the curve manually, if the copying path is closed (see Section 2.7.5.3 on p. 556).
- 3.3. Enter the number of copies into the **Number** field.
- 3.4. Specify the **copying step** (see Section 2.7.5.4 on p. 556).
- 3.5. If necessary, use the switches of the **Direction** group to change the **direction of copying** suggested by the system (see Section 2.7.5.5 on p. 558).
- 3.6. Select **Orientation of instances** (see Section 2.7.5.6 on p. 559).

All the changes will be reflected in the array ghost.

4. If required, you can also:
 - ▼ Changing the position of the **base instance's reference point** (see Section 2.7.5.7 on p. 559).

- ▼ Disabling using the **projection of the reference point of the object being copied — available, if rotation bodies/surfaces are copied** (see Section 2.7.1.3.3 on p. 514).
- ▼ Creating a **geometric array** — available, if operations are copied (see Section 2.7.1.3.5 on p. 515).
- ▼ Deleting and restoring array instances. Enable the **Instances** tab of the Properties Bar. See Section 2.7.1.3.6 on p. 516 for information on the deletion and restoring array's instances.
- ▼ Managing form and dimensions of instances by changing their variables' values (see Section 2.7.2 on p. 519).
- ▼ Changing of array name and properties of surface of instances. Enable the **Properties** tab of the Property Bar.

5. Confirm array creation

Created array appears in the model window, while the icon attributable to its type is displayed in the Design Tree.

2.7.5.3. Curve start point

The starting point of an **open** path is its end point closest to the object being copied.

The starting point of a **closed** path is its first vertex (for a chain of objects— the vertex nearest to the copied object).

If necessary, you can **manually** define the starting point of a closed path. You can specify any point on the path as the starting point.

Activate the **Start point** switch on **Parameters** tab of Properties toolbar and select the required point in the model window. The name of the selected object is displayed in a field beside the switch. To cancel object selection, re-select it.

Dependence of array instances disposition from the starting point selection is shown in Fig. 2.7.31.

Fig. 2.7.31. Relation between disposition of copies and location of the start point of the curve.
(copying path and the object to be copied are highlighted, starting point is indicated by a circle)

2.7.5.4. Copying step

Copies can be placed evenly along the whole guiding line or at a specified distance from each other. To select a construction option, activate the applicable switch in the **Method** group (see Table 2.7.10).

Tab. 2.7.10. Methods to set array step

Value of option Method	Concept of determining the copying step
 By Step	<p>You can set a step value and select a mode of step determination* :</p> <ul style="list-style-type: none"> ▼ between neighboring copies or ▼ between boundary copies. <p>Enter into Step field the value of a step between copies which is measured along the copy path.</p> <p>Activate the switch matching the specified value of step in the Mode group (see Table 2.7.11).</p>
 Along the Entire Guiding Line	<p>Full step is determined automatically as the length of the copying path. The first and the final array instances lie at the start and the end points of the guiding curve. Array instances are spaced evenly along the path. Field Step and group Mode are not present on the property bar.</p>

* If the value of full step is set as equal to the length of path, then the result of construction shall be the same as for the **Along Whole Guiding Line constructing** method.

Tab. 2.7.11. Mode of setting step along the path

Value of Mode option	Method to define a step
 Step between adjacent instances	<p>The system views the step value as spacing between corresponding insertion points of neighboring copies in the direction of copying* . This option is convenient for placing a certain number of copies at a definite distance from each other.</p>
 Step between boundary instances	<p>The system views the step value as spacing between corresponding insertion points of the first and the second copies in the direction of copying* . This option is convenient for placing a certain number of copies on a line of the specific length.</p>

* If the number of copies is equal to two, then the result of construction is the same for any position of the **Mode** switch.

The same results can be reached under various positions of the **Mode** switch. To do this, you should take into account the following correlation:

$$L = (N - 1) \cdot I, \text{ where}$$

L is the step between the extreme instances measured along the path

N is the number of copies

I is the step between neighboring instances measured along the path.

2.7.5.5. Direction of copying along the path

While creating an array along curve, you can direct the copying using switches of the **Direction** group.

A change in the direction has a different effect on arrays with closed and open path.

If the path is closed, then the **Forward Direction** of copying means placing array instances along the path on the same side of the copied object, while the **Reverse Direction** means placing them on the other side (Fig. 2.7.32). The current copying direction is shown by the arrow on the array ghost.

Fig. 2.7.32. Change of direction for the array with closed path:
a) copied object and path (marked with a thicker line),
b) array in forward direction, c) array in reverse direction

If the copying path is closed, and instances are positioned along the whole guiding line (see Table 2.7.7 on p. 549), the operation's result does not depend on the copying direction.

If the path is open, then the **Forward Direction** of copying means the start of the path is defined by default and the starting point is the path's end nearest to the copied object. When selecting the **Reverse Direction**, the other end will be considered as the path start (Fig. 2.7.33).

Fig. 2.7.33. Change of direction for the array with an open path:
a) the copied object and path,
b) array in forward direction, c) array in reverse direction

2.7.5.6. Orientation of Array Instances

Copies in the array can maintain the initial orientation or rotate taking into account the curvature of the path. To select a construction option, activate the required switch in the **Orientation** group (see Table 2.7.12).

Tab. 2.7.12. Copies Orientation along the Path

	The value of the Orientation option	Procedure to rotate copies	Construction result
	Save initial orientation	No copies rotation can be done.	
	Set Radially to Normal	Each copy is rotated so that it gets oriented with respect to the tangent path vector in its base point, the same way as the copied object is oriented with respect to the tangent path vector in its base point.	

2.7.5.7. Setting the position of the base instance's reference point

Base point position can be **autodefined** or specified **manually**.

The autodefine base point of the base instance is the **base point of the object to be copied** (see Section 2.1.1.4 on p. 104).

The array building result depends on the method of defining the reference point (see Section 2.7.5.1 on p. 554).

You can select the reference point setting method in the **Parameters** tab of the Property bar using the **Base point** group of switches.

If the reference point of the object being copied coincides with the curve's starting point and is positioned on the tangent to the curve in this point, the **Autodefine** switch is enabled by default.

In other cases, the **Manual setting** switch is enabled. And the starting point of the specified curve is suggested as the base point of the base instance (the extreme point of the curve nearest to the copied object). The reference point's name will be displayed in the **Object** field.

If it is necessary to change the base point, enable the **Base point of the base instance** switch in the **Base point** group and specify the required point object in the Design Tree or model window (point objects are listed in Table 2.1.7 on p. 131).

If necessary, you can change the reference point setting method. To do this, enable the respective switch. **Autodefine** or **Manual setting**.

To get a predictable result of copying:

- ▼ when using the manual definition of the base point, it is recommended to select the path start as the base point.
- ▼ when using auto determination of the base point, it is recommended to create the path in such a way that it would definitely start in the base point of the object being copied.

2.7.6. Pattern by Points

You can create an array of objects, whose instances' positions are set by point objects (Fig. 2.7.34). Point objects are listed in Table 2.1.7 on p. 131.

Fig. 2.7.34. Example of an array by points

2.7.6.1. Creating an array by points

To create an array by points, complete the following steps.

1. Call the **Array by Points** command.

Once the command has been called, the property bar will contain the **Choice of objects** tab (see Fig. 2.7.3 on p. 512).

2. Specify the **copied object**: operations or bodies or surfaces or curves, points, auxiliary planes and axes, or components.

For details about copied object selection, see Section 2.7.1.3.1 on p. 512.

The names of the selected objects shall appear in the **List of Objects** toolbar.

The ghost of the **reference point of the object being copied** appears on the screen as three mutually perpendicular vectors (see Section 2.1.1.4 on p. 104).

Parameters, Deleted, Properties tabs will appear on the property bar.

You can also select objects for copying prior to calling the array creation command.

3. Go to the **Parameters** tab.

- 3.1. Specify **positions** of the array's instances. To do this, activate the **Points** switch and specify the required point objects in the Design Tree or in the model window (point objects are listed in Table 2.1.7 on p. 131). Specified point objects are color highlighted.

The name of the selected object or the number of selected objects are shown in the **Points** field. To cancel object selection, re-select it.

The array ghost will be displayed: the base point of the base instance is the base point of the copied object; base points of other instances of the array will coincide with the indicated points.

If array instance positions are set by the group points or sketch points, you can select the required points in the Design Tree or in the model window. To select all points of group or sketch, specify this group or sketch in the Design Tree.

If the sketch specified in the Design Tree is used to specify instances' positions, you can control the plane where these instances are positioned (see Section 2.7.6.2 on p. 561).

3.2. Select **Orientation of instances method** (see Section 2.7.6.3 on p. 562).

All the changes will be reflected in the array ghost.

4. If required, you can also:

- ▼ Changing the position of the **base instance's reference point** (see Section 2.7.4.9 on p. 553).
- ▼ Disabling using the **projection of the reference point of the object being copied; it is available, if rotation bodies/surfaces are copied** (see Section 2.7.1.3.3 on p. 514).
- ▼ Creating a **geometric array** — available, if operations are copied (see Section 2.7.1.3.5 on p. 515).
- ▼ Deleting and restoring array instances. Enable the **Instances** tab of the Properties Bar. See Section 2.7.1.3.6 on p. 516 for information on the deletion and restoring array's instances.
- ▼ Managing form and dimensions of instances by changing their variables' values (see Section 2.7.2 on p. 519).
- ▼ Changing of array name and properties of surface of instances. Enable the **Properties** tab of the Property Bar.

5. Confirm array creation

Created array appears in the model window, while the icon attributable to its type is displayed in the Design Tree.

Number of copies of the source object is equal to the number of points defining array instances positions (n).

If one of copies coincides with the source object, this copy will not be created. Number of one object copies is equal to $n-1$.

2.7.6.2. Control of the plane of the array instances' position

When setting positions of the array's instances, you can use the sketch with points. In this case, all points of the sketch will be used for the array creation.

To set sketches' positions using all points of the sketch, enable the **Points** switch on the **Parameters** tab and specify the required sketch in the Design Tree.

The **Project** option will appear on the property bar that controls the plane of the instances' positions set by the points of the specified sketch.

If the option is enabled, the array will be built as follows (Fig. 2.7.35,a).

1. An additional plane is created parallel to the sketch plane and passing through the base *C* point of the object of copying.
2. Projections of sketch points to the additional plane are created.
3. Instances are positioned so that their base points coincide the projected points of the sketch on the additional plane.

If the option is disabled, the instances of the array are positioned so that their base points coincide the points in the sketch (Fig. 2.7.35,b).

Fig. 2.7.35. Setting positions of array instances:
a) if the **Project** option is enabled; b) if the **Project** option is disabled

2.7.6.3. Orientation of Array Instances

Array's instances can maintain their initial orientation or be rotated.

To select an instance construction option, activate the required switch in the **Orientation** group on the Property Bar:

- ▼ **Save initial orientation** (see Section 2.7.6.3.1 on p. 562),

- ▼ **Orient by object related to point** (see Section 2.7.6.3.2 on p. 563),

- ▼ **Orient by specified object** (see Section 2.7.6.3.3 on p. 564).

2.7.6.3.1. Construction of instances with initial orientation

You can create array instances with their initial orientation. Each instance's orientation in its base point will be the same as orientation of the copied object in its base point (Fig. 2.7.36).

Fig. 2.7.36. Positioning array instances with their initial orientation

In order to position instances with their initial orientation, enable the **Keep initial orientation** switch in the **Orientation** group on the Property Bar. After enabling the switch, all instances will be oriented in space in the same way as the copied object.

2.7.6.3.2. Construction of instances with orientation by object linked to points

Positions of array instances may be defined by points on the curve or on the surface. Such points include:

- ▼ points built by the **Group of points on curve** command or **Group of points on surface** (see Sections 2.5.3.2 on p. 350 and 2.5.3.3 on p. 353);
- ▼ points built by the **Point** command using the **On curve** or **On surface** method (see Sections 2.5.2.5 on p. 338 and 2.5.2.6 on p. 339);

If positions of instances are defined by the above-mentioned points, you can orient instances with respect to the object(s) on which points are positioned. For purpose, use the **Orient by object linked to point** switch of the **Orientation** group on the Property Bar.

Once the switch is enabled, instances will be oriented in the following way:

▼ Points on curve

Each instance is rotated around its reference point so that it gets oriented with respect to the tangent curve vector in this point, the same way as the copied object is oriented with respect to the tangent curve vector in this curve's point which is closest to the reference point of the object being copied (Fig. 2.7.37, a).

▼ Points on surface

Each instance is rotated around its reference point so that it gets oriented with respect to the surface's normal in this point, the same way as the copied object is oriented with respect to the surface's normal in this curve's point which is closest to the reference point of the object being copied (Fig. 2.7.37, b).

Fig. 2.7.37. Example of array instances positioning:
a) with orientation by curve; b) with orientation by surface

The set of points that define positions of instances may include points that are positioned on a curve or surface. In this case, once the **Orient by object linked to point** switch is enabled, the instances with positions defined by these points will be oriented in space in the same way as the copied object.

The **Orient by object linked to point switch** is not available, if

- ▼ all points that define positions of instances are not positioned on a surface or curve,
- ▼ all points that define positions of instances are positioned on a flat surface or linear curve,
- ▼ the base point of the object being copied is not projected on the surface or curve to which the points belong.

2.7.6.3.3. Construction of instances with orientation by specified object

Array's instances can be oriented by a normal to the specified object. The following may be used as the object:

- ▼ an edge, 3D curve, or sketch line (except for straight lines);
- ▼ face (except for flat ones).

Example of positioning array instances with orientation by a spheric face is shown in Fig. 2.7.38.

Fig. 2.7.38. Example of array instances positioning
(the base instance is highlighted):

a) with the initial orientation retained; b) with orientation by spherical face

In order to change orientation of instances in space with respect to an object, enable the **Orient by specified object** switch. The **Object** field will appear next to the switch on the Property Bar.

Specify the required object. The specified object is highlighted by a certain color, and its name is displayed in the **Object** field.

Orientation of the instance is defined as follows.

1. The nearest projection of the point, that defines the instance's position, to the specified object will be built (Point *A*).
2. The nearest projection of the base point of the base instance to the specified object will be built (Point *B*).
3. The instance is rotated around its base point so that it is oriented with respect to the normal to the specified object in the *A* point in the same way as the copied object is oriented with respect to the normal to the specified object in point *B*.

If no projections on the specified object are built for points that define the instances position, the instances related to these points will be oriented in space in the same way as the copied object.

2.7.7. Array by Table

You can create an object array, which instances positions are set by points. Positions of points, in their turn, can be set using two methods:

- ▼ by reading coordinates saved in the data file (see Appendix VI for more information about the data file),
- ▼ manual entry of coordinates in the table of modifiable variables which is saved in the model.

Values read from the data file or specified in the table of modifiable variables can be interpreted as rectangular, cylindrical, or spherical coordinates of points (more information about types of a point's coordinates can be found in Section 2.5.3.4.1 on p. 358).

If instances' positions are specified using the data file, link between the created array and the data file will be kept.

Another way of using the **Array by points** command is to get an array of objects which differ in parameters only (i.e. only values of their variables differ). For example, you can build copies of the extrusion operation which have differences only in the following parameters:

- ▼ values of dimensions which define the position of a contour in a sketch counting from the zero point of the coordinates of this sketch (dimensions in the sketch must be set before the array is created),
- ▼ values of a variable which defines the extrusion depth.

The resulting extrusion operations will apply to the same section but will differ in length and position.

Table array relates to objects that use coordinate system (for object coordinate system refer to Section 2.8.3.4.1 on p. 598).

2.7.7.1. Creation of an array using table

You can create an array from a table in two ways:

1. An array of objects of a specific type, e.g. operations. In this case you will be able to set the positions and orientation of the instances. You can change the values of the variables for instances if required. And vice versa, you can set only values of variables without setting their positions.
2. An array of an arbitrary objects. In this case you will not be able to set the positions and orientation of the instances To avoid duplicating of the instances, change the values of their variables.

The limitation of the second option is that you cannot copy bodies, components and previously created arrays.

Option 1 Array of objects of selected type

1. Call the **Array by table** command.

Once the command has been called, the property bar will contain the **Choice of objects** tab (see Fig. 2.7.3 on p. 512).

2. Specify the **copied object**: operations or bodies or surfaces or curves, points, auxiliary planes and axes, or components.

For details about copied object selection, see Section 2.7.1.3.1 on p. 512.

The names of the selected objects will appear in the **List of Objects** toolbar.

The ghost of the **reference point of the object being copied** appears on the screen as three mutually perpendicular vectors (see Section 2.1.1.4 on p. 104).

Parameters, Deleted, Properties tabs will appear on the property bar.

You can also select objects for copying prior to calling the array creation command.

3. Go to the **Parameters** tab.
 - 3.1. Set **positions** of instances (see Section 2.7.7.2 on p. 568).
 - 3.2. Select the **coordinate type** for interpretation of data (from the table of modifiable variables or from the data file; more information about types of coordinates of a point can be found in Section 2.5.3.4.1 on p. 358). To do this, activate the relevant switch in the **Coordinate Type** group on the Properties bar:

- ▼ **Rectangular X,Y,Z,**

- ▼ **Cylindrical R,A,Z,**

- ▼ **Spherical R,A,B**

Points for setting the positions of instances will be built in the coordinate system which corresponds to the selected type.

Note that values of coordinates will be kept in case of changing their type. These values will be assigned to coordinates of the selected type.

If the type of coordinates is changed when working with the table of modifiable variables (the **Table of modifiable variables** window is open), you can:

- ▼ *save values of coordinates* – assign current values of coordinates to coordinates of the selected type,
- ▼ *recalculate coordinate values* – current values of coordinates will be changed in accordance with the selected type of coordinates.

A dialog will appear allowing you to choose the desired action. Click the **Yes** button to save the coordinate values or the **No** button to recalculate coordinate values.

- 3.3. Select **Orientation of instances method** for the array (see Section 2.7.7.4 on p. 574). All the changes will be reflected in the array ghost.
4. If required, you can also:
 - ▼ Changing the position of the **base instance's reference point** (see Section 2.7.4.9 on p. 553).
 - ▼ Disabling using the **projection of the reference point of the object being copied; it is available, if rotation bodies/surfaces are copied** (see Section 2.7.1.3.3 on p. 514).

- ▼ Creating a **geometric array**; it is available, if operations are copied (see Section 2.7.1.3.5 on p. 515).
- ▼ Deleting and restoring array instances. Enable the **Instances** tab of the Properties Bar. See Section 2.7.1.3.6 on p. 516 for information on the deletion and restoring array's instances.
- ▼ Changing of array name and properties of surface of instances. Enable the **Properties** tab of the Property Bar.

5. Confirm array creation

Created array appears in the model window, while the icon attributable to its type is displayed in the Design Tree.

Option 2 An array of an arbitrary objects

1. Call the **Array by table** command.

Once the command has been called, the property bar will contain the **Choice of objects** tab (see Fig. 2.7.3 on p. 512).

2. Specify the **objects to copy**.

2.1. In the **Type** group, enable the **Arbitrary** switch. **Parameters** and **Properties** tabs will appear on the Property bar.

- 2.1. Specify the required object in the Design Tree or Model Window.

If you choose objects using the Tree, then the objects between the specified ones will also be included when the **Select the intermediate items** option is enabled¹ (when the Tree displays the sequence of steps for building a model).

The names of the selected objects will appear in the **List of Objects** toolbar.

3. Set the variables related to the position, form and dimensions of the instances. To do this, click the **Table of modifiable variables** button on the Special Control Panel. In the table that appears add a line for each instance to be built, choose the modifiable variables and set their values (see Section 2.7.2 on p. 519 for details).

4. If necessary, change the name and properties of the created surface. Enable the **Properties** tab of the Property Bar.

5. Confirm array creation

Created array appears in the model window, while the icon attributable to its type is displayed in the Design Tree.

When using method 2, no ghost of the array is shown.

You can remove or restore the array instances as required. To remove a previously created array, choose the instance you want to delete and then press *<Delete>*. To restore the removed instances of an array when editing, use the **Instances** tab on the Properties bar. See Section 2.7.1.3.6 on p. 516 for information on the deletion and restoring array's instances.

1. The objects which cannot be copied are not included into the selection.

2.7.7.2. Setting positions of instances

Positions of points, that define positions of instances, can be set using two methods:

- ▼ by reading coordinates saved in the data file (see Appendix VI for more information about the data file),
- ▼ by manual entry of coordinates in the table of modifiable variables, which is saved in the model (see Section 2.7.2.2 on p. 521 for more information about the table of modifiable variables).

The **Source of data** group of switches on the **Parameters** tab makes it possible to choose the method of specifying instances' positions:

- ▼ **Source file** – reading data from file (see Section 2.7.7.2.1 on p. 568),

- ▼ **Manual entry** – manual entry of data in the table of modifiable variables (see Section 2.7.7.2.2 on p. 569).

Peculiarities of using the table of modifiable variables are described in Section 2.7.7.3 on p. 572.

2.7.7.2.1. Reading data from file

This method makes it possible to specify instances' positions by points the coordinates of which are obtained from a previously created file (see Appendix VI for more information about the data file).

To set instances' positions, complete the following steps.

1. Go to the **Parameters** tab of the Property Bar and click the **Source file** button in the **Data source** group.
2. The standard Windows File Open dialog shall appear on the screen. Specify a file name and click the **Open** button. The name of the file will appear in the **Source File** field.

The array ghost will be displayed: the base point of the base instance is the base point of the copied object; base points of other instances of the array will coincide with the points whose coordinates are obtained from the data file. These points will be highlighted with a color.

More information about the base point of the copied object can be found in Section 2.1.1.4 on p. 104; see Section 2.7.1.1.1 on p. 510 for more information about the base point of the array's instance.

You can view data read from file in the **Table of modifiable variables** window. For this, do the following.

1. Click the **Table of modifiable variables** button on the Special Control Panel. The **table of variables** will be displayed on the screen.

2. If no coordinates are listed in the table, enable them by clicking **Set coordinates of the base point** on the window toolbar.

Columns with coordinates of instances' base points appear in the table of modifiable variables (Fig. 2.7.39). Coordinate values of the copied object's base point are displayed in the second row. Each row of the table, starting from the third one contains the instance's number and coordinates of the point defining its position.

Note that columns with coordinates are displayed in gray color. It means that values of coordinates are not available for editing.

Instance	X	Y	Z
(1)	-15	30	0
(2)	-21	120	94
(3)	-94	57	53
(4)	5	102	73
(5)	16	96	23

Fig. 2.7.39. Example of the table of modifiable variables with coordinates obtained from file

The link between the created array and the data file is maintained. This link is, in general, similar to the link between a group of points and the source file (see Section 2.5.3.4.2 on p. 359). The difference is in link management: it is impossible not to create it during array construction (no **Explode** option on the Property Bar).

2.7.7.2.2. Manual entry of data in the table

This method makes it possible to set instances' positions by manual entry of coordinates of instances' base points in the table of modifiable variables (see Section 2.7.2.2 on p. 521 for information about the table of modifiable variables).

To set instances' positions, complete the following steps.

1. Go to the **Parameters** tab of the Property Bar and click the **Manual entry** button in the **Data source** group. The **Table of modifiable variables** command will be run automatically (its button can be found on the Property Bar).

The **Table of modifiable variables** appears on the screen with the table having the following structure (initial layout of the table; Fig. 2.7.40):

- ▼ The first row contains the names of coordinates (headers of columns).
- ▼ Coordinate values of the copied object's base point are displayed in the second row.
- ▼ The remaining rows of the table contain numbers of instances and empty cells (by default, three rows are created in the table).

An empty cell of the table of modifiable variables means that the coordinate in the cell has the same value as the value of the respective coordinate of the base instance's point.

Fig. 2.7.40. Example of the table of modifiable variables for entry of coordinates (initial layout of the table)

Note that coordinates are displayed in the table if the **Set coordinates of the base point** button is enabled in the toolbar of the **Table of modifiable variables** window.

2. Specify the required number of instances (rows in the table) and enter new coordinates of the instances' base points in the table. New coordinates can be entered using two methods:
 - ▼ by entering coordinates in the table's cells (Method 1),
 - ▼ by specifying an increment value for coordinates (Method 2).
 Methods of filling the table are described in detail in this section below.
3. Click **OK** to close the **Table of modifiable variables** window.

The table with coordinates of instances' base points is added to the current file.

The array ghost will be displayed: the base point of the base instance is the base point of the copied object; base points of other instances of the array will coincide with the points whose coordinates are set in the table of modifiable variables.

If a value outside the range is entered in the table's cell, the table will not be closed after clicking **OK**. A message will appear informing that the values is outside the range, and the cell's borders will be highlighted. The range of acceptable values depends on the parameter to which it corresponds. For example, this message may appear if a negative value is entered in the cell of the *B* coordinate of the spherical system of coordinates, since the range of acceptable values of this coordinate is $0^\circ \dots 180^\circ$.

See Section 2.7.2.2.3 on p. 524 for details about working with the table of modifiable variables.

Editing coordinates in the table of modifiable variables is the same as their entry. In order to begin editing the table, click the **Table of modifiable variables** button on the Special Control Panel.

Methods of filling the table of modifiable variables by coordinates of points that define instances' positions

Method 1

Entry of coordinates of points that define instances' positions in the table of modifiable variables.

1. In order to use this method, click the **Values of Variables** button in the **Table of modifiable variables** window. The table of modifiable variables will appear in the window in its initial layout (Fig. 2.7.40).
2. Specify the required number of instances. For this purpose, change the number of rows in the table using the following buttons:

▼ **Add row above,**

▼ **Add row below,**

▼ **Delete rows.**

Note that cells of the new row added to the table are empty. An empty cell means that the coordinate in the cell has the same value as the value of the respective coordinate of the base instance's point.

3. Enter new coordinates of instances' base points in the table. For this purpose, activate the required cell by double-clicking it, enter the new coordinate's value and click <Enter>.

Method 2

Setting increment value for coordinates of instances' base points.

1. In order to use this method, click the **Increment value** button in the **Table of modifiable variables** window.

A table with the following structure will appear in the window (Fig. 2.7.41):

- ▼ The first row, starting from the third cell, contains the names of coordinates (headers of columns).
- ▼ The second column is used for setting the number of instances.
- ▼ The second row, starting from the third one, contains coordinates of the base point of the copied object.
- ▼ The third row is used for setting the increment value for coordinates.

	Of instances	X	Y	Z
Value	3	-15	30	0
Step				

Fig. 2.7.41. Example of the table of modifiable variables for setting the increment value of coordinates

2. Specify the required number of instances.
 - 2.1. Activate the required cell by double-clicking it in the second row and enter the required number of array instances in it.

- 2.2. Press <Enter>.
3. Specify the increment values for coordinates.
 - 3.1. In the third row of the table, activate the required cell by double-clicking it and enter the increment value for coordinates it (the increment value can both positive and negative).
 - 3.2. Press <Enter>.

If necessary, you can view the new coordinates of points. For this purpose, click the **Values of Variables** button in the **Table of modifiable variables** window. The table with coordinates will be displayed in the window. The column of the coordinate, for which increment value was assigned, will contain its new values.

2.7.7.3. Peculiarities of using the table of modifiable variables

Specifying positions of instances

One of the methods of setting positions of array's instances by table is reading coordinates of points from the data file. The table of modifiable values makes it possible to view coordinates obtained from the file.

In order to enable displaying coordinates in the table, click the **Set coordinates of the base point** button in the toolbar of the **Table of modifiable variables** window. Columns with coordinates will appear in the table (Fig. 2.7.42). Note that columns with coordinates are displayed in gray color. It means that values of coordinates are not available for editing.

Instance	X	Y	Z
	-15	30	0
(1)	379	54	-101
(2)	50	240	90
(3)	50	500	63
(4)	37	5	-10

Fig. 2.7.42. Example of the table of modifiable variables with coordinates obtained from file

Another method of specifying instances' positions is manual entry of coordinates of the instances' base points in the table of modifiable variables. Table cells for entering values of coordinates have white color (Fig. 2.7.43). It means that values in these cells can be modified. The exception is the row with coordinates of the base point of the copied object (the row is gray); these coordinates cannot be edited.

Instance	X	Y	Z
(1)	-15	30	0
(2)	-15	30	20
(3)	-25	45	25
(4)	-35	60	40
(4)	-45	75	65

Fig. 2.7.43. Example of the table of modifiable variables with coordinates set manually

Setting a new value of an instance's variable

New values of variables for array instances by table can be obtained from the data file (see Appendix VI). For this purpose, the **Read from file** button is used. The table of modified variables is filled with data from file as follows: values are entered only in the cells that are displayed in the table at the moment the data is read and are available for editing (they are white).

Let's take the table of modifiable values illustrated in Fig. 2.7.44 as an example. The table contains columns with coordinates of instances' base points and columns with values of variables for instances.

In Fig. 2.7.44, a) cells with coordinates are not available for editing, cells with values of variables are available. Values from the data file will be entered only in those cells that are available for editing (in variables' columns).

In Fig. 2.7.44, b) cells with coordinates' values and cells with variables' values are both available for editing. Values from the data file will replace the contents of all cells that are available for editing.

To keep the values of coordinates' base points unchanged, disable displaying them in the table. You can do this using the **Specify base point coordinates** button. Then, values from the data file will be entered only in the remaining cells of the table (in variables' columns).

Instance	X	Y	Z	v12	v134
(1)	379	54	-101	20	25
(2)	50	240	90		
(3)	50	500	63		
(4)	37	5	-10		

a)

Fig. 2.7.44. Example of the table of modified variables:
a) coordinates of instances' base points are not available for editing;
b) coordinates of instances' base points are available for editing

Instance	X	Y	Z	v12	v134
	-15	30	0	20	25
(1)	379	54	-101		
(2)	50	240	90		
(3)	50	500	63		
(4)	37	5	-10		

b)

Fig. 2.7.44. Example of the table of modified variables:
 a) coordinates of instances' base points are not available for editing;
 b) coordinates of instances' base points are available for editing

If the file has more lines than the table when reading the data file, then:

- ▼ For the table in which cells with coordinates values are available for editing (Fig. 2.7.44, b) a prompt to add more lines will be displayed.
Click **Yes** to add more lines. To cancel adding lines, click **No**.
- ▼ For the table in which cells with coordinates values are not available for editing (Fig. 2.7.44, a) no prompt to add more lines is displayed. Data from file are entered only in the lines available in the table.

Saving a table to data file

Only those values are saved to the data file that are positioned in cells that are available for editing. Values are saved irrespective of whether displaying of cells containing these values is enabled or disabled in the table.

We will describe how to write the table shown in Fig. 2.7.44 into a file.

In Fig. 2.7.44, a) you can see the table with cells containing coordinates that are not available for editing, while cells with variables' values are available for editing. Only variables' values will be saved to the data file.

In Fig. 2.7.44, b) you can see the table with cells containing coordinates' values and cells with variables' values that are both available for editing. Both coordinate values and variables' values will be saved to the data file. If displaying of columns with coordinates of points is disabled for a certain table, then, irrespective of this, values of points' coordinates will be saved in the data file.

2.7.7.4. Orientation of Array Instances

Array's instances can maintain their initial orientation or be rotated.

To select an instance construction option, activate the required switch in the **Orientation** group on the Property Bar:

- ▼ **Save initial orientation** (see Section 2.7.6.3.1 on p. 562),

- ▼ **Orient by radial direction** (see Section 2.7.7.4.1 on p. 575),

- ▼ **Orient by object** (see Section 2.7.6.3.3 on p. 564).

2.7.7.4.1. Construction of instances with turning in radial direction

If instances' positions are specified in cylindrical or spherical coordinates, you can orient instances in the radial direction. For this purpose, use the **Turn in radial direction** switch of the **Orientation** group on the Property Bar.

Once the switch is enabled, instances will be oriented in the following way:

- ▼ **Positions of instances are set in cylindrical coordinates**

Each instance is rotated around its base point so that it gets oriented with respect to a perpendicular from this point to Z axis, the same way as the base instance is oriented with respect to a perpendicular from its base point to Z axis (see Fig. 2.7.45, a).

- ▼ **Positions of instances are set in spherical coordinates**

Each instance is rotated around its base point so that it gets oriented with respect to a ray, going from the sphere's center to its base point the same way as the base instance is oriented with respect to its ray going from the sphere's center to its base point (see Fig. 2.7.45, b).

Fig. 2.7.45. Example of orienting array's instances in radial direction:
 a) positions are set in cylindrical coordinates;
 b) positions are set in spherical coordinates.

2.7.8. Mirror array

You can create copy of objects symmetrical to the them relative to the specified planar object.

Creation of mirror copy of assembly components is impossible.

Fig. 2.7.46. Mirror copying of objects:
 a) initial part (plane of symmetry for copying is shown nominally),
 b) the result of copying the base and support
 relative to midplane of rectangular projection

- ▼ The result of mirror-copying of an operation, plane, curve, point, auxiliary plane or surface is a new object being a mirror copy of the original object and of the same type as the original object.
- ▼ The result of mirror-copying of a body is a body possessing a symmetry plane, or new body that is a mirror copy of the existing one.

Mirror array for various object types is created differently. Therefore, control elements for creating an object's mirror copy depend on the type of the object: one set of control elements for a body or surface and another set is designed for operations, curves, or points.

The procedure of construction of a mirror array for operations, curves, and points is described in Section 2.7.8.1 on p. 576; creation of a mirror copy of a body or of a surface — see Section 2.7.8.2 on p. 577.

Note that each call of this command allows you to copy one of the following:

- ▼ either one or more operations,
- ▼ either one or several objects of the following types: a curve, point, auxiliary plane or axis,
- ▼ either one body,
- ▼ either one surface.

2.7.8.1. Creation of a mirror array of operations, curves, points, auxiliary planes, and axes

To create a mirror array of operations, curves, points, auxiliary planes or axes, you can do the following:

1. Call the **Mirror array** command.

Once the command has been called, the property bar will contain the **Choice of objects** tab (see Fig. 2.7.3 on p. 512).

2. Specify the **copied object**: operations, curves, points, auxiliary planes and axes.

For details about copied object selection, see Section 2.7.1.3.1 on p. 512.

The names of the selected objects will appear in the **List of Objects** toolbar.

Parameters and **Properties** tabs will appear on the Property bar.

You can also select objects for copying prior to calling the array creation command.

3. Enable the **Plane** switch and specify the **symmetry plane** in the Design Tree or mode window. The name of the selected object is displayed in a field beside the switch.

4. If required, you can also:

- ▼ Creating a **geometric array** with operations to be copied (see Section 2.7.1.3.5 on p. 515).
- ▼ Changing of array name and properties of surface of instances. Enable the **Properties** tab of the Property Bar.

5. Confirm array creation

Created array appears in the model window, while the icon attributable to its type is displayed in the Design Tree.

2.7.8.2. Creation of mirror copy of a body or a surface

To create a mirror copy of a body or a surface perform the following actions.

1. Call the **Mirror array** command.

Once the command has been called, the property bar will contain the **Choice of objects** tab (see Fig. 2.7.3 on p. 512).

2. In the **Type** group, enable the **Bodies or Surfaces** switch.

3. Specify the **copied object**: body or surface. The selected object is highlighted by a color.

For details about copied object selection, see Section 2.7.1.3.1 on p. 512.

Result of operation and **Properties** tabs will appear on the property bar.

You can also select an object for copying prior to calling the array creation command.

4. Select a **flat object** that will serve as the symmetry plane when copying the body. Such object can be any flat face and a projection or auxiliary plane.

After specifying a body (surface) and a plane of symmetry, there will be displayed the ghost of mirror copy of a body (surface).

5. Select the required **result of copying**, if a body is being copied. To do this, use the respective group of switches on the **Result of operation** bar (see Section 2.7.8.2.1 on p. 578).

6. Using switches of the **Mode** group, specify if the copied object should be maintained after execution of the command or not.

7. If required, you can also:

- ▼ Canceling the selection of all objects on the current tab of the Properties bar. To do this, click the **Reselect** button on the Advanced Control panel. Highlighting will be cleared off the previously selected object (objects), and you can select a new body.
- ▼ Changing of array name and properties of surface of instances. Enable the **Properties** tab of the Property Bar.

8. Confirm array creation

The model window will display a mirror copy of the selected body or surface, and the Design Tree will show the *Mirroring* icon.

2.7.8.2.1. Result of Mirror-Copying

- ▼ Activate the **Auto Determination** switch to have the operation results defined automatically. In this case, the construction is done as follows:

- ▼ if the mirror copy of the body does not intersect and does not have surfaces in contact with the source body, then the copy is constructed as a stand-alone body,
- ▼ if the mirror copy of the body intersects or has a common surface with the source body, then the bodies are merged into one.

The switch is active only during mirror array creation. When editing array in the first case, **New Body** switch is active on the Properties bar, in the second — **Union** switch.

- ▼ Activate the **New Body** switch to have the mirror copy as a separate body regardless of whether it intersects the source body, or not.

- ▼ Activate **Join** switch to merge the source body and its mirror copy.

When creating a new mirror copy, the result is defined automatically, i.e., by default, in the **Operation Result** group, the **Auto Determination** switch is active.

If the **Merge** switch was activated, whether manually or automatically, then a mirror copy of the body can be constructed only upon the condition that it would intersect or have a common surface with the source body. If this condition is not observed, the copy operation is marked as failing.

2.7.9. Array by Sample

You can to create an array of current assembly components located like instances of an existing array (**master array**).

You can use any type array, except for array by sample, as the master array.

Changed parameters of a master array are transferred to the array by sample and it gets rebuilt.

2.7.9.1. Creating a component array by sample

To create a component array by sample, complete the following steps.

1. Call the **Array by Sample** command.

After calling the command, the **Select Objects** tab on the Properties Toolbar will be activated.

Fig. 2.7.47. Object Selection tab

2. Select **copied components** to create the array. The names of the specified components will appear on the **List of Objects** bar.
3. Enable the **Options** tab.

- 3.1. Select the **master array**. To do this, activate the **Master Array** switch and specify the required object array in the Design Tree or in the model window.

The chosen master array will be color highlighted, and its name will be displayed near the switch.

The array ghost will be displayed.

- 3.1. Choose the **method of positioning the array's instances** with respect to the master array (see Section 2.7.9.2 on p. 579).
- 3.2. If the master array contains a nesting (i.e. its source object is another array), you can control the **number of instances** of the created array using the **Consider nesting** option.

If the option is enabled, the number of instances of the created array will be equal to a multiplication of the master array's instances number by the number of instances of the nested array. If the option is disabled, it is just the number of instances of the master array.

- 3.3. If the master array has deleted instances, you can control the **number of instances** of the created array using the **Consider deleted** options (see Section 2.7.1.3.6 on p. 516 for more information about deleting instances).

If the option is enabled, the created array will not contain instances with the same numbers as the numbers of deleted instances of the master array, otherwise, the instances will be contained in the created array.

All the changes will be reflected in the array ghost.

4. If necessary, change the array's name. To do this, use the controls of the **Properties** tab of the Property Bar.

5. Confirm array creation

Created array appears in the model window, while the icon attributable to its type is displayed in the Design Tree.

2.7.9.2. Array instances positioning

There are methods to position array's instances using a sample.

Method 1

Instances of the created array are positioned in space in accordance with the master array parameters.

In this case, data about its type and parameters are retrieved from the master array. This data is then used to create an array by a sample. For example, if an array by grid is used as the master array, data about array axes' objects and instance step value for each axis of the grid are retrieved. The result of the array creation will be the same as when creating a component array of the same type as the master array using the same parameters.

In Fig. 2.7.48, you can see example of creating an array by sample with parameters of the sample array. The array by grid is used as a sample. Its instances are shown in gray color. The copied object of each array is located in its lower left corner (highlighted by thick lines).

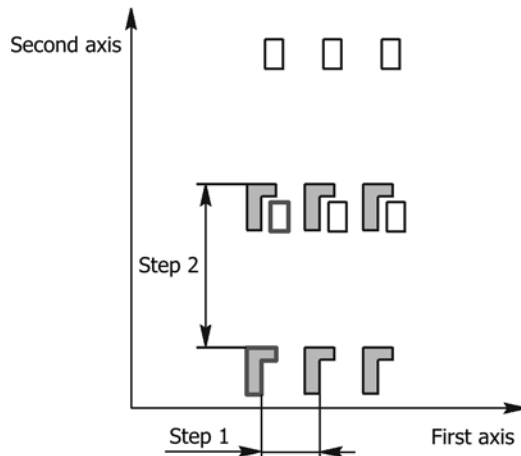

Fig. 2.7.48. Locating instances of the array by sample in accordance with parameters of the sample array

In order to create an array by sample using this method, enable the **By parameters of master array** switch in the **Method** group on the property bar.

Method 2

Instances of the array to be created are positioned against their respective instances of the master array in the same way as the object to be copied is positioned against its respective instance of the master array (base instance). By default, the nearest to the copied component instance is selected as a base instance in the master array. If several components are copied, then the instance closest to the component, that had been specified first, is selected as the base instance in the sample array. If necessary, you can select another base instance.

In order to create an array by sample using this method, do the following.

1. In the **Method** group on the Property Bar, enable the **Save position with respect to the instance of the sample array** switch.

The base instance of the master array, which is chosen by default, will be color highlighted. The array's ghost will be rebuilt — array's instances are positioned against their respective instances of the master array in the same way as the copied component is positioned against the base instance of the master array. The **Instance** control element will appear on the property bar.

2. In order to change the base instance, enable the **Instance** switch and specify the required instance of the master array in the Model Tree or window. The name of the selected instance is displayed in a field next to the switch. The array's ghost is being reconstructed.

Example of creating an array by sample using this method can be found in Fig. 2.7.49. The array by grid is used as a sample. Its instances are shown in light gray color. The copied component of the created array is shown in dark gray color. The base instance of the sample array is highlighted using thick lines.

Fig. 2.7.49. Locating of instances of array by sample keeping mutual disposition of the copied component and the base instance of the sample array:
 a) base instance of the sample array is selected by default;
 b) base instance of the sample array is specified by the user

2.7.10. Array of arbitrary objects

An option to create an array of arbitrary set of objects is available for all arrays with the exception of mirrored arrays and the arrays by sample. This variant makes it possible to create an array made of different types of objects within a single operation.

In order to create an array of arbitrary objects, enable the **Arbitrary** switch in the **Type** group after you call the command to create the required type of array (for example, array by grid). The following tabs will appear on the Properties bar: **Parameters**, **Instances**, **Operation result** and **Properties**.

All steps related to creation of an array of arbitrary objects are the same as steps related to creation of an array of the selected type of objects (for example, operations). The following are exceptions:

- ▼ object selection for copying (see Section 2.7.10.1 on p. 581),
- ▼ setting the array's application area (see Section 2.7.10.2 on p. 585).

Note the following features when exploding an array of arbitrary objects. Once an array is exploded, all objects of the array are transformed into objects that are absolutely the same as the source ones. Exceptions are sketches. They will no longer have any link to their base planes after explosion of the array. Such sketches are located in the model using the **Independent location** method (see Section 2.1.9.1 on p. 141 for more information about independent location).

2.7.10.1. Main principles of object selection

When creating an array of arbitrary objects, various types of objects can be selected for copying — operations, surfaces, curves, points, auxiliary planes, axes, sketches, coordinate systems and so on.

It is impossible to select bodies, components, previously created arrays and some operations (ribs, shell, sheet body, thicken and so on) for copying.

Objects to be copied are selected in the Design Tree. The names of the selected objects will appear in the **List of Objects** toolbar.

If the **Select intermediate elements** option is enabled, the set includes not only selected objects but also the objects located between them in the Design Tree. The inclusion of intermediary objects to the set does not depend on the Tree view you are using — sequence of construction or model structure. The first, the last, and intermediate objects are defined based on the sequence of model building. Objects that cannot be copied are not included in the set.

The following principles should be followed when selecting objects in order to correctly create an array.

1. When creating an array of arbitrary objects, the same constructions are created for each instance as for the object being copied. Therefore, in addition to the objects for copying, other objects required for their construction should be specified.

Examples:

▼ **Example 1.** A sketch was used to create the extrusion operation. When selecting objects for copying, both the extrusion operation and its sketch need to be specified. Each instance of the array will include the sketch copy and the extrusion operation copy. Otherwise, all instances of the array will be created in one sketch (source extrusion operation sketch) and will coincide with it.

▼ **Example 2.** 3D curves (segment and spline constructed by previously created points) are the axis and section of the revolution surface. When selecting objects for copying, the following objects should be specified: revolution surface, segment, spline and points to be used for spline construction. Each array instance will include copies of all of these objects.

If all objects, apart from the segment (revolution axis), are specified, all instances will be created around the revolution axis of the surface being copied.

If only the revolution surface, segment, and spline are specified, the spline of the copied surface will be used for construction of all instances, since spline copies in instances cannot be created if no source points are specified and so on.

2. In some cases, when creating an array, it is impossible to specify objects required for construction of the copied object (see Example 1) or it may be difficult to do so (see Example 2). In order to create array instances correctly, links between the copied object and its source objects should be removed. For this purpose, use the **Isolate objects** command described in Section 2.7.10.1.1 on p. 584. Once the command is applied, the *Copying* object is created. It should be specified together with copied object during array creation.

If a sketch is one of the source objects, note the following. The sketch is not included in the copy resulting from object isolation. The copied object maintains the link to the sketch. Therefore, the sketch needs to be specified when creating an array.

Examples:

▼ **Example 1.** A hole is built on the face resulting from sketch extrusion. Edges of the face define the hole's position. In order to create an array of holes, it is necessary to specify the hole for copying and its source extrusion operation. Each instance of the array will

contain both the hole and the extrusion operation. This will result in modified parameters of the body. To avoid this, you need to specify not the whole extrusion operation but only those of its objects that are absolutely required to create the hole, i.e. flat face on which the whole is located and edges defining its position. Apply the **Isolate objects** command to the hole. As a result, a copy will be created that includes only those objects that are required for the construction. The link between the hole and the extrusion operation is replaced by the link to the resulting copy. Now, when creating an array, you need to specify the copied hole and the copy of its source objects.

- ▼ **Example 2.** The surface is created by grid. In order to correctly create instances of this surface in an array, you need to specify both the surface and all of its points. This may take a long time. If you apply the **Isolate objects** command to a surface, you will need to specify only the copied surface and the *Copying* object resulting from its isolation when creating the array.
3. A sketch may be one of the source objects of the copied object. If the sketch is linked to a CS starting point (for example, by means of a controlling dimension), you will need to specify both the sketch and its CS for the array to be created correctly. CS specification may also be necessary if you need to specify coordinates of objects in instances when creating an array and handling it later.

If CS is specified, a copy of CS will be created for each instance with respect to which coordinates of objects included in the instance are determined. Values of the coordinates cannot be changed. Otherwise, no CS copies are created. Coordinates of objects included in the instances are determined relative to the source CS and have various values.

Examples:

- ▼ **Example 1.** A sketch was used to create the extrusion operation. It represents a circle with the center linked to the starting point of absolute CS by controlling dimension. When selecting objects for copying, the extrusion operation, its sketch, and its absolute CS need to be specified. Each array instance will include copies of all of these objects: extrusion operation, sketch with dimension, and CS. The dimension is entered between the center of the circle in the instance's sketch and the starting point of CS related to the instance. If CS is not specified during the array creation, its copies will not be created in instances. Circles in instances' sketches remain linked to the source CS. Therefore, copies of the circle coincide with the source circle, while copies of the extrusion operation coincide with the source operation.
- ▼ **Example 2.** Coordinates of the segment's ends are set in absolute CS. If a segment and absolute CS are specified during object selection, each array instance includes a copy of the segment and a copy of CS. Coordinates of the segment's ends in the instance are determined with respect to CS of the instance, therefore, values of the coordinates remain unchanged. If only a segment is specified during the array creation, copies of CS will not be created in instances. Coordinates of segment's ends in the instances are determined relative to the source CS and have various values.

Ghosts of CS copies are not displayed when creating an array of arbitrary objects.

2.7.10.1.1. Object isolation

In some cases, it is necessary to specify only some source objects of the object being copied (not all of them) in order to create an array correctly. For this purpose, object isolation is used. Examples of object isolation can be found in p. 2 of Section 2.7.10.1 on p. 581.

In order to isolate an object from source objects, select it in the Design Tree and call the following command: **Editor — Isolate objects** (if a body or surface is specified, the command is not available).

It is recommended to specify objects to be isolated when displaying the model construction sequence in the Tree.

Once the command is called, a copy of source objects of the object being isolated appears in the model. The copy is a model object that contains geometric objects without history. These objects are copies of the source geometric objects of the object being copied and are connected with them by associative links.

The copy is created in absolute coordinate system and is displayed in the model creation tree as the *Copying* object which is located in the Tree in front of the isolated object (if the display of model construction sequence is enabled). Objects included in the copy are displayed in the window of the model. If necessary, you can hide objects of the copy.

As a result of the command execution, links between the isolated object and its source objects are removed, while links between the isolated object and objects of the resulting copy are created.

The copy includes surfaces, faces, vertices, and edges (depending on the set of source objects).

For example, a surface results from rotation of a circle's arc about the edge of an extrusion element. When isolating a revolution surface, a copy is created which includes a circular arc (section of rotation) and an edge (axis of revolution). Operation of extrusion, which includes the edge, is not included in the copy.

If the source object is a sketch, the copy includes only those sketch objects that serve as an axis, path, guiding object. Other objects and the sketch itself are not included in the copy. The isolated object remains linked to the sketch.

When only a sketch and/or coordinate system are the source objects of an object to be isolated, the object cannot be isolated. Once the command is called, a message is displayed on the screen saying that the object has no replaceable links. Exceptions exist when a sketch contains an object which is an axis, path, or an object that defines building direction. In such cases, the object is isolated.

You can isolate several objects at once, if they are located one after each other in the Tree (if the model construction sequence display is enabled). For this purpose, select the required objects prior to calling the command using the <Shift> or <Ctrl> key.

It is impossible to isolate arrays, layout elements, and some operations, such as chamfer, fillet, slope, shell, boolean operation, change position, deduct components, copying, scaling, or sheet body operations.

2.7.10.2. Application area of the array of arbitrary objects

You can set the operation's application area when creating an array of arbitrary objects. For general information about application area of an operation, see Section 2.3.10.1 on p. 217.

In order to set an array's application area, use the **Operation result** tab in the Properties bar (Fig. 2.7.50).

Fig. 2.7.50. Setting an array's application area

This tab contains the **Application area** group of switches where the type of an operation's application area can be selected:

- ▼ Components and bodies – this operation is applied to components included in the model and to bodies created in the model,

- ▼ Components – this operation is applied only to components included in the model,

- ▼ Bodies – this operation is applied only to bodies created in the model.

Once the application area is selected, specify objects that make up the area. In order to specify bodies, elements in the **Operation result** tab are used. If components should be included in the application area, lick the **Components application area** button in the Special Control Panel. After this, the required controls will appear in the **Parameters** tab (see Section 2.3.10.4.1 on p. 222).

By default, application area is determined automatically. The **Auto determination** switch will be enabled both for bodies and components.

Auto determination means that the application area includes all objects (bodies, components, or both) intersected by the array's instances, except for objects that are hidden or excluded from calculation.

If an array's instance contains an operation of adding a material, it is joined with the body (if there is an intersection with a component, the instance is joined with the component's body). If there are no intersections, the instance is created as an independent body.

If an array's instance contains an operation that deletes material, an error will occur if there are no intersections in the model.

A specific feature of auto determination is formed when working with an array is that no list of objects making up the application area. If the model's composition is modified, the array application area will also be changed automatically.

Automatically determining an array's application area is preferable to manually specifying objects. The system will determine on its own which bodies and components each array's instance intersects with and includes the objects in the application area.

If bodies are specified manually, note that each specified body should intersect all instances of the array. Otherwise, an error will occur in the model.

In some cases, you need to manually select objects that make up the application area. For example, faces of two bodies adjoin each other. There is a hole, created in one of the bodies, the depth of which is defined by the **Through all** method. If the application area is determined automatically when creating an array, the resulting instances of holes will go through both bodies. To avoid this, the required body should be specified manually.

Manual specification of bodies is described in this section. For components, see Section 2.3.10.4.2 on p. 224.

In order to specify the required bodies, disable the **Auto determination** switch. The **Bodies** group will appear in the Properties bar. The following switches will be available there:

- ▼ **All bodies** makes it possible to include all bodies in the array's application area, except for hidden and excluded from calculation, regardless of whether they intersect with the edited feature or not.

- ▼ **Body Selection** allows the bodies that will be included in the current operation application area to be selected.

Upon activating the **Body selection** switch, the **List of Bodies** toolbar becomes available. It contains the list of bodies included in the operation application area and two buttons: **Select All** and **Delete**.

To add a body to the application area, select it in the Design Tree or in the model window.

The **Select All** button serves to include all bodies present in the model in the operation application area, including hidden bodies and bodies that do not intersect with the feature being edited.

The **Delete** button serves to exclude a body from the application area.

An array of holes with chamfers and fillets can be created correctly only within the body (component) that contains the objects to be copied. If an array's instance intersects another body (component), no chamfer (fillet) will be created. An error will occur in the model.

2.8. Auxiliary Items

2.8.1. Auxiliary Axes

If the existing edges in the model are not enough for object creation, you can create auxiliary axes.

You can find the auxiliary axis creation commands in the **Operations** menu, and the corresponding command calling buttons are grouped together on the **Auxiliary Geometry** toolbar.

Each auxiliary axis command will prompt you to specify the reference objects of the axis being created. For the purposes of construction, mostly **point**, **straight-line**, and **flat** model objects are used (they are listed in Table 2.1.7 on p. 131).

If objects were selected before calling the command, they will be used as the base objects for axis creation.

The created axis will be displayed in the Model window as a line segment. The Design Tree will show a special icon.

An axis-depicting line segment slightly protrudes beyond the extents of the objects selected to construct that axis. Sometimes, to better understand an axis location, you may want its rendering line segment to be longer (shorter) or be located at another part of the axis (straight line). You can change the size and position of this line segment by dragging its handles with the mouse (those appear when the axis is selected).

2.8.1.1. Axis through Two Vertices

To create an auxiliary axis going through two specified point objects, call the **Axis through Two Vertices** command.

Specify a pair of point objects that the axes will go through.

2.8.1.2. Axis on Plane Intersection

To create an auxiliary axis on the intersection line of two flat objects, call the **Axis on Plane Intersection** command.

Select two flat objects to create an axis at their intersection.

2.8.1.3. Axis through Edge

To create an auxiliary axis going through a straight-line object, use **Axis through Edge** command.

Specify the straight-line object that the new axis will go through.

2.8.1.4. Conical Surface Axis

Call the **Conical Surface Axis** command to create the auxiliary axis which is a revolution surface axis.

Specify the revolution surface which axis must be created.

2.8.1.5. Axis through Vertex along Object

You can create the auxiliary axis passing through a point object in the direction defined by a selected object or vector.

2.8.1.5.1. Objects Used for Construction

In order to create an axis, a point object and a guiding object are required.

Any of the objects listed in Table 2.8.1 or a vector created during the process of axis construction can be used as a guide object.

Tab. 2.8.1. Guide Objects

Object	Object-Defined Direction
Straight object	A straight line parallel or perpendicular to an object ^{***} .
Planar object	A straight line perpendicular to an object.
Flat curve:	A straight line perpendicular to a curve plane.
▼ arc,	
▼ circle,	
▼ a sketch line.	
3D curve [*]	A straight line directed along the tangent vector or vector of the principal normal ^{***} .
Revolution surfaces ^{**}	A straight line parallel or perpendicular to the revolution axis ^{***} .
Free-form surfaces [*]	A straight line perpendicular to an object at the indicated point.

* The point object must belong to a guide object.

** You can use sphere as a guide object in case the point object belongs to it. The direction defined by the sphere is a perpendicular line at the specified point.

*** Use the **Orientation** group of switches to select the required direction of the axis being created (see Section 2.8.1.5.2 on p. 588).

2.8.1.5.2. Axis creation

Call the **Axis through Vertex along Object** command to create the auxiliary axis passing through a vertex in the direction of a selected object.

If objects already exist in the model, specify them.

When you specify the point drawn by the **On Curve** (see Section 2.5.2.5 on p. 338) or **On Surface** (see Section 2.5.2.6 on p. 339) method, there will be automatically selected a guide object for the axis - a curve or surface on which the point is created. If necessary, you can select some other guiding object. For this, specify the required object in the model window.

Objects for constructing an axis can be also selected before calling the command.

If the model does not contain the required objects, you can create them without exiting the command.

- ▼ To create a point, press the **Point Creation** button on the Special Control Panel (see Section 2.5.2.11 on p. 346).

- ▼ To create a vector defining the axis direction, press the **Vector Drawing** button on the Special Control Panel (see Chapter 2.8.5 on p. 613).

Upon creating an object the system resumes the axis construction process.

Note that the object selected in the list is highlighted in the Design Tree. Change of the point parameters is only possible in the object editing mode rather than in the axis editing mode.

The ghost of the axis being created will be displayed once the objects are selected.

In some cases (see Table 2.8.1 on p. 588), you can select the direction of the axis being created: along or perpendicular to the guiding object. This is done by the **Orientation** group of switches.

- ▼ **Parallel to object,**

- ▼ **Perpendicular to object.**

Change of axis orientation is shown on the arc ghost in the model window.

To change objects used for axis construction, press the **Select Other** button on the Special Control Panel and re-select objects.

You can specify axis name and color in the **Properties** tab of the Property Bar.

To finalize the construction, click the **Create Object** button on the Special Control Panel.

2.8.2. Auxiliary Planes

If the coordinate planes and the flat facets, existing in the model, are not sufficient for object creation, you can create auxiliary planes.

You can find the auxiliary plane creation commands in the **Operations** menu, and the corresponding command calling buttons are grouped together on the **Auxiliary Geometry** toolbar.

Each auxiliary plane creation command will prompt you to specify the base objects for the plane and set its parameters in the corresponding fields on the Properties toolbar. For the purposes of construction, mostly **point**, **straight-line**, and **flat** model objects are used (they are listed in Table 2.1.7 on p. 131).

If objects were selected before calling the command, they will be used as the base objects for plane creation.

The plane with defined parameters is displayed on the screen as a ghost.

To lock the plane in the model, click the **Create Object** button on the Special Control panel.

All the commands to draw an auxiliary plane, except for the **Plane Tangent to Face at Point** command, have the auto-creation mode enabled by default. For more information on automatic and manual creation of objects refer to Section 1.4.2.10 on p. 93.

The created plane will be displayed in the Model window as a rectangle. The Design Tree will show a special icon.

A plane-depicting rectangle slightly protrudes beyond the extents of the objects, which were used as the base for constructing that plane. Sometimes, to better understand a plane location, you may want the plane-rendering rectangle to be larger (smaller) or be located at another part of the plane. You can change the size and position of this rectangle by dragging its handles with the mouse (those appear when the plane is selected).

2.8.2.1. Offset Plane

To create an auxiliary plane located at a certain distance from the selected planar object, call the **Offset Plane** command.

In the **Distance** field, enter the distance between the flat object and the plane being created.

Specify the flat object with respect to which the new plane's offset is assigned.

To specify the side of the existing plane or facet relative to which the new plane will be created, activate the **Forward Direction** or **Reverse Direction** switch in the **Offset Direction** group.

The offset distance and direction can be set using a handle (see Chapter 2.1.4.2.2 on p. 138).

2.8.2.2. Plane through Three Vertices

To create an auxiliary plane going through three point objects, call the **Plane through Three Vertices** command.

Specify the three points that the new plane will go through.

2.8.2.3. Plane at Angle to Another Plane

To create an auxiliary plane going through a straight-line object at an angle to an existing planar object, call the **Plane at Angle to Another Plane** command.

A straight object must be parallel to a planar object or lie on such an object.

Specify a flat object to which the new plane should be inclined at the given angle.

Specify the straight-line object that the plane will go through.

Input the angle between the planar object and the plane you are creating into the **Angle** field or select it in the list that drops down.

To specify the direction that the selected angle should be drawn in (relative to the planar object), activate the **Forward Direction** or **Reverse Direction** switch in the **Slope Direction** group.

The angle value and direction can be set using a handle (see Chapter 2.1.4.2.2 on p. 138).

2.8.2.4. Plane through Edge and Vertex

To create an auxiliary plane going through a straight-line object and a point object, call the **Plane through Edge and Vertex** command.

Specify the objects to construct the plane.

2.8.2.5. Plane through Plane Curve

Call the **Plane through Plane Curve** command to create an auxiliary plane passing through the specified plane curve.

The following may be used as a curve:

- ▼ a sketch line,
- ▼ spline or polyline with three vertices,
- ▼ arc,
- ▼ other flat curves: circular edge, etc.

Select the curve through which the new plane must go.

2.8.2.6. Plane through Vertex and Parallel to Another Plane

To create an auxiliary plane going through a point object and parallel to a planar object, call the **Plane through Vertex Parallel to Another Plane** command.

Select a point object and a planar object.

2.8.2.7. Plane through Vertex and Perpendicular to Edge

To create an auxiliary plane passing through the point object perpendicular to a straight object or vector, call the **Plane through Vertex and Perpendicular to Edge** command.

The point object does not have to necessarily belong to a curve.

If a point object and a straight object already exist in the model, specify them.

If the model does not contain the required objects, you can create them without exiting the command.

▼ To create a point, press the **Point Creation** button on the Special Control Panel (see Section 2.5.2.11 on p. 346).

▼ To create a vector, click the **Create Vector** button on the Special Control Panel (see Chapter 2.8.5 on p. 613).

Upon creating an object the system resumes the plane construction process.

Note that the object selected in the list is highlighted in the Design Tree. Change of the point parameters is only possible in the object editing mode rather than in the plane editing mode.

2.8.2.8. Normal Plane

To create an auxiliary plane normal to a revolution surface (except for a sphere), call the **Normal Plane** command.

Select a method to create a new plane using switches of the **Method** group on the Property Bar:

▼ **Autocreation** - to create the normal plane passing through the revolution surface axis and a point of this surface with zero values of U and V parameters (for face parametric representation refer to Section 2.5.1.3 on p. 328);

▼ **Parallel to the object**— construction of a normal plane which passes through the revolution surface axis in parallel to the specified coordinate plane or plane face.

Specify the objects to be constructed.

▼ If **Auto construction** is selected, specify the revolution surface.

▼ In case the **Parallel to Object** method is selected, specify a revolution surface and then the coordinate plane or flat face in relation to which the new plane will be located.

By default, the Object Auto Create option is enabled (see Section 1.4.2.10 on p. 93). This mode will automatically create a new plane (i.e. confirmation of the creation is not required) in the default position.

If you want to specify the new plane angle of rotation about the revolution surface axis, disable autocreation of objects (release the **Autocreation of Object** button on the Special Control Panel).

The angle will be calculated from the default position of the new plane.

Enter the required rotation angle value in the **Angle** field.

To specify the direction of drawing of the selected angle relative to the default position, activate the **Forward Direction** or **Reverse Direction** switch in the **Angle Direction** group.

The angle value and counting direction can be also set using a handle (see Chapter 2.1.4.2.2 on p. 138).

If you want to change the objects used to draw a plane, press the **Reselect** button on the Special Control Panel and then reselect the objects.

Confirm plane creation by pressing the **Create Object** button on the Special Control Panel.

2.8.2.9. Tangent Plane

To create an auxiliary plane tangential to a cylindrical or conical facet of the model, call the **Tangent Plane** command.

The initial position of the tangent plane is defined by the line of tangency. The line of tangency, in its turn, is determined as the intersection of said cylindrical or conical face and a flat object passing through its axis. The flat object must be created in advance. If necessary, the tangent plane can be rotated around the axis of the cylindrical or conical surface with respect to the initial position.

Indicate a cylindrical or conical face to which the new plane must be tangent, and then the flat object passing through its axis.

The tangent plane ghost appears on screen.

Enter the rotation angle of the tangent plane with respect to its initial position in the **Angle** field on the **Options** tab of the Properties bar. By default, the angle is equal to zero, and the new plane becomes perpendicular to the selected flat object.

The angle value can be set using a handle (handles are detailed in Chapter 2.1.4.2.2 on p. 138).

To specify the side (relative to the conical facet) on which the new plane will be created, activate the **Position 1** or **Position 2** switch in the **Plane Position** group.

2.8.2.10. Plane Tangent to Face at Point

Call the **Plane Tangent to Face at Point** command to create the auxiliary plane tangent to the specified face at the set point.

Select the face to make the new plane tangent to.

On the selected face, the ghost of the plane's theoretical surface will be displayed as a grid of the U and V isoparametric curves and the ghost of the plane being created as a rectangle (refer to Section 2.5.1.3 on p. 328 on the theoretical surface). By default, the new plane goes through the point of face specification.

Specify position of a new plane. This can be completed by the following methods:

- ▼ Specify the position of the point through which the plane should pass. The point position is determined by the offset along isoparametric curves U and V.

To specify the point offset, enter the respective values to the **Parameter U, %** and **Parameter V, %** fields.

- ▼ Associate the point (through which the plane will pass) with the existing point object (see Table 2.1.7 on p. 131). To do this, select the desired object in the Design Tree or in the model window. The **Point** button will be ticked, and the field next to the button will display the object name. This indicates the associative relation of the plane with the selected object. Due to this relation, the created plane will follow the object in case it changes its position.

If necessary, the relation can be disabled by pressing the **Point** button. The button will be unchecked, the field will be cleared.

In order to specify the plane position you can specify point objects both belonging and not belonging to the selected face, but being projected on this face. In this case, the projection determines the position of the plane being created.

If a model does not contain the required point object to construct a plane, you can create a point without exiting the command. To do this, press the **Point Creation** button on the Special Control Panel (see Section 2.5.2.11 on p. 346).

After the point is created, the system will proceed with creating the plane.

Note that the object selected in the list is highlighted in the Design Tree. Change of the point parameters is only possible in the object editing mode rather than in the plane editing mode.

2.8.2.11. Plane through Edge Parallel/Perpendicular to Another Edge

To create an auxiliary plane going through selected straight-line objects parallel or perpendicular to other straight-line objects, call the **Axis through Edge Parallel/Perpendicular to Another Edge** command.

Specify the straight-line object that the new plane will go through.

To select whether the plane will be **Parallel** or **Perpendicular** to the other straight-line object, activate the respective switch in the **Plane Position** group.

Specify the straight-line object the new plane will be parallel/perpendicular to.

2.8.2.12. Plane through Edge Parallel/Perpendicular to Face Command

To create an auxiliary plane through the selected straight-line objects, parallel or perpendicular to planar objects, call the **Plane through Edge Parallel/Perpendicular to Face** command.

Specify the straight-line object that the new plane will go through.

To select whether the plane will be **Parallel** or **Perpendicular** to the other object, activate the respective switch in the **Plane Position** group.

Select an object that the plane will be parallel/perpendicular to.

2.8.2.13. Median Plane

To create a bisecting plane of a dihedral angle, call the **Median Plane** command.

A dihedral angle is a space sector bounded by two half-planes with a common border line. These half-planes are called the **faces** of the dihedral angle, and the plane intersection line is called the **edge** of the dihedral angle. The angle between the facet intersection lines of a dihedral angle and a plane perpendicular to the edge of the dihedral angle is called the **linear angle** of the dihedral angle.

The **bisector plane** of a dihedral angle is a plane going through the edge of this angle and the linear angle bisector.

Fig. 2.8.1. Dihedral angle and its bisecting plane

A dihedral angle to construct a median plane can be defined by:

- ▼ faces; to do this, specify two flat objects,
- ▼ linear angle; to do this, select two straight objects,
- ▼ face and a side of a linear angle; to do this, select a flat and a straight objects.

To specify a median plane location relative to the selected objects, activate the corresponding switch on the **Settings** tab of the Properties toolbar:

- ▼ **Position 1:** a bisector plane will be created

- ▼ **Position 2:** a plane will be created perpendicular to the bisector plane and going through the edge of the dihedral angle.

In the special case when the specified objects are parallel, proceed with the construction in the following way (regardless of what position switch is active).

- ▼ If the objects are straight, then the median plane is constructed perpendicular to the plane going through them and at equal distances from each of them.
- ▼ If the objects are planar (flat), or if one is planar and another one is straight, then the median plane is constructed parallel to them at equal distances from each of them.

2.8.3. Coordinate systems

2.8.3.1. Absolute coordinate system

Every model has an absolute coordinate system and its corresponding planes. The names of coordinate axes and planes will appear in the Design Tree immediately after creating the new model file.

The absolute coordinate system of the model is shown in the middle of the window as three orthogonal lines in red, blue and green. All the three lines have a common origin coinciding with the origin of model coordinates, i.e. the point with coordinates 0, 0, 0.

The planes are represented by special symbols, i.e. the red, blue and green rectangles lying in their respective planes. By default the rectangles are positioned in such a way that their centers coincide with the origin of coordinates in order to visualize the spatial plane layout for the user.

In some cases the plane rectangle may need to be enlarged (reduced) or located at elsewhere on the plane to facilitate understanding of the plane position. You can change the size and position of this rectangle by dragging its handles with the mouse (those appear when the plane is selected).

The absolute coordinate system axes and planes cannot be removed from the part file. However, they can be renamed (see Section 2.1.2.5 on p. 111) as well as enabled or disabled in the model view window (see Section 2.14.1.1 on p. 781).

In the left bottom corner of the window document, you can see the model orientation control. It consists of three thick arrows — red, green and blue, indicating positive directions of the X-axis, Y-axis, and Z-axis respectively. This control allows you to change orientation of the model, e.g. by clicking the arrow or by rotating it. Working with the dialog is described in Section 2.1.3.3 on p. 124.

This feature rotates together with the mode, just like the symbol at the origin of coordinates; however, unlike the latter, it does not shift when shifting the model and cannot be disabled.

If necessary, you may create local coordinate systems in the model. For detailed information on creation and use of local coordinate systems see below.

2.8.3.2. Local Coordinate Systems

Sometimes, an absolute coordinate system fails to provide an adequate description of a part segment or it can be used only upon performing additional calculations. Usually this happens when constructing part segments which are rotated relative to the absolute coordinate system.

In these cases, to simplify work you can start by creating a local coordinate system (LCS), with its origin and axes placed as required, where you can create objects afterwards. For example, if you want to produce a polyline with its segments perpendicular to each other, but at an angle to the absolute coordinate system axes, you can first create LCS with its axes parallel to the segments of the future polyline and its origin coinciding with the polyline's first vertex.

LCS may be also used for positioning of base parts, imported surfaces, assembly components. LCS creation is described in Sections 2.8.3.5–2.8.3.7, creation of objects using LCS — in Section 2.8.3.4.

You can build several LCSs in a model, with the possibility of switching between them making currently required LCS as **the current LCS** (see Section 2.8.3.3). The coordinate system which was the current one at the moment of object creation becomes the coordinate system of this object.

Objects are constantly connected with their coordinate systems. This makes it possible to quickly change the position of the part segment by changing the position of its coordinate system.

Objects can be transferred from one coordinate system to another (See Section 2.8.3.4.2).

All LCSs available in a model are displayed in the Design Tree, similar to other objects. If model structure display is enabled in the Tree (See Section 2.1.2.2 on p. 106), then LCSs are in the *Coordinate systems* Section.

In the model window, you can disable display of individual LCSs or all coordinate systems at once, and you can also exclude LCS from calculation using the same techniques as those used for other objects (see Sections 2.14.1.1 on p. 781 and 2.14.1.2 on p. 783).

If the LCS is excluded from calculation, all objects built in it will be also excluded, and in case of removal — removed.

Standard drawing views of a model are defined based on its absolute coordinate system.

2.8.3.3. Current coordinate system. Selection of the current coordinate system

At any time, only one coordinate system of a model can be the current system.

The letter T in parentheses is displayed before the name of the current coordinate system in the Design Tree (see Fig. 2.8.2).

Current LCS is displayed in the model window in colors preset for it's elements, whereas all the rest LCSs - in gray color. The absolute coordinate system of a model is colored independently of whether it is the current one or not.

To assign a local or absolute coordinate system the “Current” status, do the following:

1. Call the **Editor— Select Current CS** command. The coordinate system which is the current one at the moment shall be highlighted in the model window.
2. Specify the coordinate system in the Design Tree that should be the current one. You can also set the origin of this system in the model window.

To assign and unassign the Current status, you can use the **Current CS** command in the context menu of the coordinate system in the Design Tree:

- ▼ If the command is ticked, then the coordinate system is already the current one; upon calling the command it shall not be the current system any longer; instead, the absolute coordinate system shall become the current one;
- ▼ If the command is not ticked, it means that the coordinate system is not the current one; upon calling the command it shall become the current coordinate system.

If you enabled the **When creating LCS, Assign it As the Current CS** option when customizing the LCS (See Section 9.1.11.9 on p. 1734), then every new LCS shall automatically gain the “Current” status.

2.8.3.4. Using LCS

- ▼ LCS may be used as the object coordinate system (See Section 2.8.3.4.1) for the objects, the position and/or orientation of which are defined in relation to the coordinate system (and not in relation to the other objects of the model). If LCS is the object coordinate system, this object can be moved and rotated in the absolute coordinate system by changing the LCS position. To make an object independent from LCS, transfer it to the absolute coordinate system of the

model (see Section 2.8.3.4.2 on p. 600).

- ▼ You can use the LCS elements, such as the origin, coordinate planes and axes, for construction of a model similar to the use of other point, planar and linear objects.
- ▼ The *Coincidence* mating imposed on two LCSs makes them (and, hence, the components that contain them) immobile with respect to each other.

2.8.3.4.1. Object coordinate system

Object coordinate system is a coordinate system with respect to which object position and/or orientation are defined.

The list of objects that use coordinate system is presented in Table 2.8.2.

Tab. 2.8.2. Objects that use coordinate system

Object	Object parameters that depend on coordinate system
Point	<ul style="list-style-type: none"> ▼ Coordinates of a point in case of using the By Coordinates (XYZ), By Cylinder (RAZ), By Sphere (RAB) techniques ▼ Axes orientation to define coordinates of a point with respect to the reference point when using the Transfer technique.
Polyline, spline	<ul style="list-style-type: none"> ▼ Vertex coordinates when using the By Points technique ▼ Axes orientation when using the By X Axis, By Y Axis, By Z Axis techniques
LCS*	<ul style="list-style-type: none"> ▼ Coordinates of the origin (LCS creation by the basic technique) ▼ Euler angles (LCS creation by supplementary techniques)
Circular arc, segment	Coordinates of points
Sketch	<ul style="list-style-type: none"> ▼ Default position of the origin ** ▼ Default axes orientation **
Imported Surface	Position and orientation.
A group of points by a curve, by a surface	Point coordinates (available after ungrouping).
Group of points from a file	Point positions. Points are created in the current coordinate system according to the coordinates saved to file.
A surface by a point grid, by a point layer	Coordinates of points (created using the Point Creation command) or position of points (retrieved from file).
Curve by law	Curve position. The curve is built in the current coordinate system in accordance with the predefined functions.

Tab. 2.8.2. Objects that use coordinate system

Object	Object parameters that depend on coordinate system
Body or surface position change operation	Body or surface position. A body or surface is linked to a hypothetical coordinate system, the origin of which coincides with the current coordinate system; in order to define the position of the body/surface, the required position of the hypothetical coordinate system is defined.
Pattern by Table	Pattern instances position. The array is built in the current coordinate system using points with coordinates saved in file.
Area	Point coordinates of the box (when creating zones by coordinates) or orientation of the dimensional box of the objects (when creating a zone by dimensions of the objects).

* LCS settings can be defined in some other LCS if the system customization (see Section 9.1.11.9 on p. 1734) has been performed with the **Create LCS in Absolute CS only** option disabled.

** When editing a model afterwards, the position and orientation of the sketch coordinate system can be changed using the **Place Sketch** command (see Section 2.14.3.1.2 on p. 787).

Spirals and round holes are connected with the coordinate system indirectly: the coordinate system is used by the sketch which is automatically created when constructing a spiral or a hole.

At first, a coordinate system of an object is the system which was the current coordinate system at the moment of object creation. How to make a coordinate system the current one, see Section 2.8.3.3 on p. 597.

If required, you can transfer an object from its coordinate system to another system (see Section 2.8.3.4.2).

Use of LCS axis, plane or origin of coordinates when creating an object (for example, creating a sketch on XOY plane of the local coordinate system) does not make LCS the coordinate system of this object.

If an object is constructed in the local coordinate system instead of the absolute coordinate system, the icon of this object in the Design Tree is marked with LCS sign which is a mini LCS icon (Fig. 2.8.2).

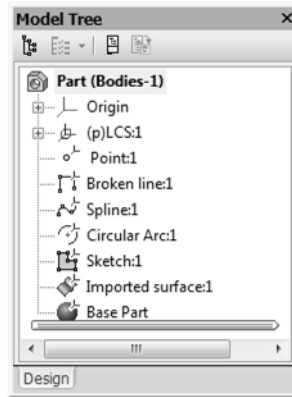

Fig. 2.8.2. Display of objects built in the LCS in the Design tree

During creation or editing of this object, the name of its coordinate system is displayed on the **Properties** tab of the Properties toolbar.

The **CS** field is also displayed on the Properties toolbar when viewing object's properties (Fig.2.8.3). To view the properties, call the **Properties** command from the context menu of the object icon in the Design Tree.

Fig. 2.8.3. **CS** field on the Property Bar

2.8.3.4.2. Replacing the object coordinate system

Any of the objects listed in Table 2.8.2 can be transferred from its coordinate system to another coordinate system.

Object transfer is only possible using the coordinate systems located above the object in the Design Tree.

To replace the object coordinate system, call the **Editor — Transfer to CS** command.

Upon calling the command you shall see, on the Properties toolbar, the controls for transferring objects to another coordinate system.

Specify the objects in the Design Tree, the coordinate system of which is required to be changed.

The names of the selected objects shall appear in the **List of Objects** toolbar (Fig.2.8.4). The object name is followed by the name of its coordinate system in parentheses.

Objects to be moved to another coordinate system can be also highlighted prior to the command calling.

Fig. 2.8.4. Controls that allow you to transfer objects to another coordinate system

To delete any object from the list, highlight it and press the **Delete** button, located above the list.

Select the coordinate system to move objects to, by specifying it's name in the **CS** list.

The **Save position** option serves to specify if an object position should be saved in the absolute coordinate system of a model after transferring to another coordinate system.

- ▼ If the option is enabled, object parameters shall be recalculated with respect to the new coordinate system so that the object position in the model shall not change.
- ▼ If the option is disabled, object parameters shall be saved whereas the object position in the model shall change.

Having finished the setting, press the **Create object** button on the Special Control Panel to transfer objects to the selected coordinate system.

Features of object transfer from one coordinate system to another

- ▼ Parameters of some objects (polyline, base part, etc.) are not recalculated, i.e. they change their position regardless of the **Save Position** option status. Such objects are marked with a lock icon in the list.
- ▼ Elements of an object can have associative relation with other objects. In the result of replacement of the object coordinate system, the position of related elements do not change irrespective of the **Save position** option status. For example, there is an arc of circle built by three points, with two of them being defined by their coordinates and the third one coinciding with the vertex. Upon transferring this arc to another coordinate system with the **Save Position** option disabled, the points defined by coordinates shall move, whereas the point related to the vertex shall remain in it's place.
- ▼ LCSs can be transferred from one coordinate system to another only if during the LCS setting (see Section9.1.11.9 on p. 1734) the **Create LCS Only in Absolute CS** option is disabled.

2.8.3.5. LCS creation. General Information

The main settings of LCS that define it's location in space are position and orientation.

- ▼ **Position** is a setting defining the LCS center location.
- ▼ **Orientation** is a setting defining direction of LCS axes.

LCS settings are defined with respect to it's own coordinate system. Own coordinate system of LCS is the absolute coordinate system of the model or the current coordinate system (it depends on the LCS setting, see Section9.1.11.9 on p. 1734).

To start LCS creation, call the **LCS** command. The command calling button can be found on the **Auxiliary Geometry** toolbar.

Upon calling this command, the process of LCS creation by the basic technique is started. See detailed description of this process in Section 2.8.3.6.

There are also additional techniques available for LCS creation. To access them, press the **Additional Methods** button on the Special Control Panel. The process of LCS creation by additional methods shall start. See detailed description of this process in Section 2.8.3.7.

Using either the basic or additional methods, define position and orientation of the LCS being created. All updates shall be displayed on the LCS ghost in the model window.

An LCS name may be changed in the **Properties** tab of the Property bar. The name of the own coordinate system for the LCS being created is also displayed there.

Having obtained the required LCS location, fix it by pressing the **Create object** button of the Special Control Panel.

The created LCS shall be displayed in the model window, and its icon shall appear in the Design Tree.

If LCS setup (See Section 9.1.11.9 on p. 1734) is performed with the **When creating LCS, Assign it As the Current CS** option enabled, the created LCS shall become the current one.

2.8.3.6. Basic method of LCS creation

This method of LCS creation is available directly upon calling the **LCS** command. Property toolbar contains controls shown in Figure 2.8.5.

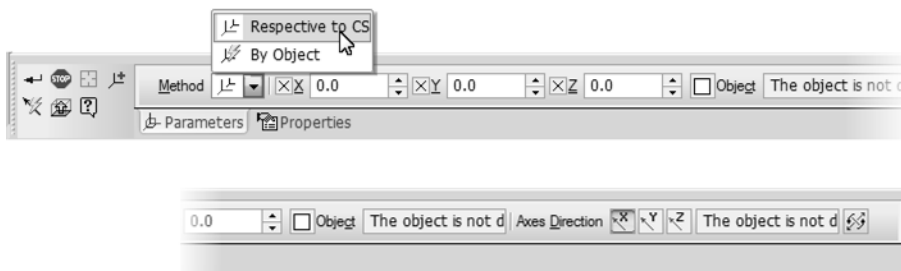

Fig. 2.8.5. Property toolbar if LCS is created by the basic method

A ghost of the LCS being created shall be displayed on the screen. By default, the new LCS coincides with its own coordinate system.

You can specify position and orientation of the LCS being created:

- ▼ with respect to the coordinate system (See Section 2.8.3.6.1),
- ▼ with respect to some object if its properties provide for unique determination of the LCS settings (See Section 2.8.3.6.2).

To select a method of determination of the LCS position and orientation, open the **Method** dropdown list and specify the required line in it (Fig. 2.8.5).

2.8.3.6.1. Creation of LCS with respect to a coordinate system

When creating LCS with respect to a coordinate system, a ghost shown in Figure 2.8.6 shall be displayed.

Fig. 2.8.6. LCS ghost

LCS position

To define the LCS position, enter the coordinates of its point of origin in **X**, **Y**, **Z** fields or specify a point object in the model window. Point objects used for the LCS creation are the same as those used for the point creation (see Section 2.5.2.1.1 on p. 335). The LCS ghost shall move so as to have its origin coinciding with the specified point.

To change the selected point object, press the **Define Again** button on the Special Control Panel and specify the required object in the model window.

If a point object is defined to specify the LCS position, the LCS origin shall have an associative connection with this object. Note that:

- ▼ **X**, **Y**, **Z** fields contain the object coordinates and cannot be edited,
- ▼ the **Object** button is ticked, whereas the **Object** field shows the object name.

Due to the associative connection, the LCS origin shall follow the object in case its position is changed.

To cancel the associative relation with the point object, click the **Object** button. The tick on the button will disappear.

To restore the associative relation of the point with the point object, specify the required object again.

You can move LCS in the model window with the mouse using the ghost's handles. Use the points which are displayed in the form of squares to specify the LCS position.

- ▼ The LCS origin point can be moved at random. The LCS ghost shall follow the handle. As this takes place, the current coordinates of the point are displayed in **X**, **Y**, **Z** fields; if one or two coordinates are fixed, displacement occurs in a plane or along an axis.
- ▼ End points of the axes can be moved in the direction of these axes. The LCS ghost will move in the same direction. The current coordinates of the LCS origin are displayed in **X**, **Y**, **Z** fields.

LCS orientation

To define the LCS orientation, enable the switch corresponding to the axis, the direction of which you want to define, in the **Axis Directions** group.

- ▼ X Axis,

▼ Y Axis,

▼ Z Axis.

The selected axis shall be highlighted on the ghost in the model window.

The axis, the direction of which should be changed, may be pointed with the mouse in the model window. For this, move the cursor to the required axis and left click the mouse when the *Guide Object of Axis* line will appear beside the cursor.

Select a guide object. When creating LCS, the same linear and planar guide objects are used as those involved in point creation (See Section 2.5.2.1.1 on p. 335).

Moreover, the guide object may be represented by a vector. In this case direction of the selected axis will coincide with the vector direction. You can create this vector using the **Vector Drawing** command (see Chapter 2.8.5 on p. 613).

The name of the selected object is displayed in the **Axis Guide Object**. The LCS axis shall have an associative connection with this object. If the vector defines the axis direction, message "Vector" appears in the field.

Direction can be set for two axes only. The third axis will be automatically directed in such a way so as to form a right-hand system with the first two.

After you select a guide object or draw a vector for the first axis, the LCS will rotate so that this axis matches the direction specified by this object or vector.

The guide object direction for the second axis can be non-perpendicular to the first axis. In this case the direction of the second axis is defined as a projection of the direction, defined by the object, on the plane perpendicular to the first axis.

If the object is either parallel to or on the same axis with the first axis, such object can not be used as a guide for the second axis.

If the vector is collinear to the first axis, such vector can not be used as a guiding object for the second axis. The message will pop up if an error take place.

If required, you can set the opposite direction for any of the LCS axes. This is done by enabling, first, the radio button corresponding to the axis in the **Axes Directions** group, then the **Reverse Axis** radio button.

You can use the mouse to reverse LCS axes. For this, having the `<Ctrl>` key pressed, left click the mouse on the characteristic point at the end of the required axis.

You can arbitrarily rotate the LCS with the mouse in the model window by moving the ghost handles. The points displayed as circles serve to define the LCS orientation. Each handle corresponds to one of the LCS planes and allows rotating the LCS around the axis perpendicular to this plane.

The axis of the LCS rotation remains immobile, whereas the other two axes are displaced. If any of them was associated with the object, this associative connection is removed.

2.8.3.6.2. LCS creation with respect to object

Initially, there is no LCS ghost in the model window when creating LCS with respect to object. It appears only upon selection of the object that defines the LCS position. The object with respect to which an LCS is created, uniquely defines its position and orientation (Table 2.8.3).

Tab. 2.8.3. Objects for LCS creation

Object	LCS settings defined by the object	
	Ref.No.	Orientation
Sketch	The sketch coordinate system origin	X coincides with the X axis of the sketch coordinate system, Y coincides with the Y axis of the sketch coordinate system Z auto determination
Intermediate vertex of a polyline	Polyline vertex	X parallel to the previous segment of a polyline, Y parallel to a projection of the following polyline segment on the plane perpendicular to the X axis, Z auto determination
A point created by the method On curve*	Point	X parallel to the tangent to the curve in the point, Y parallel to the main normal to the curve in the point Z auto determination
A point created by the method On surface or Projection	Point	X parallel to the tangent in the U direction ^{**} , Y: parallel to the tangent in the V direction ^{**} , Z auto determination
Circular Arc or Elliptical Arc (curve, contour in a sketch or an edge)	Arc center	X directed to the start vertex of the arc, Y auto determination, Z perpendicular to the arc's plane
Coordinate system	CS origin	X coincides with the X axis of the coordinate system Y coincides with the Y axis of the coordinate system Z coincides with the Z axis of the coordinate system
Body ^{***}	Center of Gravity	X coincides with the Ox axis of inertia, Y coincides with the Oy axis of inertia, Z coincides with the Oz axis of inertia.
Planar face	Center of Gravity of a face ^{****}	X coincides with the X axis of the face coordinate system, Y coincides with the Y axis of the face coordinate system, Z auto determination

- * It is impossible to use a point created on a linear curve for LCS creation.
- ** U and V directions are shown on the screen, for example, during the point construction by the **On surface** method.
- *** Bodies which have no axes of inertia (for example, a sphere) cannot be used. If the selected body has one axis of inertia (for example, a cylinder), the LCS's Z axis coincides with it.
- **** You can choose a variant of a faces' mass center position. For this purpose, the **Only outer contour** option on the Property bar is used (see below).

To define an object for LCS creation, specify it in the Design Tree or in the model window. The name of the selected object shall be displayed in the **Object** field. LCS is associated with this object.

The **Only outer contour** option controls the position of a flat face mass center which defines the LCS position. If the option is enabled, only the outer face's contour will be taken into account during the face's mass center calculation. If the option is disabled, the face's mass center is calculated taking account of the face's internal contours.

Variants of the flat face's mass center position can be seen in the figure; the mass center is marked by a circle.

Fig. 2.8.7. Variants of a flat face's mass center positioning:
 a) if the **Only outer contour** option is enabled,
 b) if the **Only outer contour** option is disabled

2.8.3.7. Additional methods of LCS creation

To switch to additional methods of LCS creation, press the **Additional Methods** button on the Special Control Toolbar after calling the **LCS** command.

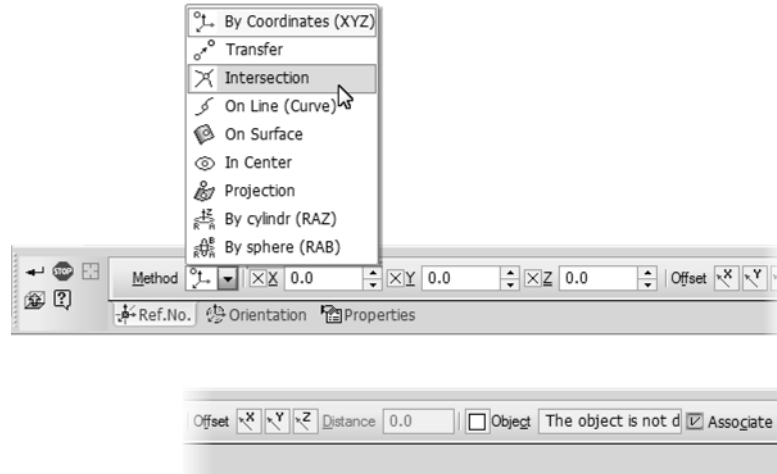

This makes the **Settings** tab on the Properties toolbar to be replaced with two tabs: **Position** and **Orientation**. They serve to specify LCS positions and orientations using various techniques. See detailed description of these tabs in sections 2.8.3.7.1 and 2.8.3.7.2.

2.8.3.7.1. LCS position

Use the **Position** tab of the Property toolbar (Fig. 2.8.8) to define the LCS position.

Controls of the **Position** tab allow you to define the position of the LCS origin using the methods available in the **Point** command (see Section 2.5.2.1 on p. 334).

Fig. 2.8.8. Position **Tab**

The only difference of the LCS positioning process from the point creation process is the presence of additional controls in the **By coordinates** method. These controls are the **Offset** group of switches and the **Distance** field. They provide for moving the LCS along its own axes.

To select an axis along which you want to displace the LCS, enable the relevant switch in the **Offset** group, then enter an offset distance in the **Distance** field. The positive value means an offset in the axis direction, the negative value – in the opposite direction.

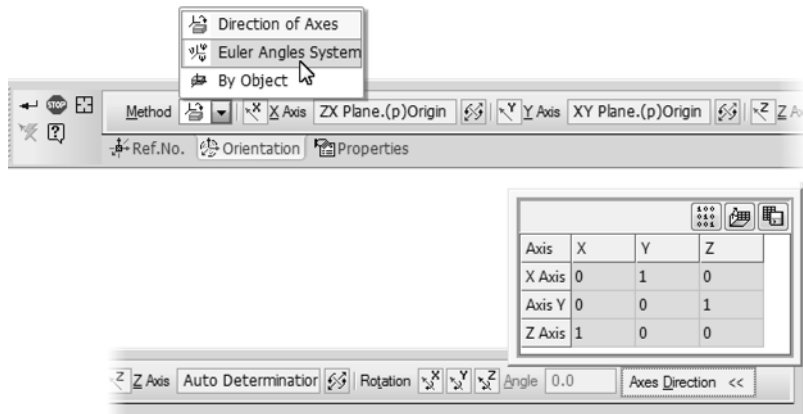

The **Distance** field is zeroed after every input, and a new LCS offset is counted from its current position.

For any changes of the LCS position its orientation remains constant.

2.8.3.7.2. LCS orientation

To define the LCS orientation, use the **Orientation** tab of the Properties toolbar (Fig.2.8.9).

Fig. 2.8.9. **Orientation** tab

Three methods of the LCS orientation are available:

- ▼ defining guide objects or drawing vectors for axes and, if required, rotating the LCS around its own axes,
- ▼ LCS rotation with respect to its own coordinate system by setting Euler angles,
- ▼ with respect to some object if its properties provide for unique determination of the LCS orientation.

To select the LCS orientation method, open the **Method** list and select the required line in it (Fig.2.8.9). See below detailed description of the orientation methods.

For any changes of the LCS orientation, its position remains constant.

When defining the LCS orientation using the **Axes Directions** and **Euler Angle System** methods, the **Axes Directions** toolbar is available on the Property toolbar. It contains a table of coordinates of unit vectors, which are co-directed with the LCS axes. These coordinates are defined in the LCS's own coordinate system. Values in the table shall change if the LCS orientation changes. It is impossible to manually edit coordinates of the unit vectors. The **Axes Directions** toolbar contains three buttons.

- ▼ **Initial Orientation** Allows cancel all changes of the LCS orientation. After this button is pressed LCS axes will become codirectional with the respective axes of its own CS.

- ▼ **Read from File.** Allows orienting the LCS on three single vectors, the coordinates of which are written in a file. After clicking this button a dialog will be displayed to specify the file containing coordinates of the vectors, then click the **Open** button. Values in the table will change, and the LCS ghost will turn in the model window. All previously made LCS orientation settings (selection of objects or input of angle values) will be cancelled.

The relation of LCS with the file of single vector coordinates will not be generated.

- ▼ **Save into File.** Allows writing the current coordinates of single vectors in a file. After clicking this button a dialog will be displayed to specify the folder to place the file and its name.

Files of single vector coordinates have text format. You can view, edit or create such file using any text editor. See detailed description of the file of unit vectors coordinates in Section 2.8.3.7.3 on p. 610.

Axes directions

To select an LCS axis to specify its direction, enable the required switch (see Fig.2.8.9):

- ▼ **Guide object for X axis,**
- ▼ **Guide object for Y axis,**
- ▼ **Guide object for Z axis.**

Specify a guide object in the model window or draw a vector that specifies the direction of the selected axis (on vector, refer to Chapter 2.8.5 on p. 613).

The name of the selected object is displayed in the field next to the selected switch. If the vector defines the axis direction, message “Vector” appears in the field.

To the right from the guide object name, there is a button to reverse the axis.

To rotate the LCS around any of its own axes, enable the required radio button in the **Rotation** group, then enter a rotation angle around the selected axis in the **Angle** field.

The **Angle** field is zeroed after every input, and a new LCS rotation angle is counted from its current position.

LCS orientation by the **Axes Directions** method is essentially the same as the **With Respect to CS** method. See description of this process in Section *LCS orientation* on p. 603. You can refer to this section for more information about LCS orientation by defining guide objects and rotation around own axes.

Euler angles system

To define Euler angles defining the position of LCS with respect to its own CS, enter required values in the **Nutation Angle**, **Precession angle** and **Rotation angle** fields (Fig.2.8.10).

Fig. 2.8.10. Property toolbar for entering Euler angles

When using LCS orientation by the **Euler angles system**, you can reverse any of the axes. For this purpose, having the **<Ctrl>** key pressed, left-click the mouse on the handle at the end of the required axis in the model window. Positions of the LCS ghost will change on the screen, and the values corresponding to the new position will be displayed at angle fields.

By Object

To orient the LCS with respect to some object, the properties of the specified object must provide for unique determination of the LCS orientation.

The list of possible objects is shown in Table 2.8.3 on p. 605. Directions of LCS axes defined by these objects are shown in the *Orientation* column of the same table.

Define the object to orient the LCS in the Design Tree or in the model window. The position of the LCS ghost in the model window changes, the name of the selected object is displayed in the **Object** field. LCS is associated with this object.

2.8.3.7.3. File of unit vectors coordinates

The file of unit vectors coordinates is used to define the LCS orientation. The file has text format (*.txt).

The file of unit vectors coordinates should contain three lines of coordinates: When interpreting the file of unit vectors coordinates it is assumed that:

- ▼ the first line contains coordinates of X vector, the second— Y vector, the third — Z vector;
- ▼ the first number in the line is the vector coordinate along the X axis, the second — along the Y axis, the third — along the Z axis.

All lines located below the lines of coordinates are assumed to be comments and they are not taken into account.

The file can contain coordinates of mutually perpendicular, but non-unit vectors. In this case, LCS is oriented with respect to the specified vectors, and the table shows the values of the respective unit vectors.

Conventions concerning coordinate lines:

- ▼ one line contains coordinates of one vector;
- ▼ delimiters of coordinates in a line are spaces,
- ▼ lines of coordinates are at the beginning of the file and go one after another,
- ▼ at the beginning of the line (before the first coordinate) there can be spaces, at the end of the line (after the last coordinate) — an arbitrary comment.

If the contents of the file indicated for reading vector coordinates fails to meet the above-mentioned requirements, or if the vectors described in it are not mutually perpendicular, a message on the impossibility to retrieve data shall be displayed. The current LCS orientation shall not change in this case.

2.8.3.8. LCS variables

Upon LCS creation, variables of this LCS are automatically generated in the model.

Work with variables and expressions is described in detail in Section 7.1 on p. 1569.

There are twelve informative variables among the LCS variables. They correspond to coordinates of the LCS origin and coordinates of unit vectors. These variables are always created.

Availability and contents of other variables is defined by the LCS creation method:

- ▼ For LCS created by the basic technique, variables of the point of coordinates origin will be generated,
- ▼ For LCS created by additional techniques:

- ▼ if the LCS position was defined by the method of point creation **By Coordinates**, **Transfer**, **On Curve** or **On Surface**, the variables corresponding to the settings specific for these techniques are created for LCS (see Table 2.5.2 on p. 345).
- ▼ If the LCS orientation was defined using Euler angles, the variables corresponding to nutation, precession and rotation angles are created for LCS.

If the LCS's own coordinate system is the local system and not the absolute coordinate system, then only informative variables of the coordinate point of origin and those of unit vectors are created for the LCS.

Values of all LCS's variables are defined in the absolute coordinate system.

Figure 2.8.11 shows variables of LCS built by additional methods, with the LCS position defined by creation of a point **On curve** and orientation — by entering Euler angles.

Name	Expression	Value	Parameter
Part (Bodies-0)			
Origin			
(p)LCS:7			
v30		0.0	Exclude from Calculation
v31		10.0	Start point. X
v32		325.0	Start point. Y
v33		55.0	Start point. Z
v34		10.0	X coordinate
v35		325.0	Y coordinate
v36		55.0	Z Coordinate
X Axis			
v41		0.0	X Axis. X
v42		0.8290	X Axis. Y
v43		0.5592	X Axis. Z
Y Axis			
v45		0.0	Y Axis. X
v46		0.5592	Y Axis. Y
v47		-0.8290	Y Axis. Z
Z Axis			
v49		-1.0	Z Axis. X
v50		0.0	Z Axis. Y
v51		0.0	Z Axis. Z

Fig. 2.8.11. LCS variables

2.8.3.9. LCS deletion

The LCS is deleted in a conventional way using the **Delete** command or the *<Delete>* key (see Section 2.14.3.8 on p. 797).

Please note that removing LCS you also remove the objects that have been built in this LCS. They are derivative objects with respect to LCS being deleted. These objects are listed in the warning dialog (displayed prior to deletion) along with other derivative objects of the LCS being deleted.

If the current LCS is deleted, then the absolute coordinate system shall become the current one.

2.8.3.10. Coordinate system setup

You can make the following settings of a model's coordinate system:

- ▼ for an absolute coordinate system — set names and color of coordinate planes, axes, and origin designations (see Section 9.2.7.5.5 on p. 1860),
- ▼ for local coordinate systems — set names and color of coordinate planes, axes, and origin designations (see Section 9.2.7.5.6 on p. 1860), as well as choose default methods of working with local coordinate systems (see Section 9.1.11.9 on p. 1734).

2.8.4. Control and Connection Points

Control and connection points are special objects used to design pipelines, bundles, etc. Such systems are created using specialized KOMPAS-3D applications (libraries).

Control and connection points are generated in those parts and assembly units that are intended for installation in pipelines, bundles, etc with the means of libraries. Control points provide arrangement of parts and assembly units along the system path, while connection points provide their coupling with each other and with path components. Arrangement and coupling of models is made using couplings.

Control and connection points are created using the **Control Point** and **Connection Point** commands respectively.

Fig. 2.8.12. Control and connection points

Despite the fact that control and connection points are special objects used by the libraries, you can use them, for example, to mark and designate directions inside models. Control and connection points, as well as the axis (axes) of connection point can be involved in mates just as usual point and linear objects.

2.8.5. Vector

Sometimes you may need to create a vector in space while constructing some object. To do this, the **Vector construction** command is used. In order to call this command, click the **Create Vector** button on the Advanced control panel. The system will switch to creating a vector.

You can draw a vector in space by the following methods:

- ▼ **By two vertices,**
- ▼ **By angle in the CS plane,**
- ▼ **By the CS axis,**
- ▼ **By coefficients,**
- ▼ **By two angles,**
- ▼ **By a straight-line edge, axis or perpendicular to curve plane,**
- ▼ **By a cylinder axis or perpendicular to a flat face, surface,**
- ▼ **Perpendicular to a face at the specified point,**
- ▼ **By basis vector at point of curve,**
- ▼ **Perpendicular to the screen plane.**

Select a vector drawing option from the **Method** list or using commands of the context menu. The elements for managing construction will appear on the Properties Bar (Fig. 2.8.13).

Fig. 2.8.13. Property Bar when you create a vector **By two vertices**.

Set parameters and specify objects used for construction. Parameter input and object specification for each method is detailed in Sections 2.8.5.1— 2.8.5.10.

The vector ghost appears in the model when all the required data have been specified. Phantom length does not depend on the model display scale.

To change objects used for vector construction, press the **Reselect** button on the Special Control Panel and re-select objects.

To finalize the construction, click the **Create Object** button on the Special Control Panel.

The system will resume the object construction process.

2.8.5.1. Drawing by two vertices

By two vertices is a method to draw a vector by two point objects.

By default, the system waits for the vector origin to be specified, with the **Vertex1** switch active. Specify the vector origin in the Model window or in the Design Tree. After the vector origin is specified, the system waits for specification of the point to which the vector will be directed, with the **Vertex2** switch active. Specify the point defining the vector direction in the Model window or Design Tree.

Names of selected point objects will be displayed in the **Vertex1** and **Vertex2** fields.

The ghost vector directed from the first specified point to the second one will be displayed in the screen. This is **Forward Direction**. Activate the **Reverse Direction** switch in the **Direction** group to change the vector direction.

2.8.5.2. Drawing by the angle in the CS plane

Angle in the CS plane is a method to draw a vector by specifying a coordinate system, one of its axes and a vector inclination angle relative to this axis. The vector plane will be defined according to the selected axis:

- ▼ if axis X is specified, the vector angle is measured in XY plane,
- ▼ if axis Y is specified, the vector angle is measured in YZ plane,
- ▼ if axis Z is specified, the vector angle is measured in ZX plane.

The vector origin coincides with the origin of the selected coordinate system.

After you select this drawing method, the ghost vector with the default settings will be displayed in the screen.

Select a coordinate system in the **CS** list to draw a vector.

If the model does not contain LCS, the **CS** list is not available. In this case, the vector will be constructed in the absolute coordinate system.

Select the coordinate system axis to measure the vector angle. To do this, activate the desired switch in the **CS Axis** group:

- ▼ **X Axis**,

- ▼ **Y Axis**,

- ▼ **Z Axis**.

Enter vector inclination angle value in the **Angle** field or select it from the drop-down list.

All updates will be displayed on the ghost vector in the model window.

2.8.5.3. Drawing along CS axis

Along CS axis is a method to draw a vector by selecting a coordinate system and specifying its axis along which the vector will be directed.

After you select this drawing method, the ghost vector with the default settings will be displayed in the screen.

Select a coordinate system in the **CS** list to draw a vector.

If the model does not contain LCS, the **CS** list is not available. In this case, the vector will be constructed in the absolute coordinate system.

The vector origin coincides with the origin of the selected coordinate system.

Select the CS axis to specify the vector direction. To do this, activate the desired switch in the **CS Axis** group:

▼ **X Axis**,

▼ **Y Axis**,

▼ **Z Axis**.

By default, the vector direction coincides with the direction of the selected axis. This is the **Forward Direction**. To reverse the vector direction, activate the **Reverse Direction** switch in the **Direction** group.

All updates will be displayed on the ghost vector in the model window.

2.8.5.4. Drawing by coefficients

By coefficients is a method to draw a vector by selecting a coordinate system and specifying vector expansion coefficients along its coordinate axes X, Y, Z. The expansion coefficients define the vector direction in space.

After you select this drawing method, the ghost vector with the default settings will be displayed in the screen.

Select a coordinate system in the **CS** list to draw a vector.

If the model does not contain LCS, the **CS** list is not available. In this case, the vector will be constructed in the absolute coordinate system.

The vector origin coincides with the origin of the selected coordinate system.

Enter vector expansion coefficients along the coordinate axes of the selected coordinate system in the **X**, **Y**, **Z** fields on the Property Bar.

The resulting direction is the **Forward Direction**. To reverse the vector direction, activate the **Reverse Direction** switch in the **Direction** group.

2.8.5.5. Drawing by two angles

By two angles is a method to draw a vector by selection of a coordinate system and indicating the azimuth and zenith angles that specify vector direction.

After you select this drawing method, the ghost vector with the default settings will be displayed in the screen.

Select a coordinate system in the **CS** list to draw a vector.

If the model does not contain LCS, the **CS** list is not available. In this case, the vector will be constructed in the absolute coordinate system.

The vector origin coincides with the origin of the selected coordinate system.

Vector direction is determined by two angles, A and B. The A angle corresponds to the azimuth angle α of the spherical coordinate system, and the B angle - to the zenith angle β .

The origin of the spherical coordinate system coincides with that of the vector coordinate system.

Azimuth angle α is measured in the XY plane of the vector coordinate system from the X axis counterclockwise (Fig.2.8.14). The OA ray is drawn in the XY plane at the azimuth angle to the X axis.

The OD half-line is drawn in the plane passing through the Z axis and the OC half-line at the zenith angle to the Z axis. This half-line defines the direction of the vector being drawn.

Fig. 2.8.14. Determining vector direction by azimuth and zenith angles

Enter or use the counter to specify azimuth and zenith angle values in the **A** and **B** fields on the Property Bar.

All updates will be displayed on the ghost vector in the model window.

2.8.5.6. Drawing along straight-line edge, axis or perpendicular to curve plane

Along straight-line edge, axis or perpendicular to curve plane is a method to draw a vector by specifying a guide object.

This method can use any rectilinear object as a guide object (see Table 2.1.7 on p. 131) or a flat curve: sketch line, arc, circle, edge in the form of arc/circle/ellipse.

Specify the guide object in the model window or in the Design Tree.

The ghost vector will be displayed.

- ▼ If a straight-line edge or axis is selected as the guide object, the vector will be directed along the selected object.
- ▼ If a plane curve is selected as the guide object, the vector will be directed perpendicular to the curve plane.

You can change direction of the axis being created using the **Direction** group of switches.

2.8.5.7. Drawing along a cylinder axis or perpendicular to a flat face, surface

Along a cylinder axis or perpendicular to a flat face, surface is a method to draw a vector by specifying a guide object.

This method can use any flat object as a guide object (see Table 2.1.7 on p. 131) or any rotation surface, except for the spheric one.

Specify the guide object in the model window or in the Design Tree.

The ghost vector will be displayed.

- ▼ If a flat object is selected as the guide object, the vector will be directed perpendicular to the selected object.
- ▼ If a revolution surface is selected as the guide object, the vector will be directed along the revolution axis.

You can change direction of the vector being created using the group of switches **Direction**.

2.8.5.8. Drawing perpendicular to a face at the specified point

Perpendicular to a face at the specified point is a method to draw a vector perpendicular to the specified face at the set point. Point position is set by the offset of a theoretical surface of the specified face along the U and V isoparametric curves (on the theoretical surface, see Section 2.5.1.3 on p. 328).

By cursor, select the required face in the model.

The following will appear on the selected face: ghost of its theoretic surface and vector ghost. The ghost of the theoretical face surface is displayed as a grid of the U and V isoparametric curves. The vector starts at the face indication point and is perpendicular to it at this point.

The **Face** field of the Property Bar displays the name of the selected face. The input fields **U Parameter, %** and **V Parameter, %** display values of the U and V parameters at the face indication point.

Define the vector origin. For this purpose, enter the required values of the U and V parameters in percent (from 0 to 100) in the **U Parameter, %** and **V Parameter, %** fields or use the counter to specify them. Change in the offset of the vector origin point is displayed on its ghost in the Model window.

By default, the vector direction coincides with the face normal direction at the specified point. This is the **Forward Direction**. To reverse the vector direction, activate the **Reverse Direction** switch in the **Direction** group.

2.8.5.9. Drawing along the basis vector at a curve point

Along the basis vector at a curve point is a method to draw a vector by specifying position of its origin point on a curve and selecting the basis vector of the curve at this point. The selected reference vector defines direction in space of the vector being created.

For more information on basic vectors, see Section 2.5.1.5 on p. 331.

You can select a 3D curve, sketch line, edge or a polyline segment as a curve.

Position of the vector origin is set by displacement along the curve for certain distance from its vertex.

To construct a vector, complete the following steps.

1. Specify the curve to draw a vector in the model window. You can select a 3D curve in the Design Tree.

The **Curve** field of the Property Bar will display the name of the selected object.

Two ghosts will be created on the curve: the tangent vector and the starting vertex of the curve with a directional arrow to count offset. The tangent vector starts at the indication point.

2. Set the vector origin offset along the curve.

The point offset is preset in the range of 0 - 100% of the curve length. The offset in the start vertex is 0.

After the curve is selected, the **% of the curve length** field will display the offset at the indication point. Enter or use the counter to specify the required point offset value.

3. Select vector direction. To do this, activate the desired switch in the **Vector** group:

- ▼ **Tangent Vector**,

- ▼ **Vector of the principal normal**,

- ▼ **Binormal vector**.

The obtained direction is the **Forward Direction**. To reverse the vector direction, activate the **Reverse Direction** switch in the **Direction** group.

2.8.5.10. Drawing perpendicular to the screen plane

Perpendicular to the screen plane is a method to draw a vector perpendicular to the screen plane.

Once this method is selected, the vector ghost will appear in the middle of the screen. This is the **Forward Direction**. To reverse the vector direction, activate the **Reverse Direction** switch in the **Direction** group.

Use the **Fix Position** option to fix the current position of the vector in space.

- ▼ If enabled, this option allows vector to rotate together with the model when you change model orientation.
- ▼ If the option is disabled, vector remains in the middle of the screen being directed perpendicular to it irrespective of any change in the model position.

2.8.6. Composition geometry

Composition geometry is a part of a model which represents a set of objects defining the basic geometrical parameters of the model. For example, it can define the following:

- ▼ assembly spatial domains restricting its components;
- ▼ fastening points;
- ▼ end positions of moving assembly elements (if any),
- ▼ restrictions of dimensions,
- ▼ location of individual parts of an item, etc.

Composition geometry components are, among others, parts, assemblies and local parts.

Parts and assemblies inserted into the model as composition geometry are stored in separate files. In fact, a model contains only links to the files of these parts and assemblies. When migrating such a model to another workplace, the files of all parts and assemblies which compose its composition geometry should also be migrated.

A local part built in the model as a composition geometry is stored directly in the file of this model.

Composition geometry is added into a model from a file of another model (see Section 2.8.6.1.1 on p. 620) or is created in the context of the current model (see Section 2.8.6.1.2 on p. 621).

Then you are able to edit the composition geometry in the context of the current model. When a composition geometry is stored in another file (part or assembly), you can also open it for editing in a separate window. Editing methods are described in Section 2.8.6.2.1 on p. 623.

You can insert a model as a composition geometry into multiple models, and vice versa, a model can contain multiple instances of the same composition geometry.

Composition geometry items (faces, edges, bodies, etc.) can be used when you design various objects in the model. Note that the composition geometry itself does not change.

Since a composition geometry is not a part of an item, the composition geometry is not taken into account when creating reports and specifications for the model.

Composition geometry is not used in determining the MP model.

By default, the composition geometry is placed on a special layer called *Composition geometry*; when there exist multiple layers with this name (you can add or remove these layers), the composition geometry is placed on the smallest one of them. When the layer *Composition geometry* is missing in the model, the system will create it automatically. By default, the automatically created layer is not projected into the associative drawing. You can also enable projecting if required or move a composition geometry to another layer. Working with the dialogs is described in Section 2.15.13 on p. 845.

In general, designing composition geometry is similar to designing components. However, unlike the components, the composition geometry does not support the following operations:

- ▼ enabling/disabling fixing,
- ▼ merging into a subassembly and exploding a subassembly,
- ▼ conversion into a local part using the **Embed in document** command.

The only objects you can merge into a macro item are those included into the components of the composition geometry. You cannot merge these components into a macro item.

2.8.6.1. Adding a composition geometry into a model

You can create a composition geometry either in the current model (“in place”, see Section 2.8.6.1.2 on p. 621) or copy it from another model stored in a file (see Section 2.8.6.1.1).

When working with an assembly, you can use the create/add commands for the composition geometry from the **Operations menu** or by clicking the corresponding buttons on the **Edit assembly** panel. A button to add a composition geometry from a file is also available on the **Edit model** panel.

When working with a part, you can add a composition geometry by clicking the button on the **Edit part** panel. To create a new composition geometry “in place”, enable the **Edit assembly** panel by choosing **View — Toolbars — Edit assembly** or by adding the create command for the composition geometry on any toolbar.

In addition to the methods above, you can also create a composition geometry by converting a component into it (see Section 2.8.6.1.3 on p. 622), as well as by converting model objects into a part (see Section 2.11.2.3.1 on p. 689) or local part (see Section 2.11.2.3.2 on p. 691).

2.8.6.1.1. Adding a composition geometry from a file

To add a part or an assembly from a file into a model as a composition geometry, perform the following.

1. Call the **Operations — Add from file — Component...** command or click the **Add from file** button on the **Model/Detail Editing** or **Assembly Editing** bar.
2. Select the file, containing the required model, in the dialog appeared on screen.

If this part contains variants, geometry and properties of the base part will correspond to one of these variants. The list of all variants, that exist in the model, is contained in the **Variant** list of the file selection dialog. Specify the required variant in the list.

If additional numbers of variants are created in the chosen model, the dialog will also contain the **Additional Number** list. By default, the list has the activated variant under which none of the additional numbers is selected (empty line of the list). If necessary, choose the line with the required number.

3. To finish the file selection, click the **Open** button.

The dialog will close and the current model will be updated with the new composition geometry containing a model from the selected file. The absolute coordinate system of the new subassembly will match the absolute coordinate system of the current assembly.

The absolute coordinate system of the model from the file will match the absolute coordinate system of the current model. To do this, enable the editing mode for this geometry and activate the necessary coordinate grids for the models (for details, see Section 2.8.6.2.2 on p. 623).

In the Design Tree of a model the icon will display in the *Composition geometry* section depending on the type of the composition geometry (part or assembly). The component name, retrieved from it's file, shall appear next to the icon.

The model should be rebuilt after adding a composition geometry (for details on rebuilding, see Section 2.14.3.7 on p. 795).

If the component inserted in the assembly is a model's variant, you can replace it by another variant of the model. For this purpose, call the **Current variant** command from the component's context menu in the Design Tree and specify the required variant in the appearing list of the model's variants. A tick will appear next to the designation of the chosen variant in the list. This will result in inserting the version in the model. Once the version is selected, rebuild the model (for details on rebuilding, see Section 2.14.3.7 on p. 795).

2.8.6.1.2. Creating composition geometry "in place"

To create a new library, do the following.

1. Choose **Operations – Create – Composition geometry...** command or click the **Create composition geometry** button on the **Edit assembly** bar. The **Set up columns** dialog will be displayed (Fig. 2.8.15).

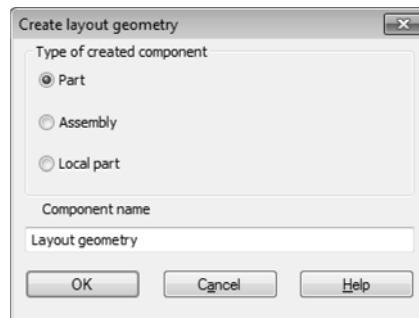

Fig. 2.8.15. The **Create composition geometry** dialog

2. Specify the type of the composition geometry to be created. To do this, select one of the following options in the **Type of component being created** group:
 - ▼ **Part** — to create a part stored in a separate file,
 - ▼ **Assembly** — to create an assembly stored in a separate file,
 - ▼ **Local Part** — to create a local part stored in the current model.
3. Type the name of the composition geometry in the **Component name** field and then click **OK**.

If you are creating a part or an assembly, the file save dialog will appear. Specify the folder and name of the file for the new part or assembly and click **Save**. The Design Tree of the model will display the icon in the *Composition geometry* section denoting the new part or assembly, and the system will switch to the contextual editing of this part or assembly.

If you are creating a local part, you don't need to enter the file name since local parts are stored in the same model. The system immediately switches to the contextual editing of the local part, and in the *Composition geometry* section of the Design Tree the corresponding icon appears.

The absolute coordinate grid of the part, assembly or local part being created is the same as the currently used coordinate grid of the model.

4. Perform all necessary actions to create a part, assembly or local part in the contextual editing mode. Operation in this mode is described in Section 2.11.6.2.1 on p. 724. To exit from this mode, deactivate the **Edit in place** button on the **Current status** panel or choose the **Edit In**

place from the shortcut menu of a part or assembly or click the contextual mode icon in the model window. The system will switch to the current part mode.

Once the contextual editing of a part, assembly or local part is complete, the model should be rebuilt (for details on rebuilding, see Section 2.14.3.7 on p. 795).

For details on how to work with local parts, see Section 2.11.6.5 on p. 726.

If the current model and/or its nested composition geometry (a part, assembly or local part) contains local coordinate grids, then you will be able to relocate the layout model later. To do this, enable the editing mode for this geometry and activate the necessary coordinate grids (for details, see Section 2.8.6.2.2 on p. 623).

2.8.6.1.3. Converting a component into a composition geometry

To convert a model component into a composition geometry, specify the required component in the Design Tree and choose **Editor — Move to composition geometry**. If the Design Tree already contains a section called *Composition geometry*, you can simply drag the component to the icon of this section.

The icon of the selected component in the Design Tree will be moved to the *Composition geometry* section. The component will be assigned the properties of the composition geometry and will become available on the *Composition geometry* layer.

Positions of the component objects in the model window will not change. However, if the absolute coordinate grid of the component matches none of the model's coordinate grids, then the system will create a matching coordinate grid in the model.

If you want to convert multiple components of the model into a composition geometry, select them in the Tree and then choose **Editor — Move to composition geometry**.

You can also perform back conversion of the composition geometry into a component. You can do so when the *Components* section is available in the Design Tree. To perform conversion, drag the composition geometry you want to the icon of this section.

The model should be rebuilt after converting a component into a composition geometry or vice versa (for details on rebuilding, see Section 2.14.3.7 on p. 795).

2.8.6.2. Editing a composition geometry

When editing a composition geometry, you can do the following:

- ▼ edit objects of the composition geometry (see Section 2.8.6.2.1),
- ▼ change parameters of the composition geometry (see Section 2.8.6.2.2 on p. 623),
 - ▼ change the position of the composition geometry in the model,
 - ▼ change the properties of the composition geometry,
 - ▼ choose another source file for the composition geometry,
 - ▼ recalculate the dimensions of the composition geometry with the assigned tolerances.

2.8.6.2.1. Editing composition geometry items

To edit objects of a composition geometry open it in a separate window or switch to the contextual editing mode for the composition geometry. This done, you can now use any editing techniques described in Section 2.14.3 on p. 786.

Note that editing in a separate window is available only when the composition geometry in the model was created from a part or an assembly. You can edit a composition geometry created from a local part only in the context of the current model.

To edit a composition geometry in a separate window, select it in the Design Tree and choose **Edit in window from the shortcut menu**. The source file of the composition geometry will open. You can also open this file as usual by choosing **File — Open**.

Once you make all necessary changes, save and close the source file for the composition geometry or return to the window of the model containing your composition geometry.

You can also save a copy of the composition geometry you edit into another file or location on hard disk drive. Saving methods are described in Section 2.11.6.1.1 on p. 723.

To edit a composition geometry in the context of the current model, select it in the Design Tree and choose **Edit in place** from the shortcut menu. The system will switch into a composition geometry editing mode. Operation in this mode is described in Section 2.11.6.2.1 on p. 724.

To complete editing the component 'in place', use **Edit in place** command once again or release the **Edit in place** button, or click the context editing mode icon in the model window. The system will return to main model operation mode.

Note the following specifics when inserting curve functions.

When a composition geometry is a part or an assembly, the changes are made directly in the file of this part of assembly. That is why the prompt to save the component file appears when editing is complete.

When a composition geometry is a local part, the save file dialog does not display since local parts are stored directly in the model rather than in separate file.

The model should be rebuilt after changing objects of a composition geometry (for details on rebuilding, see Section 2.14.3.7 on p. 795).

2.8.6.2.2. Changing a position and parameters of composition geometry

To change a position of a composition geometry in the model, select it in the Design Tree and choose **Place a component** from the shortcut menu or choose the **Edit** command from the **Editor** menu. Additional controls will become available on the Property bar.

Controls for changing the position are available on the **Location** tab (Fig. 2.8.16).

Fig. 2.8.16. The **Location** tab

On this tab, you can change the position of the composition geometry in the model. The tab provides drop-down lists of coordinate grids of the composition geometry and the current model. These drop-down lists are available when the composition geometry and the current model contain local coordinate grids.

To change a position of a composition geometry, choose the coordinate grids for alignment.

There is a button next to each drop-down list allowing you to specify the necessary coordinate grid from the Design Tree or model window rather than from drop-down lists. You can choose the coordinate grid for the composition geometry by clicking **Component CS**, and choose the coordinate grid for a model by clicking **Current document CS**.

The selected coordinate grids will be overlaid and the position of the composition geometry in the model will change.

You can also configure other parameters of the composition geometry as required.

On the **Properties** tab you can set the color and optical properties of the composition geometry appearance. Control elements used for this are described in Section 2.14.2 on p. 784.

On this tab you can also include or exclude the composition geometry from the calculation. Switches in the **Status** group are used for this.

You can also choose new values of variables in the source model for the composition geometry if the model contains a table of variables. For this, you need to click the **Table of Variables** button and select the required row in the table that appears on the screen.

To configure parameters of the composition geometry without changing its position, you can use the **Component properties** option from the context menu.

To confirm the dimple, click the **Create Object** button on the Advanced Control Panel.

2.8.7. Copies of geometrical objects

A copy of geometrical objects is a model object containing geometrical objects which do not have any history and represent copies of geometrical objects of this model or another one.

The sources of geometrical objects within the same copy must be placed in the same document.

The object in the copy is associated with its source object. All changes in the source object are mirrored in its copy. When the source object is placed in the same document, all changes are mirrored automatically. When the source object and its copy are placed in different documents, you need to rebuild the mode containing a copy in order to mirror the changes (for details on rebuilding, see Section 2.14.3.7 on p. 795).

Each copy of geometrical objects can contain the following model objects:

- ▼ bodies,
- ▼ surfaces,
- ▼ faces,
- ▼ edges,
- ▼ verticals,
- ▼ 3D curves and points,
- ▼ Auxiliary axes and planes,
- ▼ coordinate systems,
- ▼ sketches.

The copy can include objects of the model itself, its components and composition geometry that it contains.

You can change the objects in the copy later as well as use them for building various objects in the model.

2.8.7.1. Creating a Copy of Geometrical Objects

To create a copy of geometrical objects, use the **Copy objects** command from **Operations – Additional controls** or click **Copy objects** on the **Edit model** panel.

If you want to add the objects from the current model into a copy, then you can select the necessary objects either before or after running this command.

If you want to add the objects from another model into a copy, then you can select the necessary objects only after running this command.

The list of possible objects is shown in Table 2.8.7 on p. 624.

When this command has been initiated, **Parameters** and **Properties** tabs appear on the Property bar.

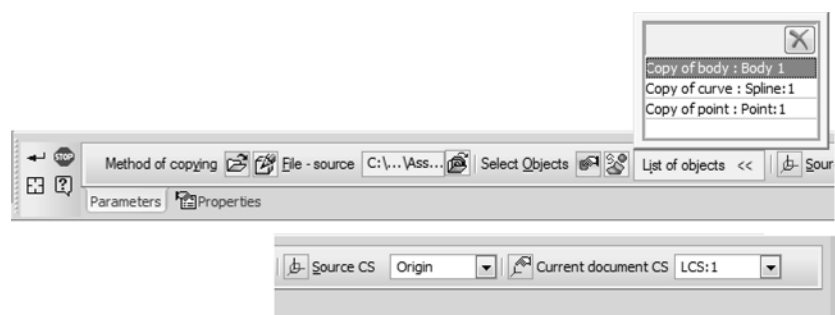

Fig. 2.8.17. **Parameters** Tab

On the **Parameters** tab (Fig. 2.8.17) perform the following actions.

1. Use the **Method** switch group to choose the rectangle's construction method.

By default, the **Context** switch is enabled in the group. In this case, choose the objects for copying in the current model.

To create a copy of objects from another model, activate the **From file** switch. The file selection dialog will appear. Specify the source file for choosing objects and then click **Open**.

The Properties panel will display a field showing the full name of the selected file and the **Source file** button for choosing another file when required. The model window will display the Source model window (see Section 2.8.7.1.1).

- Using switches in the **Object selection** group, specify the method of creating a set of objects included in the copy. There are two options: arbitrary choosing the objects and choosing a set of objects (see Section 2.8.7.4 on p. 629).

By default, the **Manual selection** switch is enabled which corresponds to arbitrary choosing of objects. The names of the selected objects will appear in the **List of Objects** toolbar.

To add an object into a list, specify it in the Design Tree or in the window of the model that you've previously selected as a copy source (current model for the context copying or the model displayed in the window of the source model for copying from file). The selected object is highlighted. Its ghost will appear in the window of the current model.

To remove an object from the list, click it again. You can also delete an object by selecting it on the list and clicking the **Delete from list** button. The **Select other** button empties the list.

You can specify a body or a surface only in the Design Tree.

If another building operation for a body or a surface is specified in the Design Tree, e.g. extrusion, then all faces of this body (surface) will be copied.

To choose a set of objects, activate the **Collections** switch. The Properties bar will display the drop-down list of collections available in the current model (for context copying) or in the model from a file (for copying from file). Select the required measurement unit from the list.

The list of collections is shown on the Properties bar when the document selected for copying contains at least one collection.

Once you've selected objects using one of the above methods, the window of the current model will display the ghosts of the selected objects.

- Specify the position of the copy in the model. For this, do the following.

▼ When the objects are copied from the current model, the copy is placed in the current coordinate grid of the model by default. To change the position of the copy, make another coordinate grid the default one. To do this, select it from the **Current document CS** list or click the corresponding button and specify the coordinate grid you want in the Design Tree or a model window.

▼ When the objects are copied from another model, the absolute coordinate grid of the source model by default matches the current coordinate grid of the model where the copy is being created. To change the position of the copy, specify another coordinate grid for overlaying. To do this, choose them from the **Source CS** and **Current document CS** lists. You can also use the buttons on the Properties bar to choose the coordinate grids. Once you click the button, you will be able to specify the option in the Design Tree

or window of the current model (for the coordinate grid of the current document) and in the Design Tree or in the window of the source model (for the coordinate grid of the source model).

The controls for choosing the coordinate grids are available when the current model and/or source model contain local coordinate grids.

4. On the **Properties** tab, specify the name of the new copy of objects.

5. To finish the construction of the curve click the **Create Object** button on the Special Control Panel.

In the *Copies* section of the Design Tree of the model, the icon and name of the created copy of object will appear, and in the window of the current model, the objects included in this copy will display.

2.8.7.1.1. Variables Window

The window of the source model is displayed in the window of the current model when another model file is used for a source of the objects included in the copy.

This window contains an image of the source model and the Design Tree of the current model (Fig. 2.8.18).

Fig. 2.8.18. Window of the Source Model

The source model's Design Tree displays the following objects:

- ▼ coordinate systems,
- ▼ construction geometry,
- ▼ layout elements (unavailable for copying),
- ▼ curves and points,
- ▼ sketches,

- ▼ bodies constructed directly in the source model,
- ▼ 'dimension' objects (unavailable for copying).

You can specify objects in the window of the source model as usual by clicking them in the Tree or directly in the window.

You can move the source model window by dragging it by the header. You can also resize the window by clicking and dragging its borders. Moving or resizing the window are only possible within the window of the current model.

Type of displaying objects in the window (wireframe, shaded, etc.) corresponds to the selected in the current model window.

You can also zoom in or zoom out the objects in the window using the **Show All** and **Current Zoom** commands, as well as by scrolling the mouse wheel.

You can also control the display of the objects in the window using the commands **View — Hide**.

You can also rotate the model in the window using your keyboard (see *Rotating a model using the keyboard* on p. 120) or mouse (see *Rotating the model using the mouse* on p. 120).

2.8.7.2. Editing a Copy of Geometrical Objects

To edit a copy of geometrical objects, select it in the Design Tree and choose **Edit** from the **Editor** menu or from the shortcut menu. The same controls as those available for inserting a component to the assembly will be active on the Property bar.

The same controls as those available for creating a copy will be active on the Properties bar. This can be done using the same method as for copy creation (see Section 2.8.7.1 on p. 625).

2.8.7.3. Explosion of a Copy of Geometrical Objects

A copy of geometrical objects contain objects associated with the source objects, but without history. You can explode an existing copy into separate objects. After explosion, the links between the objects in the copy and the source objects will be disposed. The model will contain a set of objects without history.

To explode a copy, select it in the Design Tree and then choose **Explode** from the **Editor** menu or from the shortcut menu.

To explode multiple copies, select them in the Design Tree and then choose the command from the **Editor** menu.

Upon calling the command, an explode dialog will appear. To confirm the breaking, press the **OK** button. The **Cancel** button closes the dialog and rejects all changes.

After explosion, the icon of the exploded copy will be removed from the model. The copies of the objects are displayed in the Design Tree separately and preserve their position within the model.

2.8.7.4. Collections

A collection is an arbitrary set of objects. Usually, collections are used for storing objects required for certain building operations. For example, a collection can contain faces of the adjacent surfaces and/or other faces of the surrounding parts which define the position and configuration of the newly created component.

Collections are used for picking objects when creating copies of geometrical objects (see Section 2.8.7 on p. 624). They allow you to quickly pick the necessary objects without clicking them in the Design Tree or model window.

A collection can contain the following model objects:

- ▼ bodies,
- ▼ surfaces,
- ▼ faces,
- ▼ edges,
- ▼ verticals,
- ▼ 3D curves and points,
- ▼ Auxiliary axes and planes,
- ▼ coordinate systems,
- ▼ sketches.

A collection can also include the objects from the current model, its components or its nested composition geometry.

To create a collection, choose **Operations — Additional Controls — Collection** or click the **Collection** button on the **Edit Model** panel.

Parameters and **Properties** tabs will appear on the Property bar.

The **Parameters** tab provides the **List of Objects** panel allowing you to create a set of objects to be included into the collection. You can select the surfaces either before or after calling the command.

To add an object to the list select it in the Design Tree or in the Model window.

You can specify a body or a surface only in the Design Tree.

To remove an object from the list, click it again. You can also delete an object by selecting it on the list and clicking the **Delete from list** button. The **Select other** button empties the list.

On the **Properties** tab, specify the name of the new collection.

To finish the construction of the curve click the **Create Object** button on the Special Control Panel.

The Design Tree will display the icon of the new collection and its name. When you select a collection in the Design Tree, all its objects are highlighted in the model window.

When creating a collection in the model, no copies of the selected objects are created. A new collection will contain the original objects.

You can change the set of objects in the collection and its name later. To do this, select a collection in the Design Tree and choose **Edit** from the **Editor** menu or from the shortcut menu. The same controls as those available for inserting a component to the assembly will be active on the Property bar. The collection can be modified in the same way as it is created.

2.9. Dimensions, designations, thread (notation)

2.9.1. General Information

KOMPAS-3D allows creating different sets of dimensions and designations in 3D models.

Commands for creating dimensions and symbols are grouped in **Operations— Dimensions and Process Symbols** menu, and the respective buttons for these commands can be found on the **Dimensions and Process Symbols** toolbar (Fig. 2.9.1).

Fig. 2.9.1. **Dimensions and Process Symbols** toolbar

Created dimensions and designations can be transferred to a drawing when creating a model's associative views in it (see Section 3.6.1.2 on p. 1208).

Dimensions and designations transferred to the drawing are **projection designations**. Work with projection designations is described in Section 3.6.3.5 on p. 1226.

2.9.2. Dimensions

2.9.2.1. General information on dimensions

Dimensions in a model can be of two types: controlling and informational. The dimension's type defines whether the dimension will affect the model's object or, vice versa, the object will affect the dimension.

The **controlling dimension** is a dimension that controls the geometry of the model's object. The value of the controlling dimension can be changed by the user. After that, the object with the dimension is rebuilt to satisfy this new dimension value. The rectangular frame around the value indicates the controlling dimension. This frame is not printed out.

The **informational dimension** is a dimension controlled by the model's object. It is impossible to change the value of the informational dimension. If the object, to which the informational dimension is assigned, has been rebuilt, the dimension will be rebuilt with recalculation of its value.

When working with a model, you can use **dimensions of sketches and operations**. Besides that, you can create **dimensions that are layout elements**.

- ▼ **Dimensions of sketches and operations:** they are not displayed in the Design Tree; they are visible only during creation of an operation or in the special mode; they can be both controlling and informational; they are not transferred to the drawing; more information about dimensions of sketches and operations can be found in Section 2.9.2.2 on p. 632.
- ▼ **Dimensions — layout elements:**

- ▼ **derivative dimensions** are dimensions of sketches and operations represented as layout elements; they inherit the type of respective dimensions; in the Design Tree, they are displayed as subordinate objects of sketches and operations; they can be transferred to the drawing; more information about derivative dimensions can be found in Section 2.9.2.8 on p. 648;
- ▼ **dimensions manually assigned to a model**; they are always informational; in the Design Tree, they are displayed as individual objects of the model; they can be transferred to the drawing; more information about manually assigned dimensions can be found in Section 2.9.2.3 on p. 637.

Appearance of derivative dimensions and manually assigned dimensions are the same (for example, arrow length and angle, font and position of the dimension text and so on), since it is controlled by the model dimensions settings (see Section 9.2.7.2 on p. 1836). Display color is the only difference between derivative dimensions and manually assigned dimensions (by default, the derivative dimensions color is violet, while the color of manually assigned dimensions is brown). See Section 9.2.7.4.7 on p. 1850 for more information about adjusting the color of model objects' display.

2.9.2.2. Dimensions of sketches and operations

In KOMPAS-3D, most operations have a certain set of numeric parameters. If an operation parameter's value is expressed in linear or angular values, the parameter can be displayed as the dimension of the respective type – an **operation's dimension**. For example, numeric parameters of the extrusion operation are as follows: extrusion distance, slope angle, and wall thickness.

Dimensions of operation are displayed on the screen in the following cases:

- ▼ when performing an operation;
- ▼ in the special **mode of displaying the selected element's dimensions** (see Section 2.9.2.2.2 on p. 635).

For each numeric parameter of the operation, a variable is created automatically. The variable's name is displayed in parenthesis below the dimension line of the dimension that corresponds to the operation's parameter (Fig. 2.9.2).

Fig. 2.9.2. Example of extrusion element construction

Dimensions of a sketch with variables can also be viewed in the dimensions display mode. Besides that, sketch dimensions are displayed when performing the operation if the sketch is involved in its creation.

When performing an operation, dimensions of sketches and operations are displayed on the screen, if the dialog for customization of display parameters of dimensions and designations (see Section 9.1.11.12 on p. 1736) has the **Dimensions of sketches and operations** option enabled.

When working with an array, you can enable the display of the dimensions of sketches and operations for each copy of the array (see Section 2.7.2.4 on p. 536).

Dimensions of sketches and operations can be both controlling and informational (see Section 2.9.2.1 on p. 631).

Dimensions of sketches and operations are not displayed in the Design Tree.

You can enable or disable displaying the names of variables and the “controlling” sign in the dimensions of sketches and operations (see Section 2.9.2.2.3 on p. 637).

If necessary, you can change the value of the dimension of the sketch or operation. Changing the dimension’s value is possible both when performing the operation (see Section 2.1.4.2.3 on p. 139) and after it in the mode of displaying the dimension chosen for elements (see Section 2.9.2.2.1 on p. 634).

If necessary, you can display dimensions of sketches and operations as layout elements (see Section 2.9.2.8 on p. 648). As a result, **derivative dimensions** corresponding to dimensions of sketches and operations will appear in the Model Window. In the Design Tree, derivative dimensions are displayed as subordinate to sketches and operations (see Fig. 2.9.18 on p. 648).

2.9.2.2.1. Setting the dimension's value

You can edit the values of the following dimensions:

- ▼ associative dimensions of a sketch and dimensions of an operation when performing the operation or in the mode of displaying the selected element's dimensions (for more information about the mode, see Section 2.9.2.2.2 on p. 635);
- ▼ manually assigned dimensions (see Section 2.9.2.3 on p. 637),
- ▼ dimensions of a sketch or operation presented as layout elements (derivative dimensions; see Section 2.9.2.8 on p. 648).

When performing an operation, dimensions of a sketch and operation are displayed on the screen, if the dialog for customization of display parameters of dimensions and designations (see Section 9.1.11.12 on p. 1736) has the **Dimensions of sketches and operations** option enabled.

Enter a dimension value in the dimension value setting dialog (Fig. 2.9.3).

Fig. 2.9.3. Dialog to set dimension value: a) operation, b) sketch

The dialog appears on the screen after:

- ▼ double-clicking the dimension's dimension text;
- ▼ calling the **Set dimension value** command from the context menu of the derivative dimension selected on the Design Tree or in the model window.

In this dialog you can perform the following actions.

- ▼ Edit the name of a variable (only for sketch dimension and manually-assigned dimension).
- ▼ Input desired dimension value¹: number, constant, or expression for calculation of the dimension value (the expression syntax is described in Section 7.1.3.3.1 on p. 1580).

- ▼ Assign individual tolerance using the **Assign tolerance** button:
 - ▼ for the value of an operation's parameter,
 - ▼ for a sketch dimension,
 - ▼ for a manually-set dimension.

Assignment of tolerances is described in Section 2.10.2.2 on p. 669.

- ▼ Input a comment for a variable.

- ▼ convert the controlling dimension into informational or vice versa, using the button **Info Dimension** (only for sketch dimension),

- ▼ enable automatic rebuilding of a model after setting the dimension's value (closing the dialog) using the **Rebuild** button.

1. For the sketch's dimension, you can enter the value only if the dimension is the controlling one. Otherwise, the field for the dimension's value entry will not be available.

Upon completing dimension editing, press the **Create dimension** in the dialog.

- ▼ If automatic model rebuilding is enabled in the dialog, the image on the screen will be rebuilt in accordance with the new value of the dimension.
- ▼ If automatic model rebuilding is disabled, the image on the screen will no be changed. In order to rebuild the model, click the **Rebuild** button on the **View** bar or press <F5>. The image on the screen will be rebuilt in accordance with the new value of the dimension.

Note the following peculiarity when editing the value of the dimension of a sketch or operation *in the process of performing the operation*. Once the dimension value in the **Set the dimension's value** dialog is changed, the ghost of the object being created will be rebuilt irrespective of the **Rebuild** button status (see above).

2.9.2.2.2. Displaying dimensions of sketches and operations in the Model Window

When working with the model, you can view:

- ▼ controlling dimensions of the operation, that creates the object, without entering the process of its editing,
- ▼ controlling dimensions of a sketch with variables outside the mode of the sketch editing.

For this purpose, the **special mode of displaying dimensions of the selected element** is used.

Besides that, you can change the values of dimensions of sketches and operations in this mode.

In order to enable the mode of displaying dimensions of the selected element, click the **Dimensions of selected element** button on the **Modes** bar or select its name in the **View** menu. The **Dimensions of the Selected Element** button is available if none of the 3D construction commands is active.

Choose the required object by selecting it in the Design Tree or specify any of its primitives in the Model Window: a face, edge, or vertex.

Dimensions of the highlighted object will be displayed on the screen (Fig. 2.9.4).

Fig. 2.9.4. Example of displaying dimensions of a selected object:
a) sketch, b) extrusion element

If an object is selected, and its dimensions are not displayed in the Model Window, it means that:

- ▼ the operation has no numeric parameters expressed in linear or angular values;
- ▼ the sketch has no controlling dimensions, or the sketch's controlling dimensions do not have a variable.

To adjust the dimension's value, double-click its dimension text. The dialog to set the dimension value will be displayed. Specify the required dimension value in this dialog (see Section 2.9.2.2.1 on p. 634).

Peculiarities of displaying dimensions of a selected object

1. Viewing and editing are only available for the dimensions of those objects that were built directly in the model (not in any of its components). To work with a component, you need to go into the mode of in-window editing or that on the spot.
2. If an object's dimension is already presented as a derivative dimension (see Fig. 2.9.18 on p. 648), the image of the dimension (a copy of the derivative one) will not be formed in the mode of displaying dimensions.
3. Connecting lines of dimensions (for example, lines that conditionally indicate objects with dimensions, see Fig. 2.9.4, b) are displayed on the screen if the dialog for dimension and designation display setup (see Section 9.1.11.12 on p. 1736) has the **Connecting lines** option enabled.

2.9.2.2.3. Displaying names of variables in dimensions of sketches and operations

By default, the mode of displaying names of variables and the “controlling” attribute in the dimensions of sketches and operations is enabled in the model (more information about controlling dimensions can be found in Section 2.9.2.1 on p. 631).

In this mode, dimensions of sketches and operations are displayed as follows:

- ▼ values of dimensions are displayed in frames (see Fig. 2.9.4 on p. 636),
- ▼ names of variables corresponding to dimensions are displayed under their dimension lines.

If the value of an operation's numeric parameter or sketch dimensions is defined by a constant, expression, or negative number, the following information is displayed under the dimensional line of dimensions: name of the variable and its value.

In order to disabled the mode of displaying names of variables in dimensions of sketches and operations, call the **View — Names of variables in dimensions** command or press <F11>.

2.9.2.2.4. Specifics of Working with Dimensions of Operations

When editing an operation, an of its numeric parameters can become dependent on the model's object. In this case, the operation's dimension, that represents this parameter, becomes the informational one and will no longer be displayed on the screen. If this operation's dimension was presented as a layout element (derivative dimension), the derivative dimension will be deleted once editing of the operation is finished.

For example, when editing an extrusion operation, the **To Distance** construction method was replaced by the **To Vertex** method. The extrusion distance will become dependent on the position of the specified vertex. The size of operation, corresponding to the extrusion distance, becomes an informational one and will no longer be displayed on the screen. The derivative dimension, representing this operation's dimension, will be deleted.

2.9.2.3. Procedure for manual assignment of dimensions

The system allows manually assigning linear, angular, radial and diameter dimensions to objects of various types. The object to which the dimension is attached is called base object.

All dimensions manually-assigned in 3D parts and assemblies are informational dimensions (see Section 2.9.2.1 on p. 631).

To create a dimension use the appropriate dimensioning command.

If automatic dimensioning is required, click **Object Autocreation** button on the Advanced Control Panel. The automatic and manual object creation is detailed in Section 1.4.2.10 on p. 93.

If necessary, you can make more than one dimension of the same type in one dimensioning command. To do this, without leaving the command, select the objects one by one which the dimensions should be attached to. The objects can be selected in the Design Tree or in the Model window.

The created dimension will appear in the model window, while their icons will appear in the Design Tree.

To finish current command, click **Interrupt Command** button on the Advanced Control Panel.

Select Other button makes it possible to reselect objects.

Controls located in the Properties tab allow defining name of dimension in the Design Tree and color of drawing of dimensional lines.

When dimensioning with default settings, the dimension text may appear inside the body. To facilitate further manipulations with the dimension, use mouse to move the handle that determines the dimension text position so that the dimension text is displayed outside of the part.

Once attached, each dimension is automatically assigned a variable name. To change the default variable name, double-click the desired dimension's text. A **Set Value of Dimension** dialog will appear. Enter the new variable name and click **Create Dimension** button. More information about the dialog for dimension value setting can be found in Section 2.9.2.2.1 on p. 634.

The 3D model operation mode doesn't support vector fonts including the KOMPAS-3D supplied fonts GOST type A (plotter), GOST type B (plotter), Symbol type A (plotter), Symbol type B (plotter) therefore you shouldn't use them for dimension text.

Dimensions can sometimes disturb from viewing the model. To hide a dimension, select it and use **Hide** context menu item. A dimension will also become hidden if any of its objects are hidden.

Hidden dimensions will not be transferred to the drawing when associative views of the model are created in it.

To make a hidden dimension visible, select it in the Design Tree and use **Show** context menu item.

KOMPAS-3D uses such default symbol settings that are most commonly used in design documentation. If necessary, you can change these values. Dimension parameter customization for model is described in Section 9.2.7.2 on p. 1836.

2.9.2.4. Linear Dimension

For linear dimensioning, point, line and planar objects can be used.

Point objects are:

- ▼ sketch point,
- ▼ 3D point,
- ▼ 3D line vertex,
- ▼ Solid or surface vertex.

Straight objects:

- ▼ line in a sketch,
- ▼ polyline segment,
- ▼ solid or surface edge.

Flat (planar) objects

- ▼ coordinate plane,

- ▼ auxiliary (construction) plane,
- ▼ Face of the body or surface.

To create linear dimensions use the **Linear Dimension** command.

Select with the cursor an objects to set dimension.

- ▼ To attach a dimension to a straight object, select the straight object with the mouse.
- ▼ To insert a dimension between two point objects, two planar objects or a point object and a planar object, select the objects with the mouse.

Linear dimensioning between two planar objects is only possible if the objects are parallel to each other.

Select the base plane—the plane which the dimensioning plane will be parallel to.

When attaching a dimension to an edge or a line the base plane is selected by the system automatically. In the first case one of the pairs of faces divided by an edge is used as the base plane, in the second case — sketch plane.

You can change the base plane (including the automatically selected one) without exiting the command. For this enable the Plane switch on the Properties toolbar and define the required flat object.

After defining objects and base plane a ghost of the dimension will be displayed. The dimensioned segment is displayed as a dash-dot line with two points. Its ends are the dimension snapping points (points of extension line origin). The projection line of one of objects on the dimension attaching plane is displayed as a dash-dot line (the necessity of projection is defined by mutual position of objects and dimension attaching plane).

The dimensioned segment and the projection relation line will be displayed if **Show Connection Lines** option is turned on in dimension display settings (see Section 9.1.11.12 on p. 1736).

Set the position for the dimension line. For this enter the value of leader length in **Length** field of **Dimension** Tab on Properties panel (the value may be both positive and negative) or use the mouse to define points on its ends.

If necessary, edit the dimension text (see Section 3.3.1.3 on p. 979) and specify the dimension display parameters (see Section 3.3.1.2 on p. 977) using Properties bar tabs.

If the dimension text should be placed on a leader shelf, follow the procedure described in Section 2.9.2.4.1.

By default, linear dimension will be placed in the dimensioning plane to the left of the dimensioned segment. The left side of the dimensioned segment is determined as follows: A vector from the first dimension snap point to the second snap point (or its projection) is constructed. The half of the dimensioning plane to the left of this vector is considered the left side.

When adding more than one dimension in a single dimensioning command, the selected base plane will be used for all of them. To select another base plane, click **Select Other** button on the Property bar.

An example of linear dimensioning between two point objects is illustrated in Fig. 2.9.5.

Fig. 2.9.5. Linear dimensioning example

2.9.2.4.1. Placing Dimension Text on Leader Shelf

If necessary, dimension text can be displayed on a leader shelf. This can be achieved by doing the following when creating or editing a dimension.

1. Activate page MP **Parameters** of the Property Bar.
2. In the **Text Location** drop-down list, select one of the following: **On Leader Shelf Left**, **On Leader Shelf Right**, **On Leader Shelf Top** or **On Leader Shelf Bottom**.

The leader line will appear (Fig. 2.9.6).

Fig. 2.9.6. Linear dimension on leader shelf

3. Set the leader line start position and leader shelf start by moving **p3** and **p4** points with your mouse.

2.9.2.4.2. Dependency of the dimension value on the base plane selection

In all cases of linear dimension attaching, in addition to the dimension between flat and point objects, the base plane defines not only space position of dimension, but also its value.

Let's examine attaching dimensions between point objects in the model shown in Fig. 2.9.7.

Fig. 2.9.7. Point objects and possible base faces to attach dimensions

Points 1 and 2, which belong to A edge and are located in the centers of round edges are selected for dimension creation.

Fig. 2.9.8. Dependency of the position and dimension value on the base plane selection:
a) base plane— A face; b) base plane— B face c) base plane— C face

- ▼ The figure 2.9.8, a) shows the dimension which base plane is A face. Since this face contains both points 1 and 2, it also is the plane to attach a dimension. The dimension value is equal to the actual distance between points 1 and 2.
- ▼ Figure 2.9.8 b) shows the dimension the base plane of which is B face. The plane to attach the dimension is parallel to this face and passes through point 1. Point 2 is projected on the dimension attaching plane. The dimension value is equal to the distance from point 1 to the projection of point 2, i.e. the length of projection of the actual distance between points 1 and 2 to the base plane.
- ▼ Figure 2.9.8 c) shows an example, the base plane of which is C face. Its construction is similar to the previous one.

2.9.2.5. Linear Dimension from Line to Point

Linear dimension from a line to a point is created between a straight object and a point. Following objects can be used.

Straight objects:

- ▼ line in a sketch,
- ▼ polyline segment,
- ▼ coordinate axis,
- ▼ auxiliary axis,

- ▼ solid or surface edge.
On-Spot:
- ▼ sketch point,
- ▼ 3D point,
- ▼ Origin
- ▼ 3D line vertex,
- ▼ Solid or surface vertex.

To create linear dimensions from a line segment to a point use the **Linear Dimension from Line to Point** command.

Select with the cursor a straight object and then a point.

The dimension will appear in the plane running through the objects (Fig.2.9.9).

Fig. 2.9.9. Example of linear dimensioning from segment to point

Set the position for the dimension line. For this enter the value of leader length in **Length** field of **Dimension** Tab on Properties panel (the value may be both positive and negative) or use the mouse to define points on its ends.

If necessary, edit the dimension text (see Section 3.3.1.3 on p. 979) and specify the dimension display parameters (see Section 3.3.1.2 on p. 977) using Properties bar tabs.

If the dimension text should be placed on a leader shelf, follow the procedure described in Section 2.9.2.4.1.

2.9.2.6. Angular Dimension

For angular dimensioning, straight and planar objects that are sides of an angle are used.

Straight objects:

- ▼ line in a sketch,
- ▼ polyline segment,
- ▼ auxiliary axis,
- ▼ solid or surface edge.

Flat (planar) objects

- ▼ coordinate plane,

- ▼ auxiliary (construction) plane,
- ▼ Face of the body or surface.

To create angular dimensions use **Angular Dimension** command.

Select an objects with a cursor. two straight objects, two planar objects, or one straight and one planar object.

When creating dimensions between two straight objects, the dimension will be created in the plane running through these objects (Fig. 2.9.10,a). If the selected objects do not belong to the same plane, no dimension will be created.

When creating dimensions between two planar objects, the dimension will be created in the plane perpendicular to the intersection of these objects (Fig. 2.9.10,b). Dimensioning plane projections on the selected planar objects will be displayed as dashed lines.

The dimension between two planar objects can be moved along the intersection of these objects. To do this move the dimension's vertex handle with the mouse as necessary during dimension creation or editing.

When creating dimensions from a straight object to a planar object, the dimension will be created in the plane running through the selected straight object and its projection on the selected planar object (Fig. 2.9.10,c).

The projection lines will be displayed if **Show Connection Lines** option is turned on in dimension display settings (see Section 9.1.11.12 on p. 1736).

Fig. 2.9.10. Examples of the angle dimension:
a) between two edges, b) between two faces, c) between an edge and a face

The type of the newly created angular dimension will be determined by the system automatically. If necessary, you can change the dimensioning method chosen by the system using **Type** option group on the **Dimension** tab of the Property bar, including enabling dimensioning of angles greater than 180° (automatic choice of this option is disabled).

Set the position for the dimension line. To can do this by entering the extension line length in **Length** field (the length can be either positive or negative) or by resizing the handles at its ends using your mouse.

To mirror the display of dimension lines while keeping their lengths, click **Change Orientation** button.

If the dimension text should be placed on a leader shelf, follow the procedure described in Section 2.9.2.4.1 on p. 640.

If necessary, edit the dimension text (see Section 3.3.1.3 on p. 979) and specify the dimension display parameters (see Section 3.3.1.2 on p. 977) using Properties bar tabs.

2.9.2.7. Radial and Diameter Dimensions

The system allows for radial and diameter dimensioning in a number of ways. The settings for these two dimensioning types are mostly the same. The difference is in dimension type selection (see Sections 2.9.2.7.2 and 2.9.2.7.3).

2.9.2.7.1. Selection of objects for dimension creation

Radial and diameter dimensioning uses following object types:

- ▼ Circle (circular arc) in sketch
- ▼ Circular (arcuate) solid edge or surface edge
- ▼ Circular, conical, spherical or toroidal solid face or surface face.

When selecting a circle in a sketch, dimension is created in the sketch plane.

When selecting an edge, dimension is created in the plane of this edge (Fig. 2.9.11, a, b).

Fig. 2.9.11. Examples of part edge dimensioning:
a) radial, b) diameter

When selecting a face, dimension is created in the plane perpendicular to an axis of selected face (Fig. 2.9.12, a, b).

Fig. 2.9.12. Examples of part face dimensioning:
a) radial, b) diameter

The dimensioned circle will be displayed as a dash-dotted line with two points. The extension lines will be displayed as dashed lines.

The dimensioned circle and the extension lines will be displayed if **Show Connection Lines** option is turned on in dimension display settings (see Section 9.1.11.12 on p. 1736).

Dimension position can be free or fixed.

For free choice of dimension position, move the handle in the center of the dimensioned circle with your mouse along the face axis.

To fix the dimension position, turn on **Position** option on the **Dimension** tab of the Property bar and select the object to fix to: a point object or a planar object parallel to the dimensioning plane. The dimension will be created in the plane running through the fix object. Selecting this object again will cancel dimension position fixing.

An associative relation will be established between the dimension and the fix object. This relation causes the dimension to follow the fix object wherever it is moved.

2.9.2.7.2. Radial Dimension

To create radial dimensions use the **Radial Dimension** command.

Select an objects to set dimension (see Section 2.9.2.7.1).

The radial dimension can be created either from the circle center or not from the circle center. In both cases, the dimension line belongs to a line going through the center of the circle being dimensioned. The difference is the following. If a dimension is created from a center, then its dimension line length cannot be less than the radius. If a dimension is created not from a center, then its dimension line can be of an arbitrary length.

To select the desired dimensioning option use the **Type** option group on the **Dimension** tab of the Property bar.

Specify the dimension line position by moving the handle **p1** with your mouse (Fig. 2.9.13).

Fig. 2.9.13. Radial dimensioning with manually positioned dimension line

If necessary, edit the dimension text (see Section 3.3.1.3 on p. 979) and specify the dimension display parameters (see Section 3.3.1.2 on p. 977) using Properties bar tabs.

If the dimension text should be placed on a leader shelf, follow the procedure described in Section 2.9.2.4.1 on p. 640.

2.9.2.7.3. Diameter Dimension

To create diameter dimensions use the **Diameter Dimension** command.

Select an object to set dimension (see Section 2.9.2.7.1).

A dimension line can be Continuous or Broken. The desired option can be selected in the **Type** option group on the **Dimension** tab of the Property bar.

A broken dimension line projects (extends) beyond the circle center by the distance equal to 1/5 of the radius, but not less than by the distance set in this document for the dimension line projection (extension) beyond the text. This value is specified during setup dimension parameters in the current model (see 9.2.7.2.2 on p. 1836).

Specify the dimension line position by moving the handle **p1** with your mouse (Fig. 2.9.14).

Fig. 2.9.14. Diameter dimensioning with manually positioned dimension line

If necessary, edit the dimension text (see Section 3.3.1.3 on p. 979) and specify the dimension display parameters (see Section 3.3.1.2 on p. 977) using Properties bar tabs.

If the dimension text should be placed on a leader shelf, follow the procedure described in Section 2.9.2.4.1 on p. 640.

2.9.2.7.4. Dimensioning Features

Dimensioning of a conical, spherical or toroidal face has the following features.

Conical face

The conical face diameter dimension is created in the plane perpendicular to the face axis (cone axis) and running through the point where the face was selected (Fig.2.9.15).

Fig. 2.9.15. Conical face diameter dimensioning example

The dimension will correspond to the radius (diameter) of the cone's section by the dimensioning plane. When the dimension is moved along the cone axis, it will update as the cone section radius (diameter) changes.

If the dimension position is fixed (see Section 2.9.2.7.1 on p. 644), then the dimension will correspond to the radius (diameter) of the cone section by the plane running through the fix object. The fix object can be a point object or a planar object perpendicular to the cone axis.

Spherical Face

Spherical face diameter dimension is created in the plane running through the center of the sphere and the point where the face was selected (Fig.2.9.16). The initial plane position is chosen by the system. If necessary, you can change the dimensioning planes position by moving the handle **p1** with your mouse.

Fig. 2.9.16. Spherical face diameter dimensioning example

If the dimension position is fixed (see Section 2.9.2.7.1 on p. 644), following options of its position will be available:

- ▼ With reference to a point object— in the plane running through the sphere center and the selected point object; the dimensioning plane position will be determined by the system.
- ▼ With reference to a planar object— in the plane running through the sphere center parallel to the selected flat object.

Toroidal face

The toroidal face diameter dimension is created in the plane perpendicular to the face axis (torus circular axis) and running through the point where the face was selected (Fig.2.9.17).

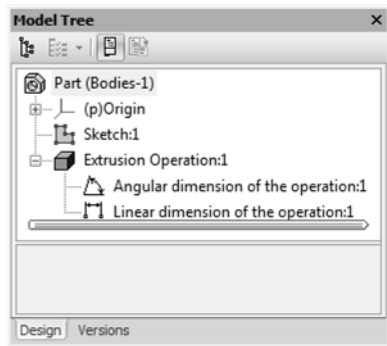

Fig. 2.9.17. Toroidal face diameter dimensioning example

The fix object (see Section 2.9.2.7.1 on p. 644) can be any point object or a flat object perpendicular to the torus circular axis.

2.9.2.8. Derivative dimensions

Dimensions of sketches and dimensions of operations can be represented in the form of layout elements. As a result, **derivative dimensions** corresponding to dimensions of sketches and operations will appear in the Model Window. In the Design Tree, derivative dimensions are displayed as subordinate to sketches and operations (see Fig. 2.9.18).

a)

b)

Fig. 2.9.18. Derivative dimensions:
a) in the Design Tree, b) in the Model Window

In order to present dimensions of sketches and operations as layout elements, perform the following steps.

1. Call the **Operations — Layout Elements — Derivative Dimensions** command. The respective command calling button is located on the panel **Layout Elements**.
2. In the Design Tree, select objects the dimensions of which should be displayed as layout elements or specify any objects' primitive in the Model Window. a face, edge, or vertex.

Objects may be also selected before the command selection.

Specified objects are highlighted in a certain color and their names appear on the **List of Objects** bar. To cancel object selection, re-select it.

3. Enable the **Dimensions with zero value** option if you need to create derivative dimensions for dimensions of operations with zero value.

4. In order to change objects the dimensions of which should be displayed as layout elements, click the **Re-select** button on Special Control Panel and repeat object selection.
5. Having finished selection of objects, click the **Create Object** button on the Advanced Control panel.

Dimensions of the sketch with no created variables cannot be presented as layout elements.

Derivative dimensions of selected objects appear in the model window or in the Design Tree. The default color of dimensions displayed in the window is violet.

Derivative dimensions for dimensions with zero value are displayed only in the Design Tree. These derivative dimensions are not displayed in the model window.

Controlling dimensions of sketches and operations presented as layout elements retain their type, i.e. they remain the guiding ones. If the value of such a dimension is changed, the model will be rebuilt. The derivative dimension value is changed in the dimension value setting dialog (Figure 2.9.2.2.1 on p. 634).

The derivative dimensions can be transferred to a drawing when creating a model's associative views in it (see Section 3.6.1.2 on p. 1208). Dimensions transferred to the drawing are **projection designations**. Work with projection designations is described in Section 3.6.3.5 on p. 1226.

2.9.2.8.1. Specifics of Working with Derivative Dimensions

If a chamfer is built using a side and a 45° angle, a single linear derivative dimension will be created (in accordance with the standard). The dimension text of the dimension contains values of the chamfer's side and angle, for example, 5x45°. If necessary, you can create two derivative dimensions (linear and angular) for this chamfer. For this, do the following.

1. Select the derivative dimension of the chamfer in the Design Tree or in the model window and call the **Edit** command from the context menu.
2. Call the dialog for the dimension's text entry. For this purpose, click inside the **Text** field on the **Dimension** tab of the Property bar.
3. Clear the **Text after** field and close the dialog by clicking **OK**.
4. In order to finish editing dimensions, click the **Create Object** button on the Advanced Control panel. The dimension text of the edited dimension will contain only the chamfer side's value.
5. Call the **Derivative dimensions** command.
6. Select a chamfer in the Design Tree or in the Model Window:
7. Click the **Create Object** button. The angular derivative dimension will be added to the linear derivative dimension of the chamfer in the Design Tree or in the Model Window.

2.9.2.9. Editing derivative dimensions

You can edit the display of a derivative dimension: specify new drawing parameters and edit the dimension text.

Besides that, you can edit location of the specified derivative dimensions, i.e. specify the required plane (or a flat face) in which the dimensions will be positioned.

Editing of the derivative dimension display is described in Section 2.9.2.9.1 on p. 650; derivative dimensions positioning is described in Section 2.9.2.9.2 on p. 651.

2.9.2.9.1. Editing derivative dimension display

When editing the display of a derivative dimension, you can modify its dimension text and specify new drawing parameters.

In order to change displaying of the derivative dimension, select it in the Design Tree or in the Model Window and call the **Edit** command from the context menu.

Parameters, **Deleted**, **Properties** tabs will appear in the Property Bar.

Controls of the **Dimension** tab are described in Table 2.9.1, description of the **Parameters** tab can be found in Table 3.3.3 on p. 977.

Controls located in the **Properties** tab allow defining name of dimension in the Design Tree and color of drawing of dimensional lines.

Tab. 2.9.1. Control elements on the **Dimension** tab

Element	Description
Object	This field displays the name of object (sketch or operation), the dimensions of which are presented as layout elements (derivative dimensions).
Parameter	This field displays the name of the sketch's dimension or operation's parameter represented as a layout element (derivative dimension).
Length*	<p>The field allowing to define the length of derivative dimension leaders. By default, the field contains the value of the length of the leaders' dimension.</p> <p>To change default value, enter required length value from the keyboard or define it using the counter (the value may be both positive and negative).</p> <p>The leaders' length can also be changed using handles at the end points of the dimension line.</p> <p>When moving one of the handles using the mouse, the value of the length will be automatically defined and entered in this field.</p>
Text**	This is the field for calling the Enter Dimension Text dialog, in which you can specify the desired dimension value and set up its format (see Section 3.3.1.3 on p. 979).

Tab. 2.9.1. Control elements on the **Dimension** tab

Element	Description
Type***	The group of switches allowing to specify the type of the dimension line in a diameter dimension: <ul style="list-style-type: none"> ▼ full or with a break – for the diameter dimension; ▼ from center or not from center – for the radial dimension.

* It is available in the Property bar when editing a linear or angular dimension.

** It is available in the Property bar when editing a linear, diameter or radial dimension.

*** It is available in the Property bar when editing a diameter or radial dimension.

In order to finish editing the derivative dimension, click the **Create Object** button on the Advanced Control panel.

You can cancel dimension editing by pressing <Esc> or by clicking the **Cancel Command** button.

2.9.2.9.2. Locating the derivative dimensions

Immediately after their creation, the derivative dimensions are positioned as follows:

- ▼ the derivative dimension, that corresponds to the sketch's dimension, is positioned in the sketch's plane,
- ▼ the derivative dimension, that corresponds to the operation's dimension, is positioned in the plane, which is automatically defined by the system depending on the type of dimension and of the object created by the operation.

The plane in which a derivative dimension is located immediately after its creation is called the **initial plane**.

You can position one or several derivative dimension in a different plane by specifying the **base plane**. The following can be used as a base plane:

- ▼ Coordinate or auxiliary plane
- ▼ planar face.

The derivative dimension changes its position (it is positioned in the base plane), if the positioning conditions are met (see Section 2.9.2.9.3 on p. 651). If the conditions are not met, the derivative dimension will not change its position, and the respective message will appear on the screen.

If necessary, you can cancel changes after the dimension positioning in the base plane, and the dimension will be positioned in the initial plane.

Procedure for positioning of derivative dimensions is described in Section 2.9.2.9.4 on p. 652.

2.9.2.9.3. Prerequisites for positioning the derivative dimension in the base plane

- ▼ The derivative dimension is located in the base plane, if the plane is parallel to its initial plane.
- ▼ Besides that, the following positioning options are available for some types of dimensions:

- ▼ A linear dimension is positioned in the base plane, if the plane intersects its initial plane along the line which is parallel to the dimension line.
- ▼ The derivative dimension, corresponding to the *Wall Thickness* or *Slope Angle* extrusion operation's parameter, is located in the base plane, if this plane intersects the section and perpendicular to it in the intersection point.
- ▼ The derivative diametric dimension can be located in the base plane if the plane is perpendicular to the initial plane. In this layout, diameter dimension converts to linear.

2.9.2.9.4. Procedure for positioning the derivative dimensions

In order to change the plane, in which derivative dimensions are positioned, or cancel changes and position the dimensions in their initial planes, perform the following steps.

1. Call the **Editor — Position derivative dimensions** command. The respective command calling button is located on the **Layout Elements** bar.
2. Create a set of derivative dimensions, locations of which need to be changed. For this purpose, specify the required derivative dimensions in the Design Tree or in the Model Window:

Derivative dimensions can be selected before calling the command.

Specified dimensions are highlighted in a certain color and their names appear on the **List of Dimensions** bar. Reselecting a dimension cancels its selection.

- ▼ In order to select all derivative dimensions of the model at once, click the **Select all dimensions** on the **List of Dimensions** bar.

- ▼ To change dimensions, click the **Reselect** button on the Special Control Panel and re-select dimensions.

- ▼ In order to delete a dimension from the set, highlight its name in the list of dimensions on the **List of Dimensions** bar and click the **Delete** button.

3. Specify the plane for location of the set's dimensions using the **Base plane** group of switches.

- ▼ In order to locate the dimensions of a set in their initial planes, enable the **Autodefine** switch.

- ▼ In order to locate the dimensions of a set in a new plane, enable the **Specify manually** switch. Then, specify the required plane or a flat face in the Model Window. The specified object is highlighted by a certain color, and its name is displayed in the **Plane** field of the Property Bar.

In some cases, when positioning a derivative dimension there are a number of placement scenarios after a new plane is specified. An example is the placement of derivative dimension in the *Chamfer* operation when a new plane intersects the rib on which the chamfer is built and is perpendicular to it.

If there are several placement scenarios, the **Next object** and **Previous object** become available on the Advanced Control Panel. They are used to select the desired scenario.

4. Having set the parameters of locating dimensions, click the **Create Object** button on the Advanced Control panel.

Specified dimensions are located in accordance with the settings applied.

- ▼ If the plane for location of dimensions is selected automatically, each dimension of the set will be located in its initial plane, and the names of all dimensions of the set are deleted from the **List of Dimensions** bar.
- ▼ If the base plane is selected, dimensions of the set are located in the selected plane, lines of dimension projections and lines conditionally indicating objects with dimensions are displayed on the screen with connection lines. Names of dimensions are deleted from the **List of Dimensions** bar.

If, after clicking the **Create object** button, the names of dimensions remain on the **List of Dimensions** bar, it means that these dimensions cannot be located in the selected plane. The respective message will be displayed, and dimensions will remain in their current base planes (or initial planes). These dimensions will remain highlighted. You can assign another base plane to them.

By calling the **Locate derivative dimensions** command once, you can change location planes for any number of dimensions.

You can cancel locating dimensions by pressing <Esc> or by clicking the **Cancel Command** button.

Note that connection lines of dimensions are displayed only if the **Connection Lines** option is enabled in the dialog for dimension and designation display setup (see Section 9.1.11.12 on p. 1736).

2.9.3. Designations

The system allows to attach the following symbols:

- ▼ surface finish symbol,
- ▼ Base surface symbol
- ▼ Auxiliary extension line
- ▼ Stamping symbol leader
- ▼ Marking symbol leader
- ▼ Item symbol leader (only in assembly models),
- ▼ Form tolerance symbol.

The symbols in the model have the following features.

- ▼ The symbols get an associative relation to the objects selected during their creation. This relation causes each symbol to relate to a particular object in the model at all times.
- ▼ Every symbol exists in a plane that is called **symbol plane**. The symbols always remain within their planes, i.e. whenever the model is rotated, they will rotate correspondingly. If the model is rotated so that the symbol plane becomes perpendicular to the screen plane, then the symbol will not be displayed.
- ▼ If the symbol plane is not perpendicular to the screen, the symbol will always be displayed so that its text can be read from left to right.

To insert a symbol, use the appropriate symbol command, select the object(s) to which the symbol should be attached in the Model window, and adjust the symbol settings.

Common symbol creation methods are described in Section 2.9.3.1, while special techniques for creating particular symbols are described in Sections 2.9.3.2– 2.9.3.8.

For surface finish symbols and datum symbols, automatic creation is available. Automatic creation is on by default, which is indicated by a depressed **Object Autocreation** button on the Advanced Control Panel.

For other symbols, you will have to confirm their creation manually using **Create Object** button.

The automatic and manual object creation is detailed in Section 1.4.2.10 on p. 93.

If necessary, you can insert more than one symbol of the same type in one insert symbol command. To do this, without exiting the command, select the objects one by one which the symbols should be attached to.

The created designations will appear in the model window, while their icons will appear in the Design Tree.

To finish current command, click **Interrupt Command** button on the Advanced Control Panel.

To rotate the model so that the new symbol plane is parallel to the screen plane, without interrupting the insert symbol command. Use **Normal To...** command in **Orientation** button menu (see Section 2.1.3.2 on p. 121)

The 3D model operation mode doesn't support vector fonts including the KOMPAS-3D supplied fonts GOST type A (plotter), GOST type B (plotter), Symbol type A (plotter), Symbol type B (plotter) therefore you shouldn't use them for text included into designations.

Symbols can sometimes disturb from viewing the model. To hide a symbol, select it and use **Hide** context menu item.

Hidden symbols will not be transferred to the drawing when associative views of the model are created in it.

To make a hidden symbol visible, select it in the Design Tree and use **Show** context menu item.

You can hide all symbols at once using **View— Hide— Symbols** command. This will prevent both existing symbols and new symbols in the model from being displayed. To make all symbols visible, use the same command again. This will not display those symbols that were hidden individually.

If the element which the symbol was attached to is removed from the model in the process of editing (e.g. the edge to which the leader was attached is filleted), the symbol remains where it was. Therefore, to prevent such "loose" symbols from appearing in the model, it is recommended that the symbols are inserted only once the model shape is finished.

KOMPAS-3D uses the default symbol settings that are most commonly used in design documentation. If necessary, you can change these values. Parameters of designations setup is described in Section 9.2.7.3 on p. 1839.

2.9.3.1. Common Symbol Creation Methods

2.9.3.1.1. Specifying Symbol Plane Position

The symbol plane is parallel to the base plane. One of the coordinate planes is used as a base plane.

Initially, the base plane is selected automatically by the system depending on model position with respect to the screen plane. If necessary, you can select another base plane or move the symbol plane parallel to itself.

To select another base plane, choose the desired plane in the **Base Plane** drop-down list on the **Symbol** tab of the Property bar (Fig. 2.9.19). You can also use context menu item **Set Plane XY/ZX/ZY to the base plane**.

Fig. 2.9.19. Property bar during leader construction

By default, the symbol plane will run through the point where the object which the symbol is attached to was selected (or through the object itself if it is a point object). If necessary, you can move the symbol plane from its default position.

When creating a surface finish symbol or a datum symbol, this opportunity will only be available if automatic object creation is disabled and only once the symbol is generated (symbol insertion point is specified for a surface finish symbol or the point determining the position of the text box and the starting point of one branching is specified for a datum symbol).

To move the symbol plane, click **Position** button on the **Symbol** tab of the Property bar. The ghost of the designation symbol's plane is displayed.

Symbol plane offset can be set freely or fixed to match an object existing in the model.

- ▼ For free positioning of the symbol plane, move its ghost's handle with your mouse. The ghost will move so that the symbol plane remains parallel to the base plane and all branching starting points remain on the object(s) which the symbol is attached to.

If the symbol plane cannot be moved (e.g., because the object which the symbol is attached to is either a point or an edge parallel to the base plane), the ghost will remain in its place.

- ▼ To fix the symbol plane position, select the object to fix to. The symbol plane will run through that object. The fix object can be any point or straight or planar object in the model that is in such position that makes it possible to draw a plane through it parallel to the base plane and

crossing the object which the symbol is attached to. Selecting the fix object again will cancel symbol plane position fixing.

An associative relation will be established between the symbol plane and the fix object. This relation causes the symbol plane to follow the fix object wherever it is moved.

If the symbol plane is fixed, then it will be impossible to select another base plane (base plane list will be unavailable). You will need to unfix the symbol plane to be able to select another base plane.

2.9.3.1.2. Adding and Removing Branchings

Leaders, marking and stamping symbols, ref.no. leader and geometric tolerances can have more than one branching.

All branchings of the same symbol shall belong to that symbol's plane, i.e. points belonging to the symbol plane shall be specified as the second and subsequent starting points of the branching.

When specifying start points of additional branches, when the cursor passes above a body (or a surface), intersecting with the symbol plane, the line of intersection of the body (plane) with the symbol plane is displayed as a dashed line. Faces of solids and surfaces can only be selected at points belonging to that line. Whenever the mouse cursor is hovered over this line, the *Point on Line* snap name and a face icon will be displayed.

To add the branching to the symbol, move the cursor to the required point of this branching start (on the line of intersection of the face and symbol plane) and click the mouse, when the *Point on Curve* snap name appears beside it.

The starting point of a branching can be a 3D point in the symbol plane, as well as a point belonging not to a face, but, for example, to a 3D line, auxiliary axis, etc. An indicator of whether the point can be the starting point of a branching is the *Nearest Point* snap name and the icon of the object which this point belongs to appearing next to the mouse cursor when it hovers over this point.

The symbol is considered related to an object if the symbol's branching starting points belong to that object. List of objects which the symbol relates to can be found in the **Objects List** pane on the **Symbol** tab of the Property bar (see Fig. 2.9.19 on p. 655).

When an object is selected in the list, its corresponding branching is highlighted in the Model window.

To delete a branching, select it in the list and press *Delete* or click **Delete** button on the **Objects List** toolbar.

2.9.3.2. Surface Finish

The surface finish symbol can be attached to the following objects:

- ▼ solid or surface face,
- ▼ solid or surface edge,

- ▼ 3D polyline segment,
- ▼ dimension,
- ▼ marking.

To create the symbol use the **Face Finish** command.

Select the object which the surface finish symbol will be attached to.

To select another object, click **Select Other** on the Special Control Panel and select the desired object.

After calling the command, a designation ghost will appear. The ghost will appear in the symbol plane. If necessary, you can move the symbol plane (see Section 2.9.3.1.1).

If a dimension or a symbol is selected as the object which the surface finish symbol should be attached to, then the surface finish symbol will be created in that object's plane. You will not be able to change the plane's position.

By default a surface finish symbol is created, whose machining type is not specified. Also, **Without Machining Type** option will be enabled in the **Type** group. To create a finish symbol for a surface generated with or without material removal, set the appropriate option in this group.

Enter the text and configure symbol drawing (see Section 3.3.7.3.1 on p. 1022 and Section 3.3.7.3.2 on p. 1023).

By default, surface finish symbol will be created on leader shelf.

Select the start point of Leader Bend.

Fig. 2.9.20. An example of applying a finish symbol

The structure of the surface finish symbol is defined by GOST2.309-73 (see Fig.3.3.48 on p. 1021).

You can select the structure used in the current model during surface finish symbol setup in the current model (see Section 9.2.7.3.12 on p. 1842). By default, in new models designations of finish are created according to the change in GOST2.309–73.

Without leaving the command, you can create several surface finish symbols. Selected symbol type and the generated text will be saved.

2.9.3.3. Datum

Datum symbols can be attached to following object types:

- ▼ faces of surfaces and bodies,
- ▼ Edges of surfaces and solids
- ▼ dimensions,
- ▼ Auxiliary axes and planes,
- ▼ 3D Curves.

You can create datum surface symbols using **Datum** command.

Select a surface target for a datum symbol.

To select another object, click **Select Other** on the Special Control Panel and select the desired object.

Once the object is selected, a symbol ghost will appear. The middle point of the base of the triangle designating the datum will match with the point at which the object was selected. The ghost will appear in the symbol plane. If necessary, you can move the symbol plane (see Section 2.9.3.1.1).

If a dimension or a symbol is selected as the object which the datum symbol should be attached to, then the datum symbol will be created in that object's plane. You will not be able to change the plane's position.

By default, a datum symbol, perpendicular to the selected reference object, is created. Also, **Perpendicular to Base Object** option will be enabled in **Type** group on the Property bar. If a pitched symbol should be created, set the **Arbitrary Orientation** option.

In the **Text** field on the Property Bar, the letter is displayed that is suggested by the system as the Enlarged Detail.

By default, **Auto-sorting** option is on: in this way all datum symbols are assigned alphabetical characters automatically as they are created, thereby preventing duplicate designations. If **Auto-sorting** is on, **Text** field will be unavailable. If you need to enter the datum character manually, disable the **Auto-sorting**. **Text** field will be enabled; however, duplicate character control will be deactivated.

If **Auto-sorting** is then re-enabled, the manually entered characters will be replaced with automatic characters.

Select the point defining the text frame position.

Fig. 2.9.21. An example of applying a datum symbol

2.9.3.4. Leader

Leaders can be attached to following object types:

- ▼ solid or surface face,
- ▼ coordinate plane,
- ▼ auxiliary (construction) plane,
- ▼ sketch point,
- ▼ 3D point,
- ▼ 3D line vertex,
- ▼ a sketch line,
- ▼ 3D polyline segment,
- ▼ a 3D curve,
- ▼ solid or surface edge,
- ▼ coordinate axis,
- ▼ auxiliary axis,
- ▼ dimension,
- ▼ marking.

You can create a custom leader using **Leader** command.

Select the object which the first branching of the leader will point at. The first branching will start from the point at which the object was selected.

Select the start point of a leader shelf.

The symbol ghost will appear. The ghost will appear in the symbol plane. If necessary, you can move the symbol plane (see Section 2.9.3.1.1 on p. 655).

If a dimension or a symbol is selected as the object which the leader should be attached to, then the leader will be created in that object's plane. You will not be able to change the symbol plane's position.

To specify starting points for additional branchings, select the points belonging to the symbol plane. For details on how to add and remove branchings, see Section 2.9.3.1.2 on p. 656.

Enter the text and configure leader drawing (see Section 3.3.7.4.1 on p. 1024 and Section 3.3.7.4.2 on p. 1025).

Edit Points button on the Advanced Control Panel allows changing the leader configuration (see Section 3.3.7.4.3 on p. 1027).

To fix the symbol, click **Create Object** button.

Fig. 2.9.22. Example of creating a leader

2.9.3.5. Stamping Symbol

To attach stamping symbol you can use faces of bodies and surfaces.

You create a leader for a stamping symbol using **Stamping Symbol** command.

Select the object which the first branching of the leader will point at. The first branching will start from the point at which the object was selected.

Specify the point determining the stamping symbol position.

The symbol ghost will appear. The ghost will appear in the symbol plane. If necessary, you can move the symbol plane (see Section 2.9.3.1.1).

To specify starting points for additional branchings, select the points belonging to the symbol plane. For details on how to add and remove branchings, see Section 2.9.3.1.2 on p. 656.

In the **Text** field on the Property Bar the text is displayed that is suggested by the system as the Stamping Symbol. If needed, you can change the contents and the display style of the text (see Section 3.3.7.5.1 on p. 1030).

Configure stamping symbol drawing (see Section 3.3.7.5.2 on p. 1031).

Edit Points button on the Advanced Control Panel allows changing the leader configuration (see Section 3.3.7.4.3 on p. 1027).

To fix the symbol, click **Create Object** button.

Fig. 2.9.23. An example of applying a stamping mark

2.9.3.6. Marking Symbol

Faces of bodies and surfaces may be used for marking symbols.

You can create a leader for a marking symbol using **Marking Symbol** command.

Select the object which the first branching of the leader will point at. The first branching will start from the point at which the object was selected.

Specify the point determining the marking symbol position.

The symbol ghost will appear. The ghost will appear in the symbol plane. If necessary, you can move the symbol plane (see Section 2.9.3.1.1).

To specify starting points for additional branchings, select the points belonging to the symbol plane. For details on how to add and remove branchings, see Section 2.9.3.1.2 on p. 656.

In the **Text** field on the Property Bar the text is displayed that is suggested by the system as the Marking Symbol. If needed, you can change the contents and the display style of the text. This is done in the same way as when creating a stamping symbol in a graphic document (see Section 3.3.7.5.1 on p. 1030).

Using the **Arrow** list on the **Options** tab of the Property bar you can select the type of the arrow of the leader line. If this arrow type must be used in the Marking Symbols up to the end of the current working session, enable the option **By default**.

Edit Points button on the Advanced Control Panel allows changing the leader configuration (see Section 3.3.7.4.3 on p. 1027).

To fix the symbol, click **Create Object** button.

Fig. 2.9.24. An example of applying a marking symbol

2.9.3.7. Ref.No. Leader

The following objects can be used to designate a position:

- ▼ solid or surface face,
- ▼ solid or surface edge.

To create a leader line to designate Ref.No. call the **Ref. No.Designation** command.

Select the object which the first branching of the leader will point at. The first branching will start from the point at which the object was selected.

Select the start point of a leader shelf.

The symbol ghost will appear. The ghost will appear in the symbol plane. If necessary, you can move the symbol plane (see Section 2.9.3.1.1).

In the **Text** field on the **Symbol** tab of the Properties bar, the system-generated text is suggested — the reference number. If needed, you can change the number and its display style, as well as create additional shelves with reference numbers. This is done in the same way as when creating a position symbol in a graphic document (see Section 3.3.7.7.1 on p. 1033).

To specify starting points for additional branchings, select the points belonging to the symbol plane. For details on how to add and remove branchings, see Section 2.9.3.1.2 on p. 656.

Edit Points button on the Advanced Control Panel allows changing the leader configuration (see Section 3.3.7.4.3 on p. 1027).

To fix the symbol, click **Create Object** button.

An example of applying a position reference number.

2.9.3.8. Geometric Tolerance

Geometric tolerance symbol can be attached to the following objects:

- ▼ solid or surface face,
- ▼ coordinate plane,
- ▼ auxiliary (construction) plane,
- ▼ solid or surface edge,
- ▼ 3D polyline segment,
- ▼ auxiliary axis,
- ▼ dimension,
- ▼ marking.

You can create a geometric tolerance symbol using **Geometric Tolerance** command.

Select the object which the symbol will be attached to.

Select the point that will determine the marquee box position. By default, the bottom left corner of the border is placed in the selected point. Also, in the **Anchor Point** list, the **Bottom Left** option is selected. To change the position of the frame relative to the insertion point, expand the specified list and select the desired line.

To make the box appear vertical, turn on **Vertical** option on the Property bar.

The marquee box ghost will appear. The ghost will appear in the symbol plane. If necessary, you can move the symbol plane (see Section 2.9.3.1.1).

If a dimension or a symbol is selected as the object which the symbol should be attached to, then the geometric tolerance symbol will be created in that object's plane. You will not be able to change the symbol plane's position.

Generate the tolerance table (see Section 3.3.7.13.1 on p. 1046).

To create a branching with an arrow or a triangle, click the appropriate button on the Special Control Panel and select the branching starting point in the symbol plane. End point of all branches is the basic point (point of the frame in **Basic Point**) list.

To finalize a branching creation, click the respective button on the Special Control Panel.

For details on how to add and remove branchings, see Section 2.9.3.1.2 on p. 656.

To create the next branching click the appropriate button again.

Edit Points on the Special Control Panel makes it possible to adjust the configuration of branchings. Once it is clicked, the points will be displayed as black squares and circles. Move the cursor to any handle. Shape of the cursor will change: it will turn into a four-sided arrow. You can move the handles by dragging them with your mouse.

To exit the mode of editing the handle positions, release the **Edit Points** button.

To fix the designation, click **Create Object** button.

Fig. 2.9.25. Example of entering of geometric tolerance and location of surface

2.9.4. Cosmetic Thread

In KOMPAS-3D models, threads are created not as helical surfaces, but as symbols: wireframe cylinders or cones. To build a symbol of thread in a model, perform the following actions.

1. Call the command **Cosmetic Thread**.

On the Properties Bar controls will appear for setting thread parameters.

2. Specify the base item of the thread: a cylindrical or conical face.

A ghost of a symbolic thread depiction will appear in the model window.

The starting border of the thread is determined automatically as you specify the base object. If you need to change starting border, activate the **Initial Border** switch, then specify on the Design Tree the surface, face, or plane for which you want to plot the thread.

3. Set thread standard, diameter and pitch. This is done the same way, as when building a threaded hole (see p. 3 and 4 Section 2.3.9.1.4 on p. 212).

For non-standard threads, the **Auto Define Thread Diameter** option is available. Enable the automatic diameter determination option using the dimensions of the object to be threaded. The automatically calculated diameter value is displayed in the field **Thread Diameter**. Set thread pitch.

4. Set thread length. To do this, use the **Thread length** group of switches. The following methods are available:

- ▼ **To specified length:** thread length is defined by the specified distance. Enter thread length value in the **Thread Length** field.

- ▼ **To finish border:** thread length is determined automatically using the end limit of the thread. If you need to automatically change a certain thread end limit, activate the **Final Border** and specify the desired surface or rim.

As a thread starting/end limit, a rim of the thread reference object face or a rim of a co-axial conical (countersink surface) or toroidal (rounding surface) face must be specified. The edge that can be used is highlighted when the mouse pointer hovers over it.

Turn on the **Fitting** option if you need to change the geometry of the base object of the thread (see Section 2.9.4.1 on p. 665).

5. If necessary, use the following additional functionalities.

- ▼ Copying existing thread parameters. For that, call the command **Thread by sample** by clicking the corresponding button on the Advanced Control Panel or from the context menu. Select the thread to copy parameters from in the model window or on the Design Tree. The thread being created will have the same parameters as the template thread. Edit the parameters if necessary.

- ▼ Cancel selection of all objects. To do this, click the **Select other** button on the Advanced Control Panel.

6. Having finished adjustment, click **Create Object** button to fix the cosmetic thread in the model.

The Model window will show a wireframe cylinder or cone (Fig. 2.9.26) representing the tread, and the Model Tree will show a thread icon. Next to the cosmetic thread on the Tree, thread designation and a *Symbolic depiction message* (for non-standard thread a *Symbolic thread depiction message* is used).

If 'fitting' was used when creating symbolic thread depiction, its icon appears on the Model Tree as a subordinate object for the thread depiction. You can turn on/off 'fitting' without entering thread editing mode using the command **Fitting** on the context menu of the thread on the Model Tree.

Building symbolic depiction of standard conical thread has the following special features:

- ▼ Creating an object is possible only by using fitting.
- ▼ Thread can be plotted only for a given depth. Maximum depth depends on the hole dimensions and is set by the standard.

Fig. 2.9.26. Cosmetic Thread on Nipple part

Note that a cosmetic thread is always shown in a model in its entirety. For example, suppose that the **Trim by Surface** command cuts off or slashes through a feature which bears a thread. In this case, the cosmetic thread will be displayed in the model in its entirety, even though the surface (or a portion thereof) that bears the thread is not shown.

When creating associative model views in drawings, which contain cosmetic threads, the latter can also be drawn on the views (see Section 3.6.1.3.3 on p. 1213).

2.9.4.1. Using fitting

Fitting is used if you need to change the geometry of the base object of the thread to match the selected nominal diameter. In the process, for a cylindrical surface – the diameter is 'adjusted' to match thread parameters (Fig. 2.9.27), for a conical surface – diameter in the main plane, and the cone angle.

Turning fitting on and off is done using the **Fitting** option on Properties Bar, when creating or editing cosmetic thread.

Fig. 2.9.27. Example of a thread in a simple hole:
a) without fitting, b) with fitting

When fitting a hole with a countersink (chamfer or rounding) the depth of countersink is changed. To 'fit' the depth of countersink, enable additional fitting switch **Offset 1**. This allows offsetting the starting limit of the threaded section to the initial position and keep the initial depth of the countersink (Fig. 2.9.28).

Fig. 2.9.28. Example of a thread in a countersinked hole:
 a) without fitting, b) with fitting, **Offset 1** disabled (the dashed line designates the depth of countersink prior to fitting), c) with fitting, **Offset 1** enabled

When fitting a hole with the non-flat end face, the length of threaded section changes. To 'adjust' this length, enable the additional fitting switch **Offset 2**. This allows offsetting the end limit of the thread reference object leaving unchanged the length of the section of the surface, on which the thread is created, see Fig2.9.29.

Fig. 2.9.29. Example of creating a thread in a hole with non-flat end face:
 a) without fitting, b) with fitting, **Offset 2** disabled (the dashed line designates the depth of countersink prior to fitting), c) with fitting, **Offset 2** enabled

For a rod with external thread, with a chamfer or rounding at the starting/end limit of the thread, additional fitting is done similar to a hole.

2.10. Tolerances. Model recalculation based on tolerances

2.10.1. General Information

All objects in the model are created by performing operations. If numeric parameters of an operation are expressed in linear or angular values, tolerances may be assigned for the parameter values. In addition, you may assign tolerances for sketch dimensions. For more information about dimensions of sketches and operations, see Section 2.9.2.2 on p. 632; for tolerances and their purpose, see Section 2.10.2 on p. 667.

When working with a model, you can use **model dimensions recalculation mode**. This mode is used to recalculate model dimensions taking into account the assigned tolerances. Model dimensions calculation is done in accordance with the current recalculation.

KOMPAS-3D supports three system recalculations of dimensions: **to middle part of the tolerance field, by upper limit and by lower limit**. It is also possible to create **user** recalculations.

For more information on model dimensions recalculation mode and working in this mode see Section 2.10.3 on p. 671.

2.10.2. Tolerances

KOMPAS-3D supports assigning tolerances for sketch dimensions and values of numeric parameters of an operation for which the following conditions are met:

- ▼ the parameter is expressed in linear or angular values;
- ▼ the parameter variable is not an information variable (for details on informational variables see Section 7.1.1.2.1 on p. 1570).

It is possible to assign **general** and **individual** tolerances.

A tolerance is assigned automatically based on settings (see Section 9.2.7.2.10 on p. 1838). These settings determine:

- ▼ objects, dimensions, and parameters that should have the tolerance;
- ▼ the value of the individual tolerance for dimensions of different types: linear, angular, diameter, radial; dimensions that no value of an individual tolerance has been assigned to have a general tolerance.

Conditions for using a general tolerance in a model and its setup are described in Section 2.10.2.1 on p. 668.

If necessary, when creating or editing an object the user can manually enable/disable a tolerance for a dimension (parameter), modify the value of the individual tolerance, change a general tolerance to an individual one and back (see Section 2.10.2.2 on p. 669).

The individual tolerance is displayed both in the Variables window and in the dimensional text of the sketch dimensions and the dimensions corresponding to the operation parameter (for information on the dimensions of sketches and operations, see Section 2.9.2.2 on p. 632; on

tolerances in the Variables window, see Section 7.1.4.2 on p. 1587). General tolerances are shown in the Variables window.

If the model requires a rebuild, the Variables window may display incorrect maximum values of parameters or dimensions calculated using the common tolerances. To view the correct values, rebuild the model.

Figure 2.10.1 shows an example display of individual tolerances in sketch dimensions and operation dimensions during extrusion creation.

Fig. 2.10.1. Displaying individual tolerances during extrusion creation

Tolerances can only be assigned to parameters of those operations that have been created directly in the current model (for example, for parameter values of a cut extrusion or mating element, etc). Tolerances for parameter values of operations performed in a component must be assigned when working with this component.

Common and individual tolerances used in the model **dimensions recalculation mode**. More on the mode, see Section 2.10.3 on p. 671.

Individual tolerance can be assigned for control and information sketch dimensions (with or without a variable). However, the model dimensions recalculation mode uses only the controlling sketch dimensions that have a variable.

2.10.2.1. General tolerances

General tolerances in KOMPAS-3D are set for four precision classes based on GOST 30893.1-2002 (ISO 2768-1-89).

Enabling the use of common tolerances and selection of the desired accuracy class is done in the general tolerances configuration dialog (see Section 9.2.7.4.9 on p. 1854). By default, the use of common tolerances is On.

A general tolerance is assigned automatically for all dimensions and parameters that can have a tolerance, except for:

- ▼ a dimension or parameter with an individual tolerance or the sign *Nominal (framed)* (see Section 2.10.2.2 on p. 669 for more information),

- ▼ an angular parameter of a 3D curve, point or construction plane.
- ▼ a linear dimension or a linear parameter whose absolute value lies in the range of [0...0.5),
- ▼ angular parameters with the value of 0,
- ▼ angular parameters of a rotation operation with the value of 360.

Setting up the maximum deviations for parameter values and dimensions on common tolerances is performed using data contained in the **deviations file** (see Section 2.10.2.1.1 on p. 669).

According to the standard, maximum tolerances for blunt edge parameters differ from other linear parameter deviations for the same value range and accuracy class. In KOMPAS-3D, common tolerances for all linear parameters are assigned using the same table of standards. You can assign the desired individual tolerances for blunt edge parameters.

2.10.2.1.1. Deviations file

Maximum deviations of dimensions and parameter values for general tolerances are extracted from the **deviations file**. The file name and location is determined by the GENERALTOLERANCE variable of the environment KOMPAS-3D (see Section 9.5.4 on p. 1886). By default, the deviations file is named as *Gen_tol.ttl* and located in the \Sys subfolder of the KOMPAS-3D main folder. Use *Kompas.ini* (see Section 9.5.3 on p. 1883) if the name and/or position of the deviations file should be different from the default values.

If the deviations file is absent in the path indicated by the GENERALTOLERANCE variable or *Kompas.ini* general tolerances are not assigned to dimensions of sketches and parameter values of operations.

2.10.2.2. Tolerance assignment

To assign or modify tolerance for a sketch dimension or an operation parameter value, the **Assign tolerance** dialog is used (Fig. 2.10.2).

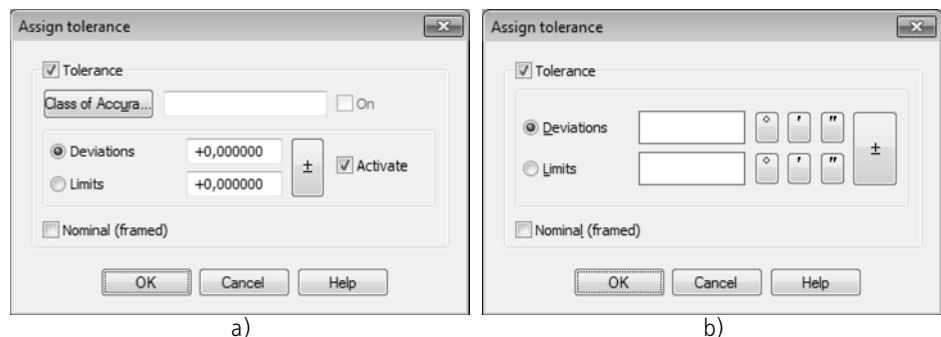

Fig. 2.10.2. Assign tolerance dialog:
a) for a linear value, b) for an angular value

The controls of this dialog are described in Table 3.3.5 on p. 982.

For new dimensions and operation parameters:

- ▼ the state of the **Tolerance** option (enabled/disabled) and the default tolerance value are determined by setting up default tolerances (see Section 9.2.7.2.10 on p. 1838),
- ▼ the state of the following controls: **Deviations, Limits, Enable** is determined by setting up tolerance parameters and tolerance ranges (see Section 9.2.6.10.10 on p. 1779).

The dialog can be accessed both in the course of the operation and out of the process. For more details on calling the dialog, see Section 2.10.2.2.1 on p. 670.

The main actions performed in the dialog are:

- ▼ **Individual tolerance assignment**
Fill in the required dialog fields and click **OK**.
- ▼ **Common tolerance assignment**
Clear all the fields of the dialog and click **OK**.
Common tolerance is assigned for a sketch dimension or an operation parameter value if the **Use Common tolerances according to GOST 30893.1 (ISO2768-1)** option is on in the common tolerances configuration dialog (for information on configuring common tolerances see Section 9.2.7.4.9 on p. 1854). If the option is disabled, no general tolerance will be assigned; the dimension or the parameter value will have an individual tolerance or no tolerance.
- ▼ **Disabling the ability to assign tolerance** (common or individual)
Turn off the **Tolerance** option and click **OK**.

If deviation limiting variables have been created for a sketch dimension or operation parameter (see Section 7.1.5.2 on p. 1592), and the **Expression** field of the Variables window is filled for at least one of them, the following controls will not be available in the dialog: the **Class of Accuracy** button, the field for class of accuracy setting, the option controlling displaying of the class of accuracy, as well as the fields of limit deviations/values of the dimension.

The **Assign tolerance** dialog can be used to modify **the display** of a dimension text for the operation's dimension, for example, to enable showing maximum dimension values instead of deviations. Changes so made are saved before the operation is completed. When the operation is edited again, its dimensions appear based on the setup of tolerance and tolerance range parameters (see Section 9.2.6.10.10 on p. 1779).

2.10.2.2.1. Displaying the Assign tolerance dialog

The **Assign tolerance** dialog (see Fig. 2.10.2 on p. 669) dialog may be accessed both in the course of an operation and out of the process.

In the course of an operation, the dialog appears on the screen after clicking the **Assign tolerance** button. The button is located on the Property bar next to the operation's numeric parameter field.

The **Assign Tolerance** button is available in the Property bar if the **Tolerance Control Buttons** option is enabled in the Property bar display parameters setup dialog (see Section 9.1.3.6 on p. 1683).

When out of the operation process, the **Assign tolerance** dialog may be accessed from Variables window (see Section 7.1.4.2 on p. 1587).

The Assign tolerance dialog may be also called when editing a sketch or operation dimension by clicking the **Assign Tolerance** button in the dimension value setting dialog. For more information about dimension value setting, see Section 2.9.2.2.1 on p. 634.

2.10.3. Model dimensions recalculation mode

Model dimensions recalculation mode is a special KOMPAS-3D mode for working with three-dimensional models. This mode is used to recalculate model object and component dimensions taking into account the assigned tolerances (both common and individual, see Section 2.10.2 on p. 667). Model dimensions calculation is done in accordance with the current recalculation.

KOMPAS-3D supports three system recalculations of dimensions: **to middle part of the tolerance field, by upper limit** and **by lower limit**. It is also possible to create **user** dimension recalculations. For more information on recalculations of dimensions, see Section 2.10.3.1 on p. 672.

When you activate the recalculation mode, the following happens:

- ▼ the values of variables corresponding to the model dimensions to which tolerances are assigned are changed in accordance with the parameters of the selected recalculation;
- ▼ the recalculated values of variables are displayed in the **Recalculated Value** column of the Variables window;
- ▼ the following text is added to the header of the document window: “(Recalculation — <the name of the selected recalculation>)”;
- ▼ the model is rebuilt based on new variable values.

For example, system recalculation of dimensions is used for the model transformation by upper limit. When you enable the mode, all the dimensions involved in the recalculation take the highest limit values. The model is rebuilt using the new dimensions.

As model recalculation using tolerances actually means rebuilding the model with the new variable values, you should remember that:

- ▼ dimensions that do not affect the model (information dimensions or the dimensions that do not have a variable) do not change even if they have a tolerance;
 - ▼ to be rebuilt correctly, the model must be correctly parameterized (e.g., a sketch must be completely defined, etc.).
-

In the recalculation mode, the common tolerance settings configured and saved in component files are applied to model components. If the use of common tolerance is disabled for a component, the common tolerances are not applied to the dimensions of such a component when the recalculation mode is active.

Recalculation control is performed using the **Document manager** (see Section 2.10.3.2 on p. 673).

To enable the model dimensions recalculation mode, click the **Recalculate dimensions based on tolerances** on the **Modes** bar or call the command of the same name from the **Service – Recalculate dimensions** menu.

The **Recalculate dimensions based on tolerances** button is not available when editing a component in-place.

The **Recalculate dimensions based on tolerances** button menu contains: the list of all recalculations of the model dimensions and the **Recalculation Control...** and **Create Copy** commands. The commands for creation of new objects and for editing existing objects are unavailable if the recalculation mode is enabled. For more information on working in the mode see Section 2.10.3.3 on p. 679.

Using the **Save As...** command, the recalculated model can be saved in a different format.

If the model which is in mode recalculation was closed with saving, then upon opening the model its status will be the same as at the closing: recalculation enabled, and the dimensions of the model correspond to the current recalculation.

After disabling the mode, the model will return to the state which it had at the moment of entering the mode.

2.10.3.1. System and user dimension recalculations

Dimension recalculation is a collection of the following parameters:

- ▼ a set of variables corresponding to dimensions of graphic documents or operations (for more information on dimensions, see Section 2.9.2.2 on p. 632);
- ▼ a method to recalculate the value of each variable in the set (see Table 2.10.1).

System recalculations of model dimensions:

- ▼ to middle part of the tolerance field (the default option),
- ▼ by upper limit,
- ▼ by lower limit.

The set of variables for system recalculation is generated automatically. It includes all the variables of the model (including component variables) that are related to dimensions of sketches and operations. The values of the variables from this set are recalculated using one method.

For example, recalculation to the middle of the tolerance field is used to rebuild the model. When you enable the recalculation mode, the variables affected by the recalculation take the values corresponding to the middle of the tolerance field. The model is rebuilt using the new variable values.

Users can create their own dimension recalculations, called **user recalculations**. The set of variables for user recalculation is created manually. For each variable from the set, a method to recalculate its values is assigned:

- ▼ to the middle of the tolerance field

- ▼ by upper limit,
- ▼ by lower limit,
- ▼ using a factor.

For information on creating, editing, or deleting a user recalculation, see Section 2.10.3.2.1 on p. 676.

Methods for model dimensions recalculation and the corresponding recalculation formulas are given in Table 2.10.1. The letters in formulas have the following meanings:

A – the recalculated value of a dimension (of a sketch or operation),

N – a nominal value of a dimension,

ES – top deviation,

EI – bottom deviation.

Tab. 2.10.1. Model dimension recalculation methods

Dimension recalculation method	The formula for recalculation of dimension corresponding to the recalculation method
to the middle of the tolerance field*	$A=N+(ES+EI) \cdot 0.5$
by upper limit	$A=N+ES$
by lower limit	$A=N+EI$
using a factor**	$A=N+EI+(ES-EI) \cdot K$, where $0 < K < 1$

* It is used by default in the user recalculation.

** It is only used for variables on custom recalculations. It is unavailable for components.

If the sketch or operation dimension is an informational one, the dimension variable value is not recalculated (and remains unchanged).

2.10.3.2. Recalculation a control

Model dimensions recalculation is controlled in the **Document manager**. You can use it to perform the following actions:

- ▼ creation, editing, or deletion of user recalculations;
- ▼ selection of the recalculation to be used for calculation of model dimensions (i.e. making a certain recalculation as current).

Creation, editing, and deletion of custom recalculations are described in Section 2.10.3.2.1 on p. 676, the methods for working with recalculations — in Section 2.10.3.2.2 on p. 677.

Go to **Recalculation control...** to start dimension recalculation control. The command is in the menu of the **Recalculate dimensions based on tolerances** button in the **Modes bar** (see Fig. 2.10.5 on p. 680) and in the **Service — Recalculate dimensions** menu. The command is available outside the recalculation mode.

Upon calling the command, the **Document manager** dialog will appear (Fig. 2.10.3). The **Recalculate dimensions** element is selected and the **list of recalculations** is expanded in the left part of the dialog, in the Document Tree. The list of recalculations contains the names of all the model dimension recalculations, both system and user ones (if any). Letter 's' in parenthesis precedes each system recalculation. The current recalculation will be marked with a red check mark.

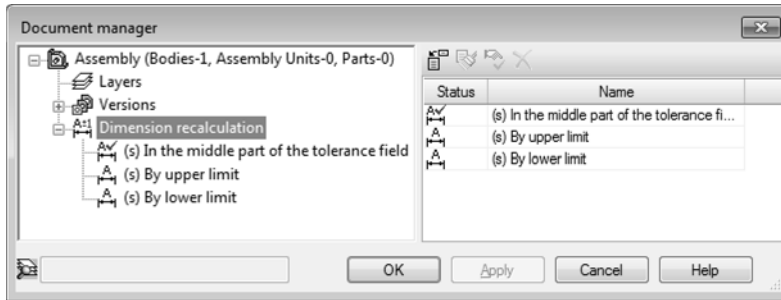

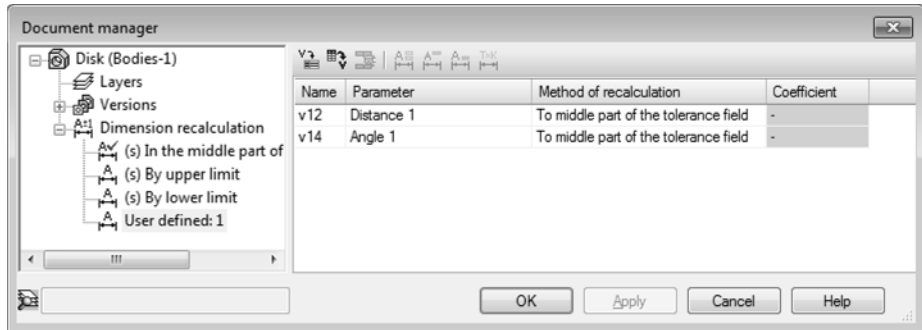

Fig. 2.10.3. Managing the recalculation mode in the Document manager

The right part of the dialog is intended for work with recalculations. Its contents depend on the action currently performed — recalculation control or custom recalculation setup.

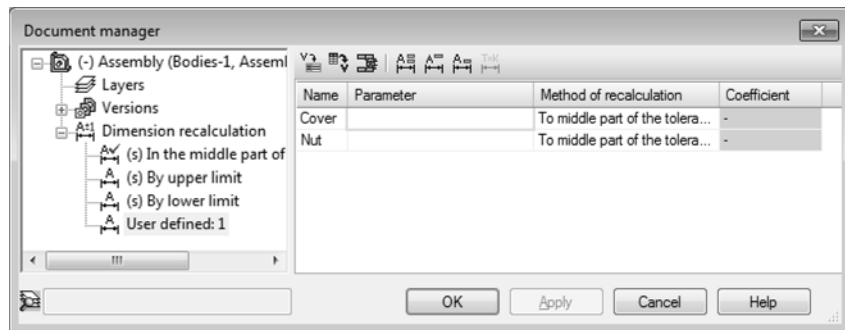

- ▼ Select the **Recalculate dimensions** in the Document Tree for recalculation control. The following appears in the right part of the dialog (Fig. 2.10.3):
 - ▼ a bar with buttons for recalculation control commands,
 - ▼ the list of recalculations as a two-column table: **Status** and **Name**.
- ▼ To set up a custom recalculation, select its name in the Document Tree. The following appears in the right part of the dialog (Fig. 2.10.4):
 - ▼ a bar with buttons for setting recalculation parameters,
 - ▼ the list of recalculated variables as a four-column table:
 - ▼ the **Name** column contains names of variables and/or components,
 - ▼ the **Parameter** column displays the parameter names of the operations whose dimensions need to be recalculated (empty for components),
 - ▼ the **Recalculation method** column is intended for selection of the recalculation method for the value of the variable; each column cell has a drop-down list of recalculation methods: to the middle of the tolerance field, by upper limit, by lower limit, with a coefficient (see Table 2.10.1 on p. 673); if created in the component file, there are custom recalculations in the list for the component; no recalculation with a coefficient is used for components.
 - ▼ The **Coefficient** column serves for setting the coefficient; the coefficient's value can vary from 0 to 1 ($0 < K < 1$).

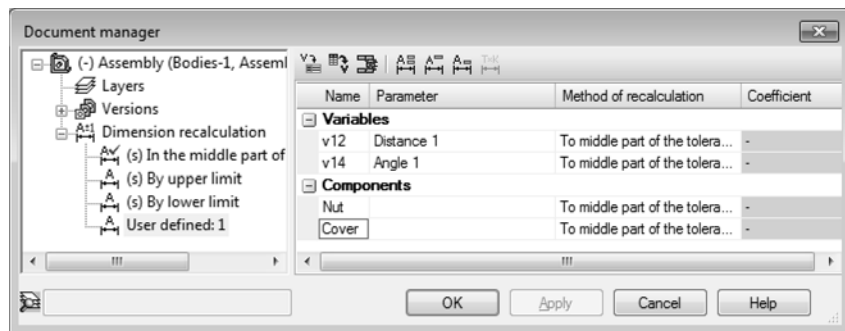

Parameters of a system recalculation are not displayed in the **Document manager** dialog.

a)

b)

c)

Fig. 2.10.4. Display of parameters of a custom recalculation:
 a) the set includes only sketches and operations dimension variables;
 b) the set includes only components;
 c) the set includes both sketches and operations dimension variables and components

The variables, components and recalculation methods in components included in the custom recalculation may be deleted during further editing of the model or components. In this case, the cells related to listed objects are highlighted in red in the **Name** column and cleared in the **Parameter** column.

2.10.3.2.1. Creating, editing, and deleting user recalculations

To create, edit, or delete a custom recalculation, open the **Recalculation control...** menu using the **Recalculate dimensions based on tolerances** button on the **Modes** bar. The **Document manager** dialog will be displayed (Fig. 2.10.3 on p. 674).

In the dialog that appears, perform the following steps.

To close the **Document manager** dialog, click **OK**.

Confirmation of each modification in the **Document manager** dialog is not required, since modifications are saved in the model immediately after their execution.

Creating a user recalculation

In order to create a user recalculation of model dimensions, perform the following actions.

1. Select the **Recalculate dimensions** element in the left part of the **Document manager** dialog.
2. Click the **Create** button on the toolbar of the **Document manager** dialog.
3. Indicate the created recalculation in the list of recalculations in the left part of the dialog.
4. Generate a set of variables and/or components of the new recalculation.

▼ Use one of the following methods to add variables.

▼ In the Design Tree or the model window, specify the derivative dimensions corresponding to the required dimensions of sketches and operations (the derivative dimensions must be created in advance, see Section 2.9.2.8 on p. 648).

▼ Add the desired set of model variables using **Read variables** or **Insert variable** buttons on the toolbar of the **Document manager** dialog (for details, see Section 2.10.3.2.2 on p. 677).

▼ To add a component, select it in the Design Tree or in the model window. Please, note that all first-level components are involved in recalculation of dimensions, i.e. objects or variables of a component cannot be selectively indicated.

Rows corresponding to the variables and/or components of the set appear in the list of variables of the new recalculation.

5. Specify a method to recalculate each variable and component. To do this, select the required method from a drop-down list in each cell of the **Method** column. **to the middle of the tolerance field, by upper limit, by lower limit, using a coefficient** (for more information on the methods of dimensions recalculation see Table 2.10.1 on p. 673). When a method **with a coefficient** is used, enter the value of the coefficient from 0 to 1 in the respective cell of the **Coefficient** column.

Please, note special features of setting up the component recalculation:

- ▼ the method of recalculation **with a coefficient** is not available,
- ▼ when **to the middle of the tolerance field, by upper limit** or **by lower limit** is selected as the method, all component variables are recalculated with this method,
- ▼ custom recalculations created in the component file are available for selection.

To move between cells, use arrow keys.

You can create a new user recalculation using parameters of an already existing system or user recalculation as a template. To create a custom recalculation using an existing one as a template, use the **By sample** button on the toolbar of the **Document manager** dialog (for details, see Section 2.10.3.2.2 on p. 677).

Editing a user recalculation

Editing a user recalculation is very similar to its creation. To start editing, open the **Document manager** dialog by performing the actions described above.

Deleting a user recalculation

A user recalculation may be deleted if it is no longer required. For this, do the following.

1. Open the **Document manager** dialog by performing the actions described above.
2. Select the required calculation 's name in the list.
3. Click **Delete recalculation** on the dialog's toolbar or call the command from the recalculation's context menu.

The selected recalculation is removed from the list.

2.10.3.2.2. Techniques of work with recalculation modes in the Document manager

It is assumed when describing techniques of work with recalculation modes that the **Document manager** dialog is open and **Recalculate dimensions** is selected in the Document Tree in its left part.

Creating a user recalculation

Click **Create** on the toolbar of the **Document manager** dialog or call the command from any recalculation's context menu. A new recalculation is added to the list.

Creating a user recalculation using parameters of an existing recalculation

Select the sample recalculation in the list and click the **By sample** button or call the command from the context menu. The new recalculation with parameters of the sample recalculation is added to the list.

If a system recalculation is selected as a template, all the variables of the current model that correspond to sketches and operations dimensions will be included in the new recalculation. The recalculation method of each variable value in this recalculation will match the one in the selected system recalculation.

If required, you can change the parameters of a recalculation created using a template.

Selecting the current recalculation

Select the necessary recalculation in the list and click the **Make current** button or call the command from the context menu. A check mark appears in the list of recalculations on the icon. This means that the selected recalculation is now active (current), i.e. this recalculation will be used as the basis for recalculation of model dimensions.

There is another method available to make a recalculation current. Double click the necessary line in the list of recalculations to activate it.

Renaming a custom recalculation

Click the necessary cell in the **Name** column to activate it and enter the new name of recalculation. To move between cells, use arrow keys.

Recalculation can also be renamed in the Document Tree. To do this, click the mouse once to select the recalculation name and click again to make it available for editing, then enter the new name.

System recalculations cannot be renamed.

Deleting a user recalculation

Select the necessary custom recalculation in the list and click **Delete** or call the command from the context menu.

Please note that system recalculations cannot be deleted.

Adding a set of variables corresponding to dimensions of graphic documents or operations into a user recalculation

Select the required custom recalculation in the Document Tree and click **Read variables**. All the variables of model operations dimensions and parameters involved in recalculation of its dimensions will be added to the list of variables to the right.

Please note that the variables of the model operations dimensions and parameters that have the status of informational will not be added to the list of variables (see Section 7.1.1.2.1 on p. 1570 for more information about informational variables).

Adding a particular model variable in a user recalculation

Select the required custom recalculation in the Document Tree and click **Insert variable**. The **Variables** dialog allowing to select the required variable from the variables list of the current document appears on the screen. Specify the required variable and click the **OK** button. The chosen variable will be added to the selected recalculation.

Adding components to a custom recalculation

Select the necessary custom recalculation in the Document Tree. Indicate the component to be added by clicking on it in the Design Tree or in the model window. The line with the component's name will be added to the selected recalculation.

Deleting variables and components from a custom recalculation

Select the necessary custom recalculation in the Document Tree. Then select the required lines or any cells of these lines in the right part of the dialog and click **Delete lines**.

Line deletion means that the variable or component corresponding to this line is removed from the custom recalculation. The variable or component remains unmodified in the model.

Selecting the recalculation method of the variable value

Select the necessary custom recalculation in the Document Tree. Then activate the cell of the variable a recalculation method needs to be assigned to in the **Recalculation method** column in the right part of the dialog. Select the desired method of recalculation from the drop-down list of this cell (for information on dimensions recalculation see Table 2.10.1 on p. 673) or click a button corresponding to the desired recalculation method on the toolbar:

▼ To the middle of the tolerance field,

▼ By upper limit,

▼ By lower limit,

▼ Using a factor.

2.10.3.3. Enabling dimensions recalculation mode and working in it

To enable the model dimensions recalculation mode, click **Recalculate dimensions based on tolerances** on the **Modes** bar or call the command of the same name from the **Service — Recalculate dimensions** menu.

The **Recalculate dimensions based on tolerances** button is not available when editing a component in-place.

Menu of the **Recalculate dimensions based on tolerances** command contains the list of all recalculations of the model's dimensions and commands **Recalculation Control...** and **Create Copy**.

This menu is called by clicking on the triangle located near the button.

Fig. 2.10.5. The **Recalculate dimensions based on tolerances** button menu contains:

All commands of the **Recalculate dimensions based on tolerances** command menu, except for user recalculations, can also be called from the **Service — Recalculation of Dimensions** menu.

The commands for creation of new objects and for editing existing objects are unavailable if the recalculation mode is enabled. Only the following actions can be performed:

- ▼ model viewing and printing (on printing, see Section 8.1 on p. 1631);
- ▼ measuring geometrical (without creating modification objects) and mass center characteristics of the model (see Section 2.15.2 on p. 812);
- ▼ report creation (see Section 5.2 on p. 1403).

In addition, in the recalculation mode you can:

- ▼ change the current recalculation (see Section 2.10.3.3.1 on p. 680);
- ▼ create a copy of the recalculated model (see Section 2.10.3.3.2 on p. 681).

To exit the dimensions recalculation mode, release **Recalculate dimensions based on tolerances** or click the recalculation mode icon in the document window with the mouse.

2.10.3.3.1. Selecting the current dimensions recalculation

Current recalculation — the recalculation based on which model dimensions are recalculated in the recalculation mode.

The current recalculation is ticked in the **Recalculate dimensions based on tolerances** button menu in the **Modes** bar (Fig. 2.10.5).

To select a current dimensions recalculation, complete the following steps.

1. Open the list of recalculations. To do this, click the triangle located to the right of the **Recalculate dimensions based on tolerances** button
2. Select the desired recalculation from the list.

A checkmark will appear next to the selected recalculation.

Selection of the current recalculation from the **Recalculate dimensions based on tolerances** button menu is available both inside and outside the dimensions recalculation mode. Outside the recalculation mode, the current recalculation can also be selected in the **Document manager** (see Section 2.10.3.2.2 on p. 677).

2.10.3.3.2. Creating a copy of a recalculated model

Working in the model dimensions recalculation mode, you can save the variant of the current model whose nominal dimensions are dimensions recalculated within the current recalculation. By changing recalculation, you can create several model variants with different dimensions — from smallest to largest limits.

Use **Create copy** to save a model with recalculated dimension values. It is in the menu of the **Recalculate dimensions based on tolerances** button in the **Modes** bar (see Fig. 2.10.5) and in the **Service — Recalculate dimensions** menu.

The **Create a copy** command is available in the dimensions recalculation mode only.

After calling the **Create copy** command, the File Save dialog will appear. Use it to specify file name and folder for saving and click the **Save** button.

When you create a copy, the following happens:

- ▼ objects created directly in the model acquire the recalculated dimension values,
- ▼ for model components, the recalculation method that are inserted with changes (see Section 2.16.2.1 on p. 861); component files are not modified on the disk.

A copy of a recalculated model is not different from a model constructed from scratch, i.e. you can work in a usual manner with it in the future.

Unlike **Create copy**, **File — Save as** saves a model without changing nominal dimensions.

2.11. Components

2.11.1. General details about components

Component is part of a model represented by another model. Model components can include parts, assemblies, base and local parts; assemblies can also be standard products and library models.

Component model can be stored in a separate file or current part file.

Separate files are used to store the following components:

- ▼ parts,
- ▼ assemblies,
- ▼ base parts with a history,
- ▼ standard products,
- ▼ library models.

In this case, the current model does not actually contain the components themselves, but rather links to the respective files. This is why it's necessary to transfer component files along with this kind of model in order to move the model to another workplace.

Separate files are used to store the following components:

- ▼ local parts,
- ▼ base parts without production history.

These components do not have special files allocated for them. They are stored in the models that contain them. Using local parts and base ones without production history allows creating a assembly model file, with all the model parts stored in the same file.

To add components to a model the following methods are used:

- ▼ insert component from file (see Section 2.11.2.1 on p. 684),
- ▼ build component in the context of current model (see Section 2.11.2.2 on p. 687),
- ▼ convert current model objects into part/local part (see Section 2.11.2.3 on p. 689).

Components can be linked by matings between themselves or with other model objects. Two types of a matings are available: positioning and mechanical. Positioning matings restrict positions of objects in relation to each other (for example, set the alignment of the pivot and the hole), while mechanical matings set a law of motion for objects in relation to each other (for example, translational movement of the nut during the rotation of the bolt). Creating matings is described in Section 2.11.4 on p. 703.

One and the same model can be inserted as a component into several other models, and, likewise, a model can contain several inserts of a component.

Operations that imitate processing an assembled product can be performed within a component-containing model. Usually these are operations of removing material; for example, making a hole running through several components. Please notice that the result of such an operation is not saved to component files, but is stored in the containing model instead. If you open the component files, you will see that they have no record of the hole. Thanks to this, the same

component can be inserted into different models while performing various operations in them, as well. This will not result in the component file changing on the disk.

If there is a need for changes made to a component to be reflected in all the models that contain it, its file needs to be opened and edited appropriately. A component can be edited either 'in place', i.e. in the screen of the model that contains it (see Section 2.11.6.2 on p. 723), or in a separate screen (see Section 2.11.6.1 on p. 722). For components stored in the current model only on-the-spot editing is available.

If necessary, you can change the position of a component in a model and its insertion settings (see Section 2.11.6.3 on p. 724).

If the components are parts, Boolean operations of subtraction and grouping can be conducted with them (see Section 2.11.5 on p. 720).

By default, the components inserted into a model keep their own mass-center characteristics and properties (designation, title, etc.), i.e. written to their respective files. If necessary, you can set MP (see Section 2.14.6.3 on p. 805) and properties (see Section 5.1.4.1.2 on p. 1387) for a component that differ from its own. This data is not written to the component file, it is stored in the containing model.

2.11.2. Adding a component to a model

Commands to add components are placed in menu **Operations**, and the buttons to call them — on the panel **Assembly Editing**.

While working with a part (*.m3d) the adding commands are available on the **Assembly editing** panel only. To display it select **View — Toolbars — Assembly editing**.

If the model should include several identical components, you can insert them all by copying and pasting the first inserted component the required number of times (see Section 2.14.4.4 on p. 800). If you need to arrange copies of the component in a specific manner (for example, along some curved line, or as a grid with specified parameters), we recommend to use the commands for arrays creation (see Section 2.7 on p. 509).

2.11.2.1. Adding a component from file

Another model (part or assembly) stored in a file on disk can be inserted into a model as a component.

Model insertion from a file can be used for the following components:

- ▼ part,
- ▼ subassembly,
- ▼ local part,
- ▼ base part.

The position of the component in the model is specified during the insertion. The following methods are used for this:

- ▼ **By coordinates**,

▼ By matings.

If a component's position is set using **By coordinates**, and the component is the first one in the current model it gets fixed in position automatically. For details about fixation, see Section 2.11.3.4 on p. 702.

If an inserted component is a model's variant, you can replace it with another variant of the model. For this purpose, call the **Current variant** command from the component's context menu in the Design Tree and specify the required variant in the appearing list of the model's variants. A tick will appear next to the designation of the chosen variant in the list. This will result in inserting the version in the model. After replacing the component rebuild the model (for details about model rebuilding, see Section 2.14.3.7 on p. 795).

Later on, you can change the position of the inserted component within the model, or edit its parameters (see Section 2.11.6.3 on p. 724).

2.11.2.1.1. Adding a part/subassembly from file

To add a part or subassembly stored in a file as a component, perform the following actions.

1. Call the **Operations — Add from file — Component...** command or click the **Add from file** button on the **Assembly Editing** bar.

2. In the open file dialog box, select the file that contains the required model (see Section 2.11.2.5.1 on p. 692).

A ghost of the selected model will appear in the current model screen, and the Properties panel will get two additional tabs: **Position** and **Properties**.

3. Use the **Position** tab to set the component position parameters in the model (see Section 2.11.2.5.2 on p. 692).

4. On the **Properties** tab, set the color and optical properties of the component (control elements used for this are described in Section 2.14.2 on p. 784), turn on/off specification object creation.

On this tab, you can also select new values of model external variables, provided the inserted component contains a variable table. For this, you need to click the **Table of variables** button and select the required row in the table that appears on the screen.

5. To complete component insertion click the **Create object** button on the Advanced Control Panel.

An icon that corresponds to the component type (part or assembly) will appear on the Model Design Tree, while the name of the component retrieved from its source file appears next to the icon.

2.11.2.1.2. Adding local part from file

A part or assembly, stored in a file, can be inserted as a local part.

The model chosen for insertion may contain local parts already. In this case, please take note of the following.

- ▼ If the chosen model is an assembly, then either the whole of the assembly or any one of its local parts can be inserted.

- ▼ If the chosen model is a part, only the whole of the said part can be inserted. No local part it may contain will be available for selection.

To add a local part to a model, perform the following actions.

1. Call the command **Operations — Add from file — Local part...** or click the **Add local part from file** button on the **Assembly editing** panel.

2. In the open file dialog box, select the file that contains the required model (see Section 2.11.2.5.1 on p. 692).

If the chosen model is an assembly that in turn contains local parts a **Select local part** dialog box will appear on the screen.

To insert one of the local parts in an assembly as a local part, specify it in the dialog box and click **OK**.

To insert the whole of the assembly as a local part, click **Cancel**.

After selecting the source model a ghost of the local part will appear in the current model screen, while the Properties panel will get additional two tabs—**Position** and **Properties**.

3. On the **Position** tab set the position parameters for the local part within the model (see Section 2.11.2.5.2 on p. 692).
4. On the **Properties** tab, set the color and optical properties of the component (control elements used for this are described in Section 2.14.2 on p. 784), turn on/off specification object creation.

On this tab, you can also select new values of local part external variables, provided the source model contains a table of variables. For this, you need to click the **Table of variables** button and select the required row in the table that appears on the screen.

5. To complete local part insertion click **Create object** button on the Advanced Control Panel.

Local part will now be inserted in the current model.

An icon that corresponds to the component type (part or assembly) will appear on the Model Design Tree, while the name of the component retrieved from its source file appears next to the icon.

The local part is stored in the file of the model it has been inserted into.

2.11.2.1.3. Adding Base part

A convenient technique in modeling products that differ only in few design details is to use a previously created model (part or assembly) as a base part.

The model that you plan to use must be written to the disk in a file named however you like.

To insert a finished model as a base part, perform the following actions.

1. Call the command **Operations — Base part...** or click the **Base part** button on the **Model editing** panel.

2. In the open file dialog box, select the file that contains the required model (see Section 2.11.2.5.1 on p. 692).

A ghost of the selected model will appear in the current model screen, and the Properties panel will get two additional tabs: **Position** and **Properties**.

3. On the **Location** tab, proceed as follows.

- ▼ Set the base part's position parameters in the model (see Section 2.11.2.5.2 on p. 692).
- ▼ Select base part insertion method. To do this, activate the applicable switch in the **Insertion method** group.

If the **Insertion by external link** switch is enabled, the link between the base part and the source file is kept. The base part is not copied into the model, but exists in it as a link to its file. If the source file is subsequently edited, the changes will be automatically sent to the model that uses this base part (model rebuilding is required for transmitting changes, see Section 2.14.3.7 on p. 795).

If the **Insertion without history** switch is enabled, the link between the base part and the source file is not kept. Editing the source file does not affect the base part inserted using this method.

- ▼ If the base part is required to be a mirror image of a model from a file, turn the **Mirrored insertion** option on. With this option on the base parts will be positioned symmetrically to their initial position relative to the selected plane. The plane is selected from the **Symmetry plane** list, which becomes available after the option is turned on.

4. On the **Properties** tab, set the base part's color and optical properties. Control elements used for this are described in Section 2.14.2 on p. 784.

On this tab, you can also select new values of the base part's external variables, provided the source model contains a variable table. For this, you need to click the **Table of Variables** button and select the required row in the table that appears on the screen.

5. To complete base part insertion click **Create object**.

The base part will now be inserted in the current model. An icon that corresponds to the base part insertion method used will appear on the Model Design Tree:

- ▼ base part inserted using an external link,

- ▼ base part without history.

The name of the base part retrieved from the source file will appear next to the icon.

If the position of the base part is set using the **By coordinates** method, it is fixed automatically.

2.11.2.2. Creating component 'in place'

While forming an assembly model in KOMPAS-3D, besides adding ready-made components from the disk, you can also create them without leaving the current file, i.e. construct parts and subassemblies in the context of the current model. All the remaining components will be visible in the window, too. They are unavailable for editing, but their elements (facets, edges, summits, outlines, etc.) can be used in the operations of creating new components.

The component (part, subassembly, local part) created in the context of the current model is linked with the model by a *Coincidence* matings (see Section 2.11.4.2.2 on p. 707). The matings is referenced to the component's absolute coordinate system and the model's relative coordinate system. The mating's icon appears in the group of matings of the Design Tree. If necessary, you can edit or delete the automatically-created mating.

Later on, you can change the position of the created component within the model, or edit its parameters (see Section 2.11.6.3 on p. 724).

When creating a component within a model you need to name a file for the component and select a folder to save it in. If a file with the same name already exists in the selected folder, it is not possible to overwrite it. You need to change the name of the file or select a different folder to save it in. In addition, if a model from this file is a component of one of the open models, attempting to overwrite results in interrupted creation of the component.

2.11.2.2.1. Creating a part 'in place'

To start building a part directly within the current model, call the command **Operations — Create — Part** or click the **Create part** button on the **Assembly editing** panel.

In the open file dialog box that pops up specify the folder and the name of the file to save the new part to and click **Save**.

An icon designating the new will appear on the Model Design Tree. The system will automatically switch to context editing mode for the part. Operation in this mode is described in Section 2.11.6.2.1 on p. 724.

As you finish building the part, release the **Edit in place** button on the **Current status** panel, and use the context menu to call the command **Edit in place**, or click the context editing mode icon in the model screen. The system will return to main model operation mode.

If you plan to build the first element of the part being created based on an outline, and a 2D object to place it on is already available in the model, specify the object before calling the part creation command. In this event, after saving the file of the part and turning on the context editing mode, the system automatically switches to editing mode for the outline located in the specified plane. Make required constructions and exit the sketch mode.

2.11.2.2.2. Creating subassembly 'in place'

To begin building a subassembly directly in the current model, call the command **Operations — Create — Assembly** or click the **Create assembly** button on the **Assembly editing** panel.

In the save file dialog box specify the folder and the name of the file to save the new assembly to, and click **Save**.

An icon designating the new subassembly will appear on the Model Design Tree. The system will automatically switch to the building mode for the subassembly in the context of the model that contains it. Operation in this mode is described in Section 2.11.6.2.1 on p. 724.

As you finish creating a subassembly, release the **Edit in place** button on the **Current status** panel, or use the context menu to call the command **Edit in place**, or click the context editing mode icon in the model screen. The system will return to main model operation mode.

2.11.2.2.3. Creating local part 'in place'

To start building a part directly within the current model, call the command **Operations — Create — Local part** or click the **Create local part** button on the **Edit assembly** panel.

Creating a local part 'in place' is similar to creating a part 'in place' (see Section 2.11.2.2.1 on p. 688) with only one difference: it is not required to enter the name of the file of the part since a local part is stored in the same model where it is created.

2.11.2.3. Transforming objects

To create model components you can use transforming objects available in a given model into a part. While working on an assembly objects can be transformed into a local part.

Transformation can only be performed on objects built directly in the current model. These include:

- ▼ bodies,
- ▼ surfaces,
- ▼ 3D curves and points,
- ▼ local coordinate systems,
- ▼ auxiliary planes,
- ▼ auxiliary axes.

If necessary, you can transform objects built within a component into a part. This requires entering the editing mode for the component.

Transforming objects into a part or local part cannot be undone. Nor is it possible to undo operations performed within the model before the transformation.

The following transformations are available for components: transforming a part into a local part and, vice versa, a local part into a regular part.

- ▼ To transform a usual part into a local one, select it on the design tree and call the command **Embed into document**. While working with an assembly the command is called from the **Editor** menu or a context menu; while working with a part, it can only be called from the context menu. After calling the command, the selected part is removed from the model and re-inserted into it as a local one.
- ▼ To transform a local part into usual part, select it on the Design Tree and call the **Save as...** command from a context menu. The Save file wizard dialog will appear. Set the name of the file and specify the folder to save it in. Once it is saved, the local part is removed from the model and re-inserted into it as usual one.

2.11.2.3.1. Transforming objects into a part

Transforming objects into a part is to save the objects built within a model (part or assembly) to the file of a new part (*.m3d). If a transformation is conducted within an assembly, the resulting part is inserted into it as a component.

While working with a part, objects selected for transformation are transmitted to the new part and saved in the original one unchanged.

While working with an assembly, objects selected for transformation can be deleted from the assembly in the process of transformation.

Transforming objects into a part is performed using the command **Editor — Create part**.

You can select objects you need both before and after calling the command. The objects to be transformed are specified on the Design Tree or model screen (to specify a body or surface you can select its any facet, rib or summit).

If you have selected a body (or surface) on the Design Tree, you can call the **Create part** command from the context menu.

Upon calling the command, the transformation controls appear on the Properties bar. To set transformation parameters use the following steps.

1. Set the designation of the part being created. To do so, click the **Designation** field and follow the instructions in the dialog that opens. Working with the dialog is described in Section 2.13.2.1.1 on p. 756.
2. In the **Name** field, enter the name of the part being created.
3. For a set of objects being transformed using the **List of objects** panel. Objects selected prior to calling the command are already included in the list. To add an object to the list specify it on the Design Tree or model screen (to specify a body or surface in the model screen, you can select any of its faces, edges, or vertices). Specifying the object a second time will result in deleting it from the list. You can also delete an object by selecting it on the list and clicking the **Delete from list** button.

You can add only those objects to the list whose types are listed in see Section 2.11.2.3 on p. 689.

4. Using the **Method** group of switches select a method to save the objects to the file of the part. **Saving with history** option button is active in this group by default. This means that the new part will receive both the objects themselves and those of the original objects whose transmission is possible. In the event it is impossible to transfer the original objects the following data is transferred:
 - ▼ if transformation takes place in a part, copies of the geometry of original objects will be created in the new part (for details about copying geometric objects, see Section 2.8.7 on p. 624),
 - ▼ if transformation takes place in an assembly, links to the assembly file will be generated in the new part, similar to those that are formed in the component file during its editing 'in place' provided objects from other assembly components are used.

A Boolean operation on a body is transmitted to the part correctly only when the other body taking part in the operation belongs to the current model itself, not to one of its components.

A part obtained from a body produced by a *Add thickness* returns an 'Cannot perform this operation' error. If the operation modifies the body instead of producing it, the transformation will be successful.

When saving with history, apart from initial objects, all expressions used for calculating parameters of elements of the objects being transformed will be passed to the part, as well as all main section's variables.

The position of the objects is saved during the transmission, i.e. the transmitted objects will be located in the part's coordinate system exactly the same way as in that of the original model.

If you need to pass only objects themselves to the part, without initial objects and variables, turn on the **Save without history** switch in the **Method** group. The **Mirroring** option will become available, too. Enable this option if it is required that all objects passed to the part be positioned symmetrically to their initial position relative to one of the coordinate planes. The appropriate plane is selected from the **Symmetry plane** list, which becomes available on enabling the option.

5. Additional operations are available when working with assemblies.
 - ▼ Enable the **Composition geometry** option, if you need to add a new part to the assembly not as a component, but as a composition geometry.
 - ▼ Enable the **Delete original** option, if you want the objects to be deleted from the assembly after transformation. Please note that only objects selected for transformation can be deleted. Their initial objects remain intact.

If the object transformed into the part was involved in mating, then, in case of deleting the original, a new part will participate in relevant matings; if the original is saved the matings will not be changed.

6. After setting all transformation parameters, click the **Create object** button on the Advanced Control Panel. Windows-standard File Save dialog will be displayed. Specify both folder and part file name for saving, then click the **Save** button. The selected objects will be saved to the specified file.

2.11.2.3.2. Transforming objects into a local part

Transforming objects into a local part is possible only when working with assemblies.

Objects built in a current assembly are transformed into a local part of the same assembly. The created local part is automatically added to the list of the current assembly's components.

Transforming objects into a local part is performed using the command **Editor — Create local part**.

Transforming objects into a local part is similar to transforming objects into a part (see Section 2.11.2.3.1). The difference is that transforming into a local part does not create a separate part file (*.m3d). Local part is stored in the file of the same assembly in which it is created.

2.11.2.4. Adding standard item

If standard items (bolts, nuts, screws, etc.) are used in a product, you do not need to model them as unique parts. Standard item models can be inserted from **Standard item library**.

If **Standard item library** is installed on your workstation, the **Libraries** menu will have the **Standard items** item. It contains a submenu of commands for access to library functions.

To insert a standard item into a model, call the command **Libraries — Standard items — Insert — Insert element**. In the appearing dialog, double-click the required standardized part, set its parameters, and click **Apply**. Indicate the part's insertion point in the model window or objects for mating and then click the **Create object** button on the Special control bar.

The inserted item shall appear in the model window and its icon — in Design Tree.

More information on the **Standardized parts library** can be found in its help system.

Main methods of working with standardized parts — shift and rotation, matings, setting properties, access management and others — are the same as when working with a unique component (part, subassembly).

2.11.2.5. Position and component insertion parameters

When adding a component to a model from a file, there are several methods to set its position in the model (see Section 2.11.2.5.2 on p. 692). Position control elements are found on the **Location** tab on the Properties panel.

In addition, you can use the **Properties** tab to set the component's properties, select new values of external variables using the source model's variable tables.

2.11.2.5.1. Selecting component file

After calling one of the commands for inserting a component into the model, an insert source file selection dialog box will appear.

Specify the required model file.

If the model contains variants, geometry and properties of the component will correspond to one of these variants. The list of all variants, that exist in the model, is contained in the **Variant** list of the file selection dialog. Specify the required variant in the list.

If additional numbers of variants are created in the chosen model, the dialog will also contain the **Additional Number** list. By default, the list has the activated variant under which none of the additional numbers is selected (empty line of the list). If necessary, choose the line with the required number.

To complete selection of the model, click **Open**.

2.11.2.5.2. Setting component position parameters

The parameters that determine the position of the component are set on the **Location** tab on the Properties panel.

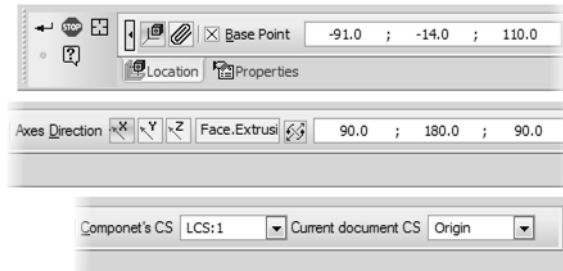

Setting parameters depends on the method of component positioning: **By coordinates** or **By matings**. You can select the method you want using the group of **Location method** switches.

The set of elements and component positioning procedure for each method are given below.

By coordinates location method

Control elements displayed on the **Location** tab while using the **By coordinates** method are shown in Fig. 2.11.1.

Fig. 2.11.1. **By coordinates** method

To set the position of a component using this method, perform the following actions.

1. Set the position of the insertion point for the components, i.e. the same location as the origin of the current coordinate system of the component.

The following ways to set the position are available.

- ▼ Manual in the model screen. The insertion point can be specified at lib or using a snap (for example, to the coordinate origin or to a vertex). To make the snap, position the cursor on the required object and left-click the object's symbol as soon as it appears next to it.

Snap to the zero point of the current coordinate system can be made using the keyboard. For this purpose, press **<Ctrl>+<O>** and then the **<Enter>** key.

- ▼ Inputting coordinates in the **Base point** field.

- ▼ Point creation. To do so, click the **Create Point** on the Advanced Control Panel. This will initiate the process of point creating (see Section 2.5.2.11.1 on p. 347). Select a construction method and specify the required parameters. These parameters will determine the position of the component's insertion point. Please note that in this scenario the point construction process is used solely for determining the position of the insertion point. No new point is created in the process.

The position of the insertion point is fixed using an option next to the **Base point** field. Cross corresponds to the on state of the option (i.e. the insertion point is fixed), while a check mark indicates that it is in the off state.

The option turns on automatically in the following cases:

- ▼ after setting the insertion point manually in the model screen using the above methods,
- ▼ after inputting all three coordinates in the **Base point** field,
- ▼ upon completion of the point creation process.

When needed, you can turn the option on/off manually.

Editing coordinates in the **Base point** field and creating a point using the **Create Point** command are available regardless of whether the option is enabled or not.

You can manually set the insertion point even if the option is off. If the option is on, you can only drag the component beyond the origin of its coordinate system.

2. Set the orientation of the component's coordinate system using guiding objects or Euler angles.

To select the axis to set the respective direction, enable the appropriate switch in the **Axes Direction** group:

- ▼ **Guiding object for X axis,**

- ▼ **Guiding object for Y axis,**

- ▼ **Guiding object for Z axis.**

The guiding object display field and a button for changing the axis direction to the opposite will appear on the Properties panel. The button corresponds to the selected axis:

- ▼ **Flip the X axis,**

- ▼ **Flip the Y axis,**

- ▼ **Flip the Z axis.**

Specify a guiding object in the model screen. The name of the object will appear in the **Axis guiding object** field. The axis will establish an associative link with this object.

If necessary, flip the axis direction using one of the button described above.

Direction can be set for two axes only. The third axis will be automatically directed in such a way so as to form a right-hand system with the first two.

After you select a guide object for the first axis, the component coordinate system will rotate so that this axis has the direction specified by this object.

The guide object direction for the second axis can be non-perpendicular to the first axis. In this case the direction of the second axis is defined as a projection of the direction, defined by the object, on the plane perpendicular to the first axis.

If the object is either parallel to or on the same axis with the first axis, such object can not be used as a guide for the second axis.

To set axis orientation you can use the **Euler angles** field. The field is used to input nutation, precession and rotation angles. In case you select guiding objects, these angles are calculated automatically and their values appear in the field. You can change the value of the angles at any time. As you do so, the current selection of guiding objects will be canceled.

You can control the position of the component in the model using a base element (see Section 2.11.2.5.3 on p. 696).

3. You can control the position of the component in the model using coordinate systems. Initially, the component is placed in a model as follows:
 - ▼ the origin of the component coordinate system coincides with the insertion point,
 - ▼ axes of the component's current coordinate system are co-directional with those of the model's current coordinate system,
 - ▼ coordinates of the insertion point and Euler angles are determined relative to the current coordinate system of the model.

You can change the position of the component in the model by specifying another coordinate system or current model. Use the respective lists for this purpose. Availability of lists depends on the availability of local coordinate systems in the component/current model.

The component's coordinate system is chosen from the **Component CS** list. It is combined with the insertion point and location of the component changes.

In order to choose a coordinate system for the current model, use the **Current document's CS** list. If the CS is chosen while the **Save position** option is disabled, the coordinates of the insertion point remain unchanged but are counted in the chosen coordinate system. As a result, the component's position will be changed in the model. If the **Save position** option is enabled, the choice of the model's CS does not affect the component's position in it. The coordinates of the insertion point and Euler angles change (their values are determined relative to the current coordinate system).

If necessary, you can change the position of the component's coordinate system when placing the component. For this purpose, click the **Change component's CS position** button in the Advanced Control Panel. The LCS creation process will start (see Sections 2.8.3.6 on p. 602 and 2.8.3.7 on p. 606). Specify LCS parameters and click the **Create object** button. The system will return to the component construction process. In the **Component CS** list, the *Modified* line will appear. Please note that in this scenario the LCS creation process is used solely for determining the position of the component's CS. No new LCS is created in the process.

Note the following feature when setting a new position for CS. If the **Create LCS only in absolute CS** option is enabled during the system setup in the **LCS** dialog (see Section 9.1.11.9 on p. 1734), the CS position is defined relative to the component's absolute CS; otherwise, it is defined relative to the current CS.

CS position change and selection of another CS are only used in the current component location process. This data is not saved in the system.

Matings positioning method

Control elements displayed on the **Location** tab when the **By matings** method is selected are shown in Fig. 2.11.2.

Fig. 2.11.2. **By matings** method

In addition, as you select this method, the source model screen appears in the model screen. It is the same screen as one for copying objects from an external file (see Section 2.8.7.1.1 on p. 627).

When inserting a model from the application, the source model screen is not displayed.

To set the position of a component using the **By matings** method take these steps.

1. Specify the mating objects of the current model and component on the Design Tree or in the model screen (component object can be specified in the source model screen). The names of the objects will appear in the **Assembly object** and **Component object** fields, respectively.

If you need to cancel object selection, specify it again. The **Select other** button makes it possible to cancel the selection of all objects.

2. Select a type of positioning matings by turning on the respective switch in the **Mating selection** group (the switches available depend on which objects have been selected for mating). The process of creating a matings of the set type will commence. The techniques for setting up positioning matings of different kinds are discussed in Section 2.11.4.2 on p. 706.

You can select objects for mating in the middle of the process of creating a matings.

Upon the completion of matings creation the system will return to the initial process. The created matings will be displayed on the **Matings** panel. The panel includes a matings list and list control elements.

Create the remaining matings using the same procedure.

You can include matings in the calculations or exclude them, by turning on or off respective options on the list.

To change the parameters of a matings, select it on the list and click the **Edit** button. The matings editing process will commence. Make necessary changes and click the **Create object** button on the Advanced Control Panel.

To delete a matings, select it on the list and click **Delete**.

2.11.2.5.3. Component base element

You can change the position of the component in the model using a special tool: **base element**.

The base element coincides with the component's current coordinate system. The element consists of three 3D arrows of red, green and blue corresponding to the positive directions of the X, Y, Z axes of this coordinate system. Arcs of respective colors are shown on the planes that are perpendicular to the arrows. For example, the axis X arrow is red. The arc on the plane that is perpendicular to the arrow is also red. The central point of the element is given as a sphere. An overview of a base element is shown in Fig. 2.11.3.

Fig. 2.11.3. Base element

To activate the base element select its arrow or arc. You can select an arrow when an axis icon appear next to the pointer. The rotation icon next to the pointer indicates that you can select an arc.

You can modify the base element's size. To do so, hover the cursor over it and press `<Alt> + <Ctrl> + <Shift>`. Then, keeping the keys pressed, rotate the mouse wheel. The resulting size of the base element will be saved in the system.

You can change a component's position in the model by moving and/or rotating the base element.

▼ Base element movement

- ▼ Along the axis any distance.
Move the cursor to the respective arrow, hold down the left button of the mouse and move the pointer along the selected axis in the appropriate direction. When the base element is in the correct position, release the button.
- ▼ Along the axis at any distance.
Click the arrow that correspond to the required axis. A distance input field will appear on the screen. Type the required value and press `<Enter>`. The base element will move the set distance along the selected axis.
- ▼ Moving in any direction.
Move the cursor to the sphere in the center of element, hold down the left button of the mouse and move the pointer in the required direction. When the base element is in the correct position, release the button.

▼ Base element rotation

- ▼ Around the axis to any angle.
Move the cursor to the arc on the plane that is perpendicular to the required axis. Hold down the left button of the mouse and rotate the coordinate system around the selected axis in the required direction. When the base element is in the correct position, release the button.
- ▼ Around the axis to a predefined angle.
Click the arc on the plane that is perpendicular to the required axis. A angle input field will appear on the screen. Type the required value and press `<Enter>`. The base element will rotate for the set angle around the selected axis.
- ▼ Around the axis with a set step.
Hold down `<Ctrl>` and click the arc on the plane that is perpendicular to the required axis. The base element will rotate one preset step.
If you need to rotate the base element a preset step in the opposite direction, click the arc while holding down `<Ctrl> + <Shift>`.

The step is set in preferences (see Section 9.1.11.5 on p. 1728). By default, it is 15°.

- ▼ Rotating the axis 180°.
 - Click the arrow that correspond to the required axis while holding down **<Ctrl>** or **<Ctrl> + <Shift>**. The axis will rotate 180° around one of two other axes of the base element.
 - While holding down **<Ctrl>**:
 - ▼ X axis around Z axis,
 - ▼ Y axis around X axis,
 - ▼ Z axis around Y axis.
 - While holding down **<Ctrl> + <Shift>**:
 - ▼ X axis around Y axis,
 - ▼ Y axis around Z axis,
 - ▼ Z axis around X axis.

2.11.3. Moving and rotating components

When inserting a component or after inserting it, you can use special commands to set the component's position and orientation in the model, as well as define its position with respect to other components.

KOMPAS-3D has a few methods of moving components within the coordinate system of the model that contains them. You can rotate a component about the center of its outline parallel-epiped, about an axis or about a point, as well as move it in any direction. In order to perform any other rotations of the component, the **Rotate component** command is used. The **Move component** command is used to move the component. The commands can be found in the **Service** menu, and the buttons to call them — on the **Assembly editing** panel.

When working with a part (*.m3d), component movement commands are only available on the **Assembly editing** panel. To display it, use the following command **View — Toolbars — Assembly editing**.

Note the following features when moving a component.

- ▼ A fixed component (see Section 2.11.3.4 on p. 702) cannot be moved in the coordinate system of the model that contains it. In the Design Tree, a fixed component is marked with letter **f** in parentheses.
- ▼ A component's movement may be restricted or prohibited by mates applied to this component (for more information about mates, see Section 2.11.4 on p. 703).
 - ▼ If the component can be moved (such as coaxial components that can be moved along their common axis and rotated about it), it shall be marked with a minus (“-”) sign in parentheses in the Design Tree.

- ▼ If the component cannot be moved (such as a component, coordinate planes of which correspond to coordinate planes of the assembly, so it cannot be moved or rotated), it shall be marked with a plus sign in parentheses in the Design Tree.

After any movement of a component its icon on the Design Tree is marked with a red check mark. This is an indication that the model needs to be rebuilt. To rebuild the model, call the command **View — Rebuild**. For more details about rebuilding models, see Section 2.14.3.7 on p. 795.

One should differentiate between commands for moving components within the model's coordinate system and those for moving the whole model within the screen (see Section 2.1.3 on p. 117).

2.11.3.1. Component Move

To shift a component, call the command **Move component**.

The shape of the cursor will change.

Place the cursor over the component to be moved, click the left mouse button and, while holding it, move the cursor. The component shall move in the same direction. When the desired component position is reached, release the mouse button.

The **Modes** group of switches makes it possible to perform the following:

- ▼ **Simple movement** — movement without additional operations,
- ▼ **Auto matings** — movement with automatic application of matings (see Section 2.11.3.3.1 on p. 700),

- ▼ **Detect Collisions** — movement with detection of components' collisions (see Section 2.11.3.3.2 on p. 700).

To exit from any command of component shift, press the <Esc> key or the **Interrupt command** button on the Advanced Control Panel.

2.11.3.2. Component Rotation

In order to rotate a component, call the **Rotate component** command.

The shape of the cursor will change.

You can rotate a component as follows:

- ▼ around the center of the outline parallelepiped of the component,
- ▼ around a point — a vertex, the origin of a coordinate system, or a point in the sketch,
- ▼ around a straight object — a construction axis, edge, or a line in the sketch.

By default, the component is rotated around the center of the outline parallelepiped.

In order to rotate a component around a point or straight object, activate the **Center/Axis of revolution** switch and specify the required object in the Design Tree or in the model window.

Place the cursor over the component to be rotated, click the left mouse button in the model window and, while holding it, drag the cursor. The component will rotate about the selected element.

The **Modes** group of switches makes it possible to perform the following:

- ▼ **Simple rotation** — rotation without additional operations,

- ▼ **Auto matings** — rotation with automatic application of matings (see Section 2.11.3.3.1 on p. 700),

- ▼ **Detect Collisions** — rotation with detection of components' collisions (see Section 2.11.3.3.2 on p. 700).

To exit from any command of component rotation, press the <Esc> key or the **Interrupt command** button on the Advanced Control Panel.

2.11.3.3. Additional component movement options

When moving a component using any method (shift or rotation), the following options are available:

- ▼ automatic application of matings to the elements of components,
- ▼ detection of components' collisions.

These options are only available for components that are fully loaded to the model, i.e. having the **Full** load mode (see Section 2.12.2.1 on p. 731).

2.11.3.3.1. Automatic Mating in the Process Displacement

When shifting or rotating an assembly component, you can use the automatic mating mode. This mode allows to identify the approaching elements on the components moved towards each other (such as faces, vertices, edges) and automatically add mates corresponding to their shape and type.

The mode of automatic mating is enabled after calling the command for displacing the component.

In order to enable the mode to automatically apply matings, go to the **Modes** group of the Properties bar and activate the **Auto matings** switch.

Move the component. When it approaches the other component, those faces, which can be automatically mated, will be highlighted. If you release the button of the mouse at the moment, when faces are highlighted, then they will be mated.

For example, when two flat faces approach each other, the system on the fly applies a *Coincident* mate to them, while upon cylindrical faces approaching each other — the *Coaxial* mate.

2.11.3.3.2. Detect Collisions

When shifting or rotating an assembly component, you can use the collision detection mode. In this mode, components displacement is restricted by their shape and dimensions: the motion is possible only up to “contact” with another component.

The mode of collision detection is enabled and can be customized after calling the command to displace a component.

In order to enable the collision detection mode, activate the **Detect Collisions** switch in the **Modes** group of the Properties bar. Switches for mode setup will appear in the Properties bar.

Selection of displaced components for collision detection

Movement of a component is usually accompanied with the movement of its mated components.

To perform the collision detection only for the component being displaced, activate the switch **Displaced Component Only** in the group **Detect Collisions**.

To make the collision detection performed for any of all concurrently displaced components, activate the **All components** switch.

If the displaced component is not involved in mates, then the state of switches in the group **Detect Collisions** is of no importance.

Face Highlighting at Collision

To make the contacted faces highlighted in the model window in case of collision of the displaced component with another component in the assembly, activate switch **Enable highlighting faces at collision**.

To disable highlighting of the touching faces, activate the switch **Disable highlighting faces at collision**.

Sound Alert at Collision

To enable a sound alert when one moving component collides with another component, activate the switch **Sound alert at collision on**.

To disable a sound alert, activate the switch **Sound alert at collision off**.

Stop at collision

To make further movement in the current direction impossible if a moving component collides with another component, activate the switch **Stop at collision**. In other words, this option allows you to prevent possible intrusion of the displaced component into other components.

To allow the component to be moved after collision, activate the switch **Do not stop at collision**.

Selection of immovable components for collision detection

By default, the detection of collisions of the components being moved with all other components of the model is enabled.

You can select the particular components to detect collisions for. To do this, activate the switch **Components** and select the required components. Their names will appear in the reference table **List of Components**.

To exclude the component from the list, reselect it or highlight it in the list and click the **Delete** button or press the *<Delete>* key.

2.11.3.4. Fixation of a Component

Fixing a component makes impossible any movement of the component in the coordinate system of the model that contains it. It is recommended to fix at least one component of a model, in order to have predictable movement behavior of components when applying matings.

The first component inserted into a new model from a file and positioned using the **By coordinates** method (see Section 2.11.2.5.2 on p. 692) is fixed automatically.

To fix a component(s) in its current position:

1. Select the component(s) in the Design Tree or in the Model window.

For more details about selecting components, see Section 2.1.4.1 on p. 130.

2. Click the **Enable fixation** button on the **Edit Assembly** bar or call the respective command from the context menu.

Fixed component icons are marked in the Design Tree with the letter **f** in parentheses.

When fixing a couple of components involved in the mate, the mate will automatically be excluded from the calculation. If only one of the mated components is fixed, the mate will not be excluded from calculation.

If necessary, the mate which is automatically excluded from calculation can be included in calculation manually.

If the mate participant component's (components') fixation is disabled, the matings previously excluded from calculations will be included into the calculations again. Mating of components excluded from calculation manually will not be included in calculation automatically.

In order to disable component(s) fixation:

1. Select the component(s) in the Design Tree or in the Model window.

- Click the **Disable fixation** button on the **Edit assembly** panel or call the respective command from the context menu.

The **Enable fixation** and **Disable fixation** commands are not available for components that are array's instances.

Since the property of being fixed is one of component properties, you can use the following method to fix an individual component.

1. Select the component(s) in the Design Tree.
2. From the context menu call the **Properties command**.

In group **Fixation** on the Property bar there will be active switch **Do Not Fix Component**.

3. Activate the other switch from this group — **Fix Component**.

4. Confirm changing of the component properties by clicking the button **Create Object**.

To disable fixation of a particular component, you can use switch **Do Not Fix Component** on the Property Bar.

Note that fixation can be enabled and disabled only for components of the first level of the model being modified. Thus, when working with an assembly, for instance, you can enable or disable fixation for a component contained by this assembly, not by its subassemblies. Likewise, when modifying a subassembly 'in place', you can enable or disable fixation for a component contained by this subassembly. You cannot do the same for a component contained by another subassembly or the assembly.

2.11.4. Mating components

Once all required objects have been created in the model, you can proceed with creating matings.

Matings is a relation between assembly components and objects.

For example, after application of the *Parallelity* mate on faces of two different components, these components become mated. Position of components shall change so that these faces become parallel. Herein after, once any of mated components is moved, the second component moves automatically in order to maintain parallelism of faces.

Various objects can be mated, both belonging to components, and the model that contains them: coordinate planes and axes, coordinate origins, facets, edges, vertices of bodies and surfaces, points, vertices of curves, segments of polylines, graphics objects in sketches, as well as construction axes and surfaces and local coordinate systems.

KOMPAS-3D supports mates of the following types:

- ▼ **Positioning matings** (fixing an object with respect to another object in a certain way):
 - ▼ Coincident,
 - ▼ Tangency,
 - ▼ Coaxial,
 - ▼ Parallel,
 - ▼ Perpendicular,
 - ▼ Placing elements at specified distance,
 - ▼ Placing Elements at Specified Angle;
- ▼ **Mechanical matings** (determines the rule of moving an object with respect to another object when one of them is moved):
 - ▼ Rotation– rotation,
 - ▼ Rotation– move,
 - ▼ Cam– pusher.

Commands to apply positioning mates are available in the menu **Operations— Component Mates**, mechanical mates— in the menu **Operations— Mechanical Component Mates**. Buttons to call these commands are on panel **Mates** (Fig. 2.11.4).

Fig. 2.11.4. Panel **Mates**

When working with a part (*.m3d) component mating commands are available on the **Matings** panel only. To display it, use the command **View – Toolbox – Matings**.

2.11.4.1. General Information about Mates

Positioning matings are, typically, applied during product setup. For more information about creation of positioning mates see Sections 2.11.4.2.1–2.11.4.2.8 on p. 710.

Positioning matings can be applied automatically while moving components. For more information about automatic mating see Section 2.11.3.3.1 on p. 700.

Mechanical mates are auxiliary mates applied for preliminary evaluations and visualization of mechanism operations. For more information about mechanical mates see Sections 2.11.4.3.2–2.11.4.3.5.

Both mate types can be independently applied, edited or deleted. Viewing mechanical mates can be restricted by some existing positioning mates. Therefore, mechanical mating is recommended after the positioning ones.

During creation of matings in the model, variables corresponding to these matings' parameters are created automatically. For more details about creating and using variables, see Section 7.1 on p. 1569.

2.11.4.1.1. Mate Objects

Matings are applied to paired objects, one of which is a component. The same objects may participate in several mates; it is also possible to apply multiple mates onto the same pair of objects.

Initially — right after having been inserted into a model— a component can move freely in its coordinate system.

As a result of applying a positioning mate, a component's number of degrees of freedom is decreased. For example, if you set coincidence of a part face with a plane, then this part shall only have three degrees of freedom: two degrees of freedom - for displacement, and one - for rotation.

The first component inserted into a model from a file is fixed automatically. If required, you may fix any other components, or cancel any component fixation (see Section 2.11.3.4 on p. 702).

After all positioning matings are applied, it is recommended to fix assembly components in the model coordinate system.

If in your future work you plan to apply mechanical mates, the positioning mates shall be applied in such a way that the objects could have the required degrees of freedom.

The Design Tree uses the following symbols which indicate whether a component may move in the model coordinate system:

- (f) — fixed component,
- (+) — a component with fully defined positioning matings, i.e. having no freedom degree in the model coordinate system,
- (-) — not fully defined component.

A definition is added before a component's name.

The root object of the Tree, the *Components* section, its group or a branch of identical objects have the (+) sign in front of their names, if all objects included in them are fixed or fully defined. In other cases, they have the (-) sign.

Besides fixed and fully defined components, the following objects also remain fixed in the model coordinate system:

- ▼ objects belonging to the model on the whole, not one of its components (these objects are found on the first level on the Design Tree)
- ▼ array instance.

Instances of the array being, in turn, the instance of another array cannot be involved in mates.

If one of two mated components is fixed, then the other component mobility (and, therefore, it's further mating ability with other objects) is more limited, as opposed to it's mating with a "free" component.

It is impossible to mate two fixed objects (in some cases, the mate is created and marked immediately as "error"). For example, you cannot set coincidence of two axes, which are assembly elements, even though they pass through edges or vertices of different parts. It is also impossible to mate objects that belong to the same component: this requires objects in the component to be independently moved, while this component moves as an integral array in the model coordinate system.

2.11.4.1.2. Interaction of Mates

Having applied the positioning mate, the objects shall move automatically in order to satisfy the mate conditions (provided that this condition was not satisfied prior to mate application).

Following the application of mechanical mate, the objects remain fixed (except for the **Cam - Pusher** mate, in which the previously non-contacting objects should automatically be pushed to contact each other).

Mechanical mates work within the "boundaries" defined by positioning mates. The matings' effect can be checked by moving a component in different directions. For more information about mechanical mates see Section 2.11.4.3.6 on p. 718.

While editing a model, mating inconsistencies may occur. For example, you may find that two positioning mates require different positions for the same component. Should this occur, the mating is marked as an “error” in the Model Tree.

If a positioning mate prevents any moves of the component in the direction defined by the mechanical mate, this mechanical mate shall not have any effects. The error symbol shall not appear in the Design Tree.

2.11.4.1.3. Mate Display in the Design Tree

Once a mate is created, it's icon appears in the Design Tree.

Fig. 2.11.5. Group of mates between Body and Adapter

If the display of the model structure is enabled in the Tree (see Section 2.1.2.2 on p. 106), then two or more mates, created for one and the same couple of components, shall compose a group in the “Mates” Section (Fig.2.11.5). The name of the group is generated from the names of mated components.

2.11.4.2. Positioning matings

As a rule, positioning matings exist in any model, as use of other methods (e.g. displacing the components by mouse, snapping under insertion and other) hardly allows positioning of the assembly components as required, and also, while editing unmated objects, their relative position can be easily broken.

For example, two components were somehow positioned in such a way that two their faces coincided. After changing the extrusion depth of an element belonging to one of the components, the face, with which the face of the latter component has coincided, was displaced. If faces were aligned “manually”, their relative position will be broken. The non-edited component shall remain in it's place. You shall need to reset it into the required position. If coincidence of the faces has been reached by creating components mate of type **Coincidence**, then, after editing one of the mated components and rebuilding the assembly, such a displacement of the latter component shall occur as to keep within the mate condition, so the faces, involved in the mate **Coincidence**, shall be still positioned in one plane.

2.11.4.2.1. General Methods to Create Positioning Mates

To create a mate, call the command corresponding to the required type of mating. Select the mated objects in the model window.

The distance or angle between mated faces is required to be set in commands **At Distance** and **At Angle** respectively.

After selection the objects and setup of all the parameters of mating, confirm its creation.

For the rest of commands, the automated object creation is provided. If the automated mate creation is enabled, the mates are created after the respective objects are specified. The automatic and manual object creation is detailed in Section 1.4.2.10 on p. 93.

If some elements were selected in the Model window before calling the mating command, the mate will be applied to those objects.

Orientation of Components

By default, the mating components are moved in such a way as to satisfy the mate condition, and value of the components displacement, with respect to its original position, shall be minimal. Meanwhile, the position of the components may differ from the required one. For instance, when mating *Coincidence* on the flat faces of parts is done, these parts appear on one side from the plane of the selected faces instead, as the requirement was, of being on different sides from the plane.

To control the position of mating components, disable the mode of automatic confirmation of command **Auto Create** execution on the Special Control Panel).

Then activate one of the switches in the group **Orientation** — **Direct Orientation** or **Reverse Orientation**. Position of mating components can be evaluated by the ghost in the model window.

When the desired orientation of components is achieved, confirm creation of mate.

Additional Methods

- ▼ It is possible to make several similar mates without leaving the current command. For instance, through enabling command **At Distance**, you can place two faces at the specified distance, then, having changed, if needed, the distance specify a vertex and an edge for mating and so on.
- ▼ While mating, you can use command **Remember Status**. For example: you need to position several components in such a way, so that they would touch any surface. After calling the command **Tangency** select this surface, click the button **Remember Status** on the Special Control Panel and select the required components.
- ▼ *Mates can be applied automatically in the process of moving or rotation of the component (see Section 2.11.3.3.1 on p. 700).

2.11.4.2.2. Coincident

To setup coincidence of objects, call the command **Coincident**.

Specify the first and the second objects (faces, edges, vertices, etc. in any combination), which you need to be matched.

Coincidence of coordinate systems of two components means coincidence of axes and planes of the same name of these coordinate systems. Thus, once these components are applied with such mate, they become fixed with respect to each other. Coordinate systems are specified in the Design Tree.

2.11.4.2.3. Coaxial

To setup coaxiality of objects, call the command **Coaxial**.

Specify the first and the second objects (axes, conical faces, etc.), which you want to make coaxial.

2.11.4.2.4. Parallel

To setup parallel of objects, call the command **Parallel**.

Specify the first and the second object (faces, edges, etc.), parallelism of which you want to determine.

2.11.4.2.5. Perpendicular

To set selected objects perpendicular to each other, call the command **Perpendicular**.

Specify the first and the second object (faces, edges, etc.), perpendicularity of which you want to determine.

2.11.4.2.6. Placing objects at specified distance

To position the objects at the specified distance from each other, call the command **At Distance**.

Specify the first and the second objects (faces, edges, vertices, etc.), which are required to position at the specified distance.

Closest Solution

By default, the option **Closest Solution** is enabled on the Property Bar. Therewith, the distance between the selected objects is defined automatically. Mate is created with the use of this distance.

As a result, the position of components after mating does not change or changes minimally.

Thus, for example, if a vertex and a plane were selected to apply an **At Distance** mate, then their positions will not change.

If, however, two planes were selected to apply an **At Distance** mate, then one of them will change its position to become parallel to the other. In this case, the system will choose the closest to original orientation of the displaced component. A mate will be generated using the distance, at which the planes will be situated.

The distance calculated automatically can be changed by the user.

Setup of an Arbitrary Distance

You can set a distance between the mated components prior to specifying objects. To do this, disable the option **Closest Solution** and enter the desired value into the **Distance** field.

To specify, to which side with respect to the first object the distance is plotted, activate the switch **Direct Direction** or **Reverse Direction** in the group **Direction**.

2.11.4.2.7. Arrangement of Objects at an Angle to Each Other

To position the elements at the specified angle, call the command **At Angle**.

To create this type of mating, you can use different objects. Depending on their combination, the mating angle is:

- ▼ for the rectilinear objects— the angle between crossing or intersecting straights containing these objects,
- ▼ for a rectilinear object and a plain object— angle between the rectilinear object and its projection on the plain object,
- ▼ for two plain objects— angle between the planes of the objects,
- ▼ for a rectilinear object and a rotary surface— angle between the object and the axis of rotary surface,
- ▼ for a flat object and rotation surface— angle between the rotation surface axis and its projection on the flat object,
- ▼ for two rotary surfaces— angle between the axes of rotation.

Straight and flat objects are listed in Table 2.1.7 on p. 131. Cylindrical, conical and toroidal rotation surfaces can be used for creation of this type of mating.

There may be two types of mating angles— **3D** and **Flat**.

To select the required type of the mating angle, enable the respective switch in the respective switch in the **Angle type** group of elements— **Spacial (3D) angle** for **Flat (2D) angle**.

When selecting the mating angle type, note that changing the mated components' position will be restricted after mating:

- ▼ if the angle is of the **3D** type— by the value of the angle,
- ▼ if the angle of the **2D** type— by the value of the angle and by its measuring plane position.

3D type of angle

If the **3D** type of angle is selected, specify objects to be mated. The **Angle** field will then become available for entering the mating angle value.

if the **Closest solution** option is enabled in the property bar, the value of the mating angle (angle between specified objects) is defined automatically and entered in the **Angle** field. You can use this or another value to create a mating. In the first case, the position of components after mating does not change. In the second case, the position of one of the components will be changed in accordance with the set value.

If necessary, you can set the mating angle value prior to specifying mated objects. To do so, disable the **Closest solution** option.

2D type of angle

If the **2D** type of angle is selected, specify mated objects and the axis which defines the direction of measuring the mating angle on the plane. The plane of the mating angle measuring (abbreviated— angle plane) is a conditional plane perpendicular to a given axis.

- ▼ **The axis must meet the following requirements:**
 - ▼ The object which defines the axis must be part of one of the mated components.

- ▼ If a component's surface is the mated object, the axis must be parallel to this surface or be part of it; if the mated object is an edge, then the axis must be perpendicular to this edge.
- ▼ **To define axis, the following objects can be specified:**
 - ▼ straight-line object— this object becomes the axis,
 - ▼ flat object— a normal to the flat object becomes the axis,
 - ▼ flat curve (curve, circle, sketch line)— a normal to the curve's plane will be the axis,
 - ▼ rotation surface (cylindrical, conical, toroid)— the rotation surface will be the axis.

For example, the component's mated object is its surface. As an object which defines the axis you can select an edge of the surface.

Once the axis is set, one of the mated components changes its position so that the mating angle sides are parallel to the measurement plane of the angle.

Once the mated objects and the axis are specified, the **Angle** field will then become available for entering the mating angle value. If necessary, you can set the mating angle value prior to specifying mated objects and the axis. To do so, disable the **Closest solution** option on the property bar.

If the **Closest solution** option is enabled, the value of the mating angle (angle between specified objects) is defined automatically and entered in the **Angle** field. Using this value allows to set the mating for mutual position of components to coincide with the initial or there is a minimal difference between them.

You can edit the automatically defined value of the mating angle in the **Angle** field.

2.11.4.2.8. Tangency

To set tangency of objects, call the **Tangency** command.

If you create a mate for those objects having only the *Tangency* mate option, for example, straight edge or cylindrical surface, specify these objects (edge and surface).

While creating objects in automated mode (button **Auto Create** on the Special Control Panel is pressed), a new mate created automatically shall be the closest to the objects' initial positions.

If you mate conical, spherical, toroidal faces, as well as other elements for which several tangency options are available, release the **Auto Create button**.

Specify the first and the second objects (face, edge, surface), which tangency is to be defined.

The following tangency types will be available:

- ▼ by circle— when mating with a toroid, round edge, etc.,
 - ▼ by the generatrix— when mating with a cylindrical or conical surfaces,
 - ▼ in the point— when mating with a spherical surface and tangencing two cylindrical surfaces.
- Once the second object is specified, the object tangency type is determined automatically and either **By Circle** or **By Generatrix** option is enabled. If both of these two options are disabled - the tangency is provided in the point. You can't change status of these options.

Exceptions are the following pairs of objects:

- ▼ *cylinder*— *cylinder* (in the point, by the generatrix);

- ▼ *cone– sphere* (in the point, by the circle).

To set a tangency type for objects of these pairs, enable or disable the respective option.

After selecting objects, the components will be displayed on screen as follows. In case of the by circle **tangency** - the coinciding circles will be in the common plane. In case of the tangency by the **generatrix** - the generatrices will be positioned on the same straight line. In case of the tangency **in the point** - the objects will have a common point.

In a *sphere – toroid* pair, a specific tangency type is possible — in the points of external and internal equatorial circles of the toroid. Such type is considered a circumference tangency.

For plane, cylindrical, cone, non-closed toroidal and spherical faces the tangency line or point may appear on the face extension.

If two mate options are possible, switches of the Orientation **group are available**. To change orientation click either **Direct orientation** or **Reverse Orientation** switch. If more than two mate options are available, button **Next** will be available instead of the orientation switch. After clicking the button, the next option is displayed.

To display other tangency type options for *cylinder– cylinder* and *cone– sphere* pairs of objects, enable the respective option and proceed with viewing.

Once you have selected a mate option, confirm its creation.

2.11.4.3. Mechanical Mates

Mechanical mates ensure relation of components moving in the mechanical transmissions, reducing gears, cam mechanisms and other models. Mechanical mates allow to shift a designed mechanism to various positions by moving one of it's components. While changing this component position, other mated components also move (but with respect to the restrictions applied by positioning mates).

Fig. 2.11.6. Example of parts mated movements

When creating mates, the following issues shall be accounted.

- ▼ Mechanical mates are applied to paired objects similar to positioning mates. The following types of mechanical mates and corresponding movement types are available:

- ▼ **Rotation– Rotation** Both objects rotate.
- ▼ **Rotation– Move** One object rotates, while another — moves along the straight line path.
- ▼ **Cam – Pusher.** One object (cam) rotates while the other (pusher)— moves along the straight path with the contact between the cam and pusher maintained.
- ▼ Several mechanical matings can be created in one model. The same component can be mechanically mated with several components.

In the example illustrated by Fig. 2.11.6, wheels 1 and 2 rotate when wheel 3 is moved along the bar 5. It is ensured by matings **Rotation – move** assigned to wheel 3 - bar 5, wheel 2 - bar 5 and mating **Rotation – rotation** assigned to wheels 1 and 2.

To view operation of a complicated mechanism (if there is no need to show movements of all its parts) it shall be sufficient to setup mates between the first and the last movable elements. In the example, illustrated by Fig. 2.11.6, it might be the **Rotation – move** mate assigned to wheel 1 and part 5. When part 5 is moved, wheel 1 rotates while wheels 2 and 3 do not rotate.

No contact between parts is required to create the **Rotation– rotation**, **Rotation– move** mates and view their operation.

- ▼ When demonstrating mechanical matings, all positioning matings used in setting up a model restrict spatial motions of components. When applying positioning mates, make sure that the components have degrees of freedom to allow for further application and work of mechanical mates (see section 2.11.4.3.1).

2.11.4.3.1. Providing correct work of mechanical mates

To ensure the expected relative relocation of the components bound with a mechanical mate, it is recommended that these components have minimal number of degrees of freedom that are necessary to move within mechanical mates. You can decrease the number of degrees of component freedom using positioning mates with other objects as well as using fixing.

As a rule, if positioning matings are applied in a model so that components have as many degrees of freedom as parts and nodes in a real structure, you do not need to impose additional restrictions to provide work of mechanical matings.

Let us illustrate the above-said by examples.

1. Rotation – Rotation

Let us consider the mate between two gear wheels in which the wheels must rotate about fixed axes (e.g. the wheels 1 and 2 in Fig.2.11.7 on p. 715).

Make sure of the following prior to mechanical mating:

- ▼ the axes are fixed in the model coordinate system,
- ▼ the wheels and their respective axes are coaxial.

Usually, wheels cannot move along rotation axes. You can achieve this by binding flat end faces of wheels to some fixed flat object with the **Coincidence** mate or **At Distance** mate.

So, each wheel will have one degree of freedom to rotate about an axis.

After you apply the **Rotation – Rotation** mate, the rotation of any wheel will result in rotation of another wheel.

Note that wheel rotation axes must be fixed for this particular example. In other cases, axes can move, e.g. satellite wheel axes in planetary drives.

2. Rotation – Move

Example 1. Let us consider the mate between a wheel and bar, in which the wheel must move the bar while rotating (for example, see Fig. 2.11.8 on p. 716).

Make sure of the following prior to mechanical mating:

- ▼ the wheel axis is fixed in the model coordinate system,
- ▼ the wheel and axis are coaxial,
- ▼ the bar is permanently oriented to the wheel axis (you can do this in a variety of ways, e.g. by binding straight edge of the bar to one fixed plane with mate **At Distance** and the other — with mate **Coincidence**).

As in previous example, you can apply the mate preventing displacement of the wheel along the axis.

So, the wheel will have one degree of freedom to rotate about its axis and the bar will have one degree of freedom of translational motion.

After you apply the **Rotation – Move** mate, rotation of the wheel will result in movement of the bar and vice versa - movement of the bar will result in rotation of the wheel.

Example 2. Let us consider the mate between a screw and a nut, in which the screw must move the nut while rotating.

Make sure of the following prior to mechanical mating:

- ▼ the screw cannot move along the rotation axis,
- ▼ the screw and the nut are coaxial.

So, the screw will have one degree of freedom to rotate about the axis and the nut will have two degrees of freedom: to rotate about the axis and move along it.

After you apply the **Rotation – Move** mate, rotation of the screw will result in movement of the nut and vice versa - movement of the nut will result in rotation of the screw.

The screw can be also fixed in this mate. Then, the nut will rotate while moving. But if both the screw and the nut will have two degrees of freedom (to rotate and move), correct work of the mate becomes impossible.

3. Cam – Pusher

Let us consider a mate, in which a cam must move a pusher along the straight path while rotating (for example, as in Fig.2.11.9 on p. 717).

Make sure of the following prior to mechanical mating:

- ▼ the cam rotation axis is fixed in the model coordinate system,

- ▼ the pusher is permanently oriented to its movement path (you can do this in a variety of ways, e.g. by aligning the pusher with the fixed axis if it has circular section).

Working surfaces of the cam and pusher automatically contact each other after you apply the **Cam – Pusher** mate by moving the pusher along its path. Make sure that the shape and relative position of the cam and pusher as well as the mates applied to them do not prevent this. There is no need to apply the **Tangency** mate to the cam and pusher.

We recommend to apply the mates to the cam that prevent its displacement along the rotation axis to keep contact of the cam with the pusher.

So, the cam will have one degree of freedom to rotate about the axis and the pusher will have one degree of freedom to move forward. It does not matter if the pusher has the degree of freedom to rotate about the path.

After you apply the **Cam – Pusher** mate, rotation of the cam will result in movement of the pusher. Inverse movement transfer - from the pusher to the cam - is not provided for in the **Cam Pusher** mate.

2.11.4.3.2. General Methods for Creating Mechanical Mates

To create a mate, call the command corresponding to the required type of mating.

Specify the first of the mated objects in the Design Tree or in the Model window: Specify the object's rotation axis or moving direction path.

Complete the same procedures for the second object.

As for the **Cam – pusher** mate, there are specific issues on object selection. They are described in the Section 2.11.4.3.5 on p. 717.

The specified objects shall be highlighted, and their names shall appear in the respective field of the Property Bar.

Specification of objects, axes and paths is performed after clicking the switch located next to the object field on the Property Bar.

You may cancel currently specified object by clicking the **Specify Other** button on the Special Control Panel.

If required, change relative moving direction of objects. See the following text for more details on how to select directions.

Depending on a transmission type, set the correlation of movements in the **Correlation** field. The value can be input from the keyboard or selected from the drop-down list of correlations previously used in the KOMPAS-3D current operation session.

Once you set up parameters, confirm mate creation.

object selection

Pairs of objects are composed of the components, and one of them can be fixed. In addition, a component can be mated with some other object in the model.

In order to specify rotation axes and movement paths you may select the following objects.

- ▼ Straight lined (segments of polylines, coordinate and auxiliary axes, straight edges).

An axis or path is the line which coincides with the object.

▼ Planar curves (arc, circle-type edges).

An axis or path is the line which passes through the center of the specified object perpendicular to its plane.

▼ Revolution surface faces (cylindrical, cone, toroidal).

The rotation axis is the axis or path.

When specifying some elements along with the object to which these elements belong, the axis or movement path will be selected by default. Its name appears in the corresponding field (**Axis**, **Axis 1**, **Axis 2**, **Path**) of the Property Bar.

For example: an edge of the mated part was specified for its selection for mating. The **Component** field will display the name of this part, and name of the specified edge shall appear in the **Path** field.

Length of displacement along the path is not limited by the specified object length.

Moving Direction

When specifying an axis or path, the system automatically sets the direction of objects movement in the transmission. In the Model Tree, the rotation direction is marked with round arrows, movement/displacement direction - with straight arrow.

Automatically set directions can be changed by group switches **Direction 1** — for the first object and **Direction 2** — for the second.

Only relative direction of mated objects motion is accounted— while viewing transmission each object can be dragged by mouse in both directions - **forward** and **backward**. Herewith, the object moving directions either coincide with the preset one, or are opposite.

For example, if you require wheels of the wheel gearing to rotate towards each other, set opposite directions for these objects (to do this: set switch **Straight Direction** for one object, and **Reverse Direction** for another).

2.11.4.3.3. Rotation– rotation mate

The mate is used to visualize movements in gear, belt, chain, frictional transmissions and other models. To create this mate call the **Rotation - rotation** command.

Fig. 2.11.7. Example of Applying Rotation Mates

Specify the first object and the axis to rotate about and then the second object and its rotation axis.

You can specify mated objects by selecting them prior to calling the command.

Set direction and correlation of movements.

Correlation of movements defines ratio of the first object's number of revolutions to the same of the second object. This ratio is determined similar to the gearing ratio. Relation 1:2 means that during one revolution of object 1, object 2 makes two revolutions.

If one of the objects is fixed, the calculations shall be carried out following the same procedure. For example, let one of two mated wheels to be fixed. In this case the moving wheel makes a complicated rotative motion— it rotates about its axis, and at the same time - about the fixed wheel. Correlation shall be presented as the ratio of the number of revolutions of movable axis around the fixed one to the number of revolutions of fixed wheel around it's axis.

When specifying rotation surface, it's radius is entered by default in the **Correlation** field.

You may select parameters for two revolution surfaces by clicking on these surfaces.

The example in Figure 2.11.7 shows how you can apply two rotation mates— between wheels 1 and 2 and between wheels 3 and 4.

It is impossible to apply the mate onto pair of objects on the same rotation axis. Such objects - wheels 2 and 3 - are illustrated in Figure 2.11.7.

2.11.4.3.4. Rotation – movement mate

This mate allows to visualize movements in rack-and-gear transmissions, screw-and-nut assemblies and other models. To create the mate, call the **Rotation – move** command.

Fig. 2.11.8. Example of use of the Rotation– movement mate

Indicate the first object and the axis to rotate about and then the second object and the path specifying direction of its movement.

You can specify mated objects by selecting them prior to calling the command.

Set direction and correlation of movements.

Correlation of movements defines the ratio of the single radius circumference (2π mm) to linear displacement of the second object.

Relation 1:2 means that during one revolution of object 1, object 2 moves by $2 \cdot 2\pi$ (mm), i.e. about 13 mm.

If one of the objects is fixed, the calculations shall be carried out following the same procedure. For example: let the bar is fixed, the wheel of radius R (mm) moves along it without sliding. During one revolution of the wheel the bar moves by $2\pi R$ with respect to the wheel center. Displacement ratio is 1: R .

You can calculate the required correlation using by the following formula: $1:(L/2\pi)$.

Where L — is a distance in mm the second object will pass per one revolution of the first object.

2.11.4.3.5. Cam – pusher Mate

The mate is used to visualize movements in cam mechanism. To create this mate, call the **Cam – pusher** command. The cum makes a rotary motion, while the pusher goes backward and forward. Here the pusher operating surface remains contacting the cum operating surface.

Fig. 2.11.9. Example of the Cam-Pusher Mate

Mated Objects

The mate objects shall be selected so as one of them would function as a cum, rotating about the axis, while another shall be a pusher moving along a straight path. The mechanism structure shall ensure that cam contacts pusher within their respective working surfaces.

The **cam** model shall be a single-body part.

The cam's working surface may comprise one or several faces— flat, cylindrical, cone, toroidal. Moreover, the cam working surface may look like a ruled surface, whose sketch consists of lines, arcs, ellipse arcs, splines.

In order to specify a **cum rotation axis**, you may select the following objects.

- ▼ Straight lined (segments of polylines, coordinate and auxiliary axes, straight edges).
An axis is the line which coincide with the object.
- ▼ Planar curves (arc, circle-type edges).
An axis is the line which passes the specified object center along the normal with respect to its plane.
- ▼ Revolution surface faces (cylindrical, cone, toroidal).
The rotation axis is the axis.
The **pusher** working surface is a flat or spherical face. The mate process engages the surface which has been generated by extending the specified face— plane or full sphere.
The pusher part top level can function also as the working surface,.

Should working surface of the pusher be flat, working surface of the cam can be a cylinder, cone or ruled surface only. Therewith, the cum and pusher shall be mutually oriented so that they could contact each other along the straight line.

Straight objects (segments of polylines, coordinate and auxiliary axes, straight edges) can be **specified as the pusher paths**. The pusher will move along the selected path.

Mate Creation

While the Cam **Faces** button is pressed, specify one by one those faces of the cam working surface, that shall be used for mating. Number of faces appears in the **Cum Faces** field.

Click the **Axis** button and specify the axis the cam will rotate about. It's name shall appear in the axis field.

If faces of the cum working surfaces are smooth-mated, selection of one of the object faces, while the **By Tangent** option is enabled, results in automatic selection of adjacent faces. Only those faces will be selected that are joint along fragments of straight lines, which are parallel to the cum axis.

Click the **Pusher Face** button to specify a working face or pusher top.

Click the Path **button and** specify the pusher movement path. It's name appears in the path field.

Once an axis or path is specified, the system shall automatically determine direction for rotation or displacement along the path. In the Model Tree, the rotation direction is marked with round arrows, movement/displacement direction - with straight arrow. The cum and pusher working surfaces start contacting.

2.11.4.3.6. Viewing Mates operation

To check or visualize mate operation, move one of mated components. Such movement shall comply with those parameters preset during mate creation. In other words, you need to select an axis to rotate and the direction preset during mate creation to move. This movement shall *initiate* displacement of the mated object— *response* displacement. In it's turn, the object's response displacement can initiate displacements of other inter-mated objects, etc.

To initiate moving a component, use the commands listed below:

▼ **Move Component,**

▼ **Rotate Component About Axis,**

▼ **Rotate Component About a Point,**

▼ **Rotate Component About the Central Point.**

For more information on model component moving commands, see Sections 2.11.3.1 – 2.11.3.2.

The initiating movement can be a part of a component's complex movement. For example: to view mate **Rotation–move** you may use the command **Rotate Component About Axis**. While dragging the bar by mouse (see Figure 2.11.8 on p. 716), the linear component of bar rotation shall serve as initial displacement. Only that linear component is accounted, which is co-directed with the mate-preset path.

If movement of an object is not initiating and has no initiating components, the mated objects shall not move in response.

You can view only those matings of the current model that are applied to this model's components and bodies.

When viewing mates, keep in mind the following conditions.

- ▼ Positioning mates can prevent change object positions.
- ▼ In order the rotary motion to be initiating, make sure that the axis, selected to complete this task, coincides with the axis preset in mechanical mate. If this axis is set automatically in the mate during specification of an object element, construct such axis as, for example, an auxiliary object.
- ▼ Direction of the initiating movement can either coincide to that one preset in the command or be reverse. All parts of mechanical transmissions shall move in accordance with relative directions preset during mate creation.
- ▼ A component's rotation or movement along the path is not limited. To avoid “penetration” of one model component to another, you may set your preview mode to the collision detection. For more information about collision detection mode, see Section 2.11.3.3.2 on p. 700.
- ▼ If any object, which sets displacement direction (e.g., edge), belongs to a movable component, the path shall change its position in space to comply with the mate conditions.
- ▼ You can create mate of movable and fixed (non-movable) objects. In this case, a movable object - if its movements are not affected by positioning mates - will do complex rotary or rotary-translation motion with respect to non-movable one.
- ▼ To preview the **Rotation – move** transmission it is important to set a relation which shows real displacement of objects. The relation calculation method is presented in Section 2.11.4.3.4 on p. 716.
- ▼ Preview of the **Cam – pusher** transmission is only possible when moving the cam. Mated move takes place only within the faces specified as its working surfaces. The cam faces, not specified in the mate, may lose contact with the pusher.

- ▼ While previewing the **Cam – pusher** transmission, the contact may be invisible since the pusher working surface is the entire spherical surface or edge plane.

2.11.5. Boolean operations on Parts

The parts (including local parts) constituting one assembly (*.a3d) can be “subtracted” from each other and “attached”.

Boolean operations with parts are performed when editing them in an assembly.

The result of a Boolean operation of subtraction is modifying the body of the part by removing cross-sections with the bodies or components of other parts from them. Components of a part are not modified by Boolean subtraction even if they cross-section with the parts being subtracted. The subtraction result is stored in the part from which other parts have been subtracted.

The result of Boolean operation of addition is a body that encompasses the bodies of other parts or their components. The result is written to a new file of the part or to a new local part.

A body can take part in a Boolean operation only in case the part it contains includes no other bodies. Components can be used in a Boolean operation regardless of their number in the part.

The result of a Boolean operation preserves connection with parts used in the operation. For example, changing the form of a part being subtracted will result in a changed form of the hollow area that results from the subtraction. Removal from the assembly of a part involved in a Boolean operation will result in the deletion of the operation, too.

2.11.5.1. Subtraction

Subtraction allows a cavity to be created in the part that has the form of another part. To subtract one or more parts from a part, enter context editing mode for the part you want to have a cavity as a result. To do so, select the part on the Design Tree and call the command **Edit in place** from the context menu.

Call the command **Operations — Subtract components**. The respective command calling button is located on the panel **Edit Part**.

Select the parts you need to subtract from the edited one.

Selected parts are highlighted in the Model window. Their respective icons will be highlighted in the Design Tree. The names of these parts are displayed in Table **List of Components** on the Property Bar.

If it is required that the sizes of the cavity to be created differ from those of the part to be subtracted, enter in the field **Coefficient** the cavity linear extension coefficient in percentage terms. To enlarge the cavity sizes, the coefficient value should be positive, to reduce — negative.

The cavity will be increased in relation to the subtracted part by $(1 + k/100)$ times, where k is specified coefficient. By default, the void scaling center is the outline box center of the part being subtracted. If necessary, you can explicitly define the scaling center. To do this, select the

desired point in the Model window with the mouse. To reject this point as the center of scaling, select it again.

Confirm execution of the operation. In the current part the cavity, having the specified shape and sizes, will be generated.

The subtracted part can have such a position and shape that after subtraction a body consisting of several parts can be produced (see Section 2.3.11 on p. 224).

On the “branch” of the Design Tree corresponding to the current part there will appear the icon of the components subtraction operation.

When finished with creation or editing the part, exit from the mode of context editing.

If necessary, you can hide or exclude from calculation the parts, used for the cavity creation.

2.11.5.2. Union

While working with the assembly, you can “merge” several existing parts and get a single part. For example, this can be required for union of the designed parts into a single cast framework subject to the new specifications arisen in the process of designing.

To unite several parts, create a new part in the assembly. To do so, use the **Operations — Create** menu to call the command **Part** or **Local part**.

The system enters the part editing mode.

Call the command **Operations — Unite Components**. The respective command calling button is located on the panel **Edit Part**.

Select the parts, which are to be united. To perform the operation, the selected parts need to intersect each other or have coincident faces.

Selected parts are highlighted in the Model window. Their respective icons will be highlighted in the Design Tree. The names of these parts are displayed in Table **List of Components** on the Property Bar.

Confirm execution of the operation. In the model window, there will appear the body of the new part which is the union of the selected assembly parts, and on the Design Tree — the corresponding icon.

Methods to work with the derived solid body do not differ from work with any other part. You can attach and cut the shape-generating elements, create fillets, drafts and so on.

When finished with creation of the part, exit the mode of context editing.

If necessary, you can hide or exclude from calculations the parts that were joined into the new part.

2.11.6. Editing components

Components are independent models inserted in the current model.

To change the geometry of a component you need to either open it in a separate window (see Section 2.11.6.1 on p. 722), or enter the context editing mode for the component (see

Section 2.11.6.2 on p. 723). This done, you can now use any editing techniques described in Section 2.14.3 on p. 786.

Please note that editing in a separate window is available for components that are a part, sub-assembly, or base part inserted with history. Local part and base part without history can be edited only in the context of the current model.

Upon completing editing the component, close its window or exit context editing mode. Edited components are normally marked with a red tick mark on the Design Tree. This is an indication that the model needs to be rebuilt. To rebuild the model, call the command **View — Rebuild**. For more details about rebuilding models, see Section 2.14.3.7 on p. 795.

If required, you can edit the properties of the component (see Section 2.11.6.4 on p. 725). When editing, the following operations are available:

- ▼ changing component properties, including color and optical properties,
- ▼ fixation control and component state (including the component into the calculations),
- ▼ setting parameters of the component's MP and conducting calculations,
- ▼ selecting another file as a component source,
- ▼ re-calculating the component's dimensions taking into account preset tolerances.

In addition, you can change the position of the component in the model (see Section 2.11.6.3 on p. 724). The following actions are available within this process:

- ▼ setting the component's position using different methods,
- ▼ fixation control and component state (including the component into the calculations),
- ▼ changing the color and optical properties of the component,
- ▼ specification object creation control,
- ▼ selecting values of the component's external variables.

2.11.6.1. Editing the geometry of the component in a window

To start editing a component in a separate window showing this component only (without other components), select the desired component in the Design Tree and use **Edit in window command**. It is recommended that before editing you save the current model.

You can proceed with editing a component in the window by opening its file in the usual way: use **File — Open** command and select the desired file. When using the **Edit in Window** command, you do not need to search for the desired file in the list — the system finds it automatically.

After calling the **Edit in window** command, the source file of this component will open. Make the desired changes to the model and save it. Then close the component window or go into the model window.

When editing a component “in window”, all objects that belong to this component are displayed and are available for editing (you can modify object parameters, their reference objects, etc.). However, editing certain elements is restricted. This includes component objects that were created in the model context using elements from other components of this model (i.e.

using elements that do not actually belong to the component being edited), such as component's auxiliary plane running through edges and/or vertices of other parts, etc.

In the component file that contains objects defined in the assembly context there are links to the file of the model (those links are called external since the assembly file is **external** with respect to the component file). When editing such a component in a separate window, the only available means is to redefine the external links to make them internal. In other words, to construct an object referencing objects from an external file, you can specify other objects available in the current file. An element edited in this way loses connection with the external file.

However, if it is required that the element defined in the model context does not lose the relation with it, then you need to edit it in the context of that model ("in place").

2.11.6.1.1. Saving component under other name

If both the model file and the source file of a component are opened simultaneously, then the system will request the user to change the link to the component when trying to save the component file under a different name or in a different folder.

- ▼ If you want the model to refer to the component file under a new name, click the **Change links** button. This may be needed, for example, for including an edited component into a model and saving its original instance.
- ▼ If you want the model to refer to a file with the old name, click the **Save links** button. This may be needed, for example, to save an edited component without transmitting its modifications to the model that contains it. Note that in this case the model will have to be closed without saving after component editing is finished.

The links are changed only in the currently open models. The links are not changed in the models that are linked to this file but are closed at the time of its saving under a different name.

2.11.6.2. Editing component geometry 'in place'

Editing "in place" (in the model context) is editing a component in the window of the model to which it belongs. At the same time, all the rest of the components are shown in the window ("the environment" or "the situation"), and the commands to shift and rotate the model, change its scale, orientation and display type are available.

It is especially convenient to edit "in place" the component objects that were constructed using "environment" (for example, an element extruded up to a face of a neighboring part, or a construction axis passing through the coordinate origin of another component). In other words, the objects that were created in the model context should preferably be edited in the context of the same model.

When editing 'in place', the updates are made directly to the component file (part or subassembly) — just as it would be if the file was opened in a separate window. The prompt to save the component file appears when editing is complete.

When editing a local part or base part without history the save file prompt does not pop up, as these are stored not in an external file, but in the file of the model that contains them.

2.11.6.2.1. Context editing mode operation

To start editing an assembly component in the current window, select the desired component in the Model Tree and use **Edit in place** command. Button for this command is on the **Current Status** bar.

The system will enter component editing mode.

The icon of the component being edited in the Model Tree becomes orange instead of blue, and the icon of the containing model becomes vice versa blue instead of orange. This indicates that the component has become the current document.

The active “in-place editing” mode is indicated by the pushed **Edit in Place** button, and the context editing mode icon in the model window.

In this mode, all construction and editing commands affect only the selected component. Other model components are not accessible for editing (serve as “background”), but they can be used when executing commands (to select faces, edges, vertices).

You can change colors for displaying components which make up the “environment” or disable change of color for these components (see Section 9.1.11.8 on p. 1732).

Techniques for creating/editing models 'in place', in the context of containing model, are virtually no difference from the ones for creating/editing models in a separate window. When working with a model you can, for example, perform shape-generating operations, create auxiliary elements, add components from file, create components 'in place', etc. Additionally, you can use it to create 'environment' elements. For instance, you can extrude a shape-generating element up to the facet of the other component, draw an axis through its vertices, create an outline on the face of an adjoining part (when working with an assembly).

To complete editing the component 'in place', use **Edit in place** command once again or release the **Edit in place** button, or click the context editing mode icon in the model window.

The system will return to main model operation mode.

2.11.6.3. Changing the position of a component

To change the position of the component in the model, select it on the Design Tree and call the command **Position Component** from the context menu or **Edit** from the **Editor** menu. The **Location** and **Properties** tabs will appear on the Properties panel. The following actions are available on these tabs.

- ▼ The **Location** tab
 - ▼ Changing the component's position in the model (see Section 2.11.2.5.2 on p. 692). The set of component positioning control elements depends on the chosen positioning method — **By coordinates** or **By matings**. The elements are available if component fixation is disabled.

If a component whose position needs to be changed is positioned in the model using the **By matings** method, note the following peculiarity.

If you switch to the other positioning method (**By coordinates**) previously created matings are not deleted from the model, but are excluded from the calculations.

If necessary, you can include the matings in the calculations. In doing so, the component's position will change accordingly to the set matings.

When editing a base part inserted without history, note that such a base part does not keep links with the source file. For this reason, if you set its position using the **By matings** method the model window does not show the source model screen.

▼ Turning on/off components fixation using switches **Fix component** and **Do not fix component** in the **Fixing** group.

▼ **Properties** tab

▼ Changing the color and optical properties of a component. Control elements used for this are described in Section 2.14.2 on p. 784.

▼ Turning on/off creating a specification object using respective option (for all components, save base parts).

▼ Including component into the calculations and excluding one. Switches in the **Status** group are used for this.

▼ Selecting new values of external variables of the model that is the source of a component, if it contains a table of variables. For this, you need to click the **Table of Variables** button and select the required row in the table that appears on the screen.

To finish changing the position of a component, click the **Create object** button on the Advanced Control Panel.

2.11.6.4. Changing component properties

To change component properties, select it on the Design Tree and call the command **Component properties** from the context menu. The **Properties**, **MP parameters** and **Source file** tabs will appear on the Properties panel. The following actions are available on these tabs.

▼ **Properties** tab

▼ Changing component properties using the **List of properties** panel (see Section 5.1.4.1.1 on p. 1385).

▼ Changing the color and optical properties of a component. Control elements used for this are described in Section 2.14.2 on p. 784.

▼ Turning on/off components fixation using switches **Fix component** and **Do not fix component** in the **Fixing** group.

▼ Including component into the calculations and excluding one. Switches in the **Status** group are used for this.

▼ **MP Parameters** Tab

- ▼ Selecting MP determination method and setting component material properties using the **Material** panel (see Section 2.14.6.3 on p. 805).
 - ▼ MP recalculation. Is carried out by clicking the **Recalculate MP** button, which results in recalculating mess-center characteristics of the component with current parameters. The Message window with the calculation results pops up when calculation is finished.
 - ▼ **Source File** Page
 - ▼ Selecting another model for insertion, as well as the model's version or additional number (see Section 2.11.6.4.1).
 - ▼ Re-calculating the component's dimensions taking into account tolerances. To do so, click the **Recalculate dimensions** button and select the required recalculation from a recalculation drop-down list (more about recalculations, see Section 2.10.3.1 on p. 672).
- To finish changing the component's properties, click the **Create object** button on the Advanced Control Panel. The model image will be redrawn and/or the model will be redrawn according to the new properties of the object.
- Note that the model has to be rebuilt if:
- ▼ the component's source file is modified, its other version or additional number is chosen,
 - ▼ component's dimensions are changed taking account of tolerance fields.

2.11.6.4.1. Changing component source

If you need to select another model as the source of the component, take the following steps on the **Source file** tab.

Click **Source file**.

Select the file, containing the required model, in the dialog appeared on screen.

If the selected model contains versions and additional numbers, you can select the required version and additional number using appropriate lists. Lists are displayed in the dialog provided the model contains versions and additional numbers.

To complete selection of the model, click **Open**. The full name of the model will appear in the **Source file** field.

If will need to reselect the version or additional number of the model later on, use the **Version** and **Additional number** lists on the **Source file** tab. Lists are displayed in the dialog provided the model contains versions and additional numbers.

For a local part or base part inserted without history you cannot select a different model, and you can select model version and additional number only in case if the insertion source was a model that contains versions and additional numbers.

2.11.6.5. Particular features of working with local parts and base parts without history

There are the following peculiarities of working with a local part and base part inserted without history as compared with other components.

- ▼ The user can control displaying objects in the Design Tree which make up the local part (base part without history). To do so, the following commands **Show structure** and **Hide structure** in its context menu. By default, a newly created local part is displayed, and base part without history is not. Controlling the display of the composition of a local part (base part without history) is similar to that of the composition of a macroelement (see Section 2.15.8.2 on p. 840).
- ▼ Local part and base part without history are not linked with **.m3d* files, but are stored in the current model. For this reason, they can be edited only in the context of the main model. The context menus of these components contain only the **Edit in place** command, while the **Edit in window** command is not available. Editing a local part and base part 'in place' is the same as editing other components (see Section 2.11.6.2 on p. 723). The only difference is as follows: when exiting the edit mode there will be no prompt to save the file.
- ▼ Local part and base part without history are always fully loaded, with **Full** loading type setup only available for them.
The remaining work techniques — shift and rotation, mating, setting properties, access control, etc. — are available as much as when working with other components.

2.12. Assembly Peculiarities

2.12.1. Background KOMPAS

A KOMPAS-3D assembly is a three-dimensional model combining models of parts, subassemblies and standardized parts along with the information about the relative position of components and dependencies between parameters of their elements.

The user defines the assembly composition by adding new components or deleting existing ones. For more details on components, see Section 2.11 on p. 683.

Two approaches to designing an assembly are used, tailored to two methods of adding a component to an assembly:

- ▼ **Bottom up** — ready component models developed independent of each other are inserted in the assembly;
- ▼ **Top to bottom** — the components are created in the context of the assembly, and the subsequent ones can be based on the preceding ones.

In real life, a mixed design method is used, i.e. a combination of the said two methods. In addition, **composition geometry** can be used— baseline data presented in the graphics form and used as a basis for creating the geometry of the components, or an assembly 'layout' of sorts, used to place the components. If you need to model movements of assembly components, i.e. show the workings of the mechanism, composition geometry can be used a mobile wireframe that set in motion the components that are linked with it.

For more details about design approaches, see Appendix VII. Design methodologies used within the approaches are discussed there as well. About working with composition geometry, see Section 2.8.6 on p. 618.

If the assembly is large enough, i.e. includes over 1000 components, it is usually developed by several developers. In addition, large assembly components often have rather complex geometry.

In connection with this, the following must be provided during work with large assemblies:

- ▼ optimized use of computer resources,
- ▼ control of access to various assembly parts when several developers work with it,
- ▼ protection of working results of one assembly developer from modifications of another developer.

The above-listed requirements can be satisfied by:

- ▼ special settings KOMPAS-3D that reduce consumed computer resources (see Section 2.12.1.1 on p. 730),
- ▼ banning changes to some of the assembly's components (see Section 2.12.3 on p. 744),
- ▼ creating assembly load modes (see Section 2.12.2.2.2 on p. 736) and protecting them with passwords (see Section 2.12.2.3 on p. 741).

Recommendations on how several developers can work with an assembly are given in Appendix VII.

The model file internal structure has been improved starting from Version 10 and higher of KOMPAS-3D. In this context, if the model is created in the KOMPAS-3D Version 9 or lower versions, we strongly recommend to save the assembly and its components in the current version.

2.12.1.1. Settings of the 3D editor to work with a large assembly

1. When working with large assemblies or use the simplified display mode for faster offset and rotation of a model. Set up the simplified display mode as follows.
 - ▼ In the dialog which is used to simplify components, reduce detalization level and enable auxiliary mode for the standardized components. If your model comprises a large number of standardized components, we recommend to disable display of these components by the **Hide option**.
 - ▼ Enable all options in the dialog which is provided to set up other parameters of the simplified mode.

For more information about display of models in simplified mode, see Section 2.1.3.6 on p. 129.

The model simplified display mode is enabled by default; there are also enabled all options in the dialog which is used to set up simplified display mode.

2. Disable all options in the Orientation Settings dialog (see Section 9.1.11.6 on p. 1731). This allows to exclude additional rotations and scaling of the model.
3. Make sure that the **Display Read-only status for components** option in the access rights setup dialog is disabled (see Section 9.1.4.2 on p. 1694). If the option is enabled, more time for the model's file opening is required due to performance of a check for components' read-only status.
4. To reduce time for model redrawing after shift or rotation, make the following settings.
 - ▼ Using commands of the **View — Hide** menu disable display of those assembly auxiliary objects that are not required now. Display in the assembly of major part of the object auxiliary components is disabled by default. If required, you may hide the rest objects using commands in the **View — Hide in Components** menu.

- ▼ Disable display of half-tone wireframe images.
5. To restore quickly the frequently used model positions, save them as customized orientations (see Section 2.1.3.2.1 on p. 123).

2.12.1.2. Settings for large assembly's associative drawings

To speed up construction of associative assembly views in a drawing, it is recommended to proceed in the following way: prior to creating associative views, make the following setting for the current drawing in the new view settings dialog (call the respective dialog using the command **Service — Parameters... — Current Drawing — Document Parameters — View**):

- ▼ on the **Parameters** tab: disable options **Hidden** and **Library**,
- ▼ On the tabs **Lines** and **Dimensions and Process Symbols**: disable all options.

Such setup shall allow you to get on the drawing only model visible contour lines.

Images of cosmetic threads, as well as images of hidden and library components can be enabled at the final stage. Cosmetic threads are enabled on tab **Dimensions and Process Symbols** of the Property bar (insertion is possible during editing); component images are enabled using the **Show** command from contextual menu for these components in the Drawing Tree.

Displaying of hidden lines, tangent edges and bend lines can be activated in tab **Lines** on the Property Bar (activation of this displaying mode is possible during view editing). However, when working with assemblies comprising over 1000 parts, it is not recommended to enable transfer to the view of hidden lines, otherwise it would essentially increase the time required to construct and reconstruct views.

The model file internal structure has been improved starting from Version 10 and higher of KOMPAS-3D. In this context, if the assembly model is created in the KOMPAS-3D Version 9 or lower versions, we strongly recommend to save the assembly and its components in the current version. This should speed up construction of views and transfer of mass value from the model file to the drawing title block.

2.12.2. Partial assembly loading

Partial assembly loading means temporary presentation of chosen components in a simplified, unloaded view or as outline boxes.

The user assigns loading types to components (see Section 2.12.2.1.6 on p. 733) and thus creates the assembly loading type. Assembly loading types are different combinations of components' loading types saved in the assembly (see Section 2.12.2.2 on p. 735).

Bodies which are built in an assembly and local parts contained in it have no loading types. They are always entirely present in the assembly.

Any changes made in an assembly loading type are regarded as editing the assembly; therefore, when the assembly is being closed, the request for saving the edited file will appear. Select **Yes** to save assembly files and all assembly components, or **No**, if you do not need to save those documents.

2.12.2.1. Component Loading Types

Component load modes are component load methods differing by data amount stored in computer memory: **Full**, **Simplified**, **Empty**, **Dimensions**.

2.12.2.1.1. Full

If the **Full** loading type is selected, the component is loaded in a normal way, i.e. it will be visible in the model Tree or window. The **Full** loading type is not labeled by a special symbol in the Tree.

By default, all created components have the **Full** loading type.

2.12.2.1.2. Simplified

In case of the **Simplified** loading type, a component is loaded so that it is displayed in the Design Tree and Model window. However, in the Model window, the components are displayed without wire frame lines and with less accuracy (i.e. less “smooth”).

A simplified component icon is marked with the “cloud” symbol,

See Section 2.12.2.1.5 on p. 732 for more information about partial loading components.

2.12.2.1.3. Empty

In case of the **Empty** loading type, the component is not loaded. It can only be seen in the Design Tree.

Half-tone gray square is applied on the unloaded component icon,

See Section 2.12.2.1.5 on p. 732 for more information about partial loading components.

2.12.2.1.4. Dimensions

In case of the **Dimensions** loading type, the component is loaded so that it could be seen in the Design Tree, while only its outline box is displayed in the model window. Refer to Section 9.1.11.13 on p. 1737 for more information about the models' dimensions display settings.

The icon of the component with the **Dimensions** loading type is denoted with the “3D box” sign.

See Section 2.12.2.1.5 on p. 732 for more information about partial loading components.

2.12.2.1.5. Peculiarities of partial loading components

Components with partial loading (**Simplified**, **Empty**, **Dimensions** types) have the following differences from the fully loaded components (**Full** type):

- ▼ preview of the component composition is not available (no “+” to the left from such component name),
- ▼ it is impossible to view component's variables (the list of component's variables is not present in the Variables Window),
- ▼ the BOM internal object, corresponding to the component, is not available for editing in assembly.

It is also the unloaded components' (**Empty** type) peculiarity that, if just one such component is a part of a mating, the mating is **blocked**. Such blocked mating cannot be edited or deleted. Such blocked mating is marked by a lock icon in the Design Tree. To remove blocking of the mating, all participating components should be fully loaded.

The partial loading component loads automatically in full when the following actions are performed:

- ▼ any operation is applied to the component (creation of a round hole on the component's surface, rounding of the component's edges and so on), as well as editing of this operation;
- ▼ specifying a component for construction of another object (specifying the component's surface for creation of a sketch or thickening and so on), as well as editing the object;
- ▼ mating for a component, as well as editing the mating;

- ▼ specifying the component as an initial object for an array of components, as well editing the array;
- ▼ movement of a component within an assembly's structure;
- ▼ component shift or rotation.
- ▼ calling the component editing command in the window or in place;
- ▼ changing the component's source file.

Hereafter, the automatically loaded component can be unloaded, simplified or dimensions can be applied to it. However, bear in mind that full loading of a component should be automatically restored when the assembly is re-built. This occurs in the following cases:

- ▼ component is a source object or an instance of an array of components,
- ▼ an operation is applied to the component which results in creation or removal of surfaces and edges (**Chamfer**, **Hole**, **Surface splitting**, **Remove surfaces** and so on).
- ▼ subassembly component is loaded in full if model diversification commands are executed, except for the **Simplified** component loading type when components remain simplified after its diversification or canceling.

2.12.2.1.6. Selection of the component loading type

You can select a loading type for a component at any assembly level.

In order to change loading type of a selected component (part or subassembly), call the **Loading types — Full/Empty/Simplified/Dimensions** command (Fig. 2.12.1) from the context menu or from the **Assembly editing** bar.

You can select a loading type created in the assembly's source file for a subassembly component. To do so, highlight the subassembly component and run the **Loading types — Select...** command from the context menu or click the **Loading type applied** button on the **Current state** bar. For details about assembly loading types see Section 2.12.2.2.3 on p. 739.

Loading type can be changed for several components of the same type, all objects of the *Components* section, all subassembly components, as well as components group or branch. To do so, select components, section, group and so on, and call the command as it is described above.

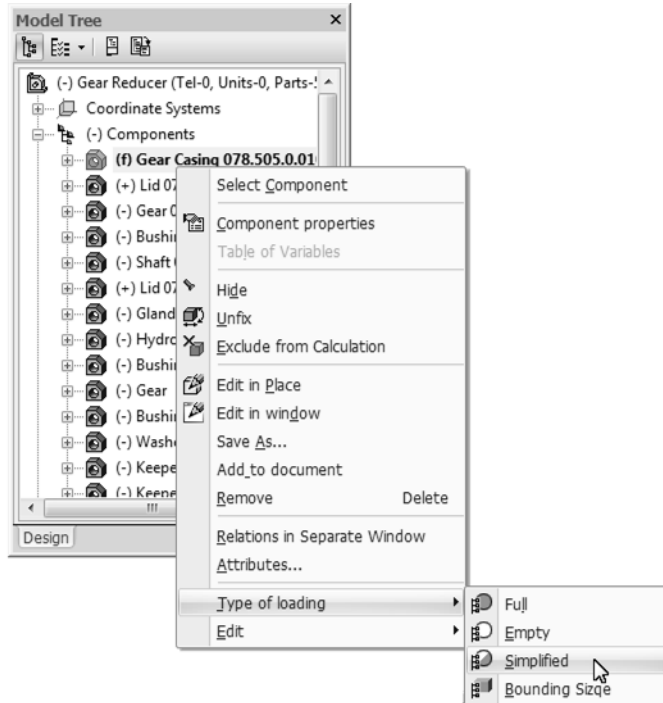

Fig. 2.12.1. Selecting a Component Loading Type

Alternation of a loading type for one array instance should be applied to other instances and initial component.

Changing a loading type of one component insertion (including a standard item) engages all other insertions of the same component in the current assembly.

If loading type is changed, note the following.

- ▼ Loading types with descending detalization — **Full, Simplified, Dimensions, Empty**.
You can change the loading type for components to the **Full** type or to a less detailed type.
For example, components with the **Empty** or **Dimensions** loading type cannot be loaded with the **Simplified** type. In order to do such loading, you should at first load the components in full and then partially.
- ▼ You cannot apply a loading type which is less detailed than that applied in the component file, if the file is opened in a separate window. For example, a part component cannot be unloaded, if its source file is open.
- ▼ You can apply any loading type created in its source file to a subassembly component. If several subassembly components are selected for execution of a command, note the following:
 - ▼ loading types of the first specified subassembly element are available on the Property Bar;

- ▼ loading type is applied to all selected subassembly components which have a loading type with the same name in their files; each subassembly is loaded individually in accordance with the loading created in the process of this loading type creation.

Subassembly components are links to their respective files.

Therefore, if model files are opened, any changes of loading types (for example, creation, editing, or applying) in the subassembly file are transferred to the assembly which contains it. And, vice versa, if a subassembly has a different loading type in assembly, it will also be automatically applied in the subassembly file.

2.12.2.2. Assembly loading types

Assembly loading types are different combinations of assembly components' loading types (see Section 2.12.2.1 on p. 731).

There are **system** and **user** assembly loading types.

Every assembly has system load modes accessible: **Full**, **Empty**, **Simplified**, **Dimensions**. When you select one of them, all assembly components will be loaded in the same mode (Fig. 2.12.2, a).

User loading types are created for an assembly by the user and saved in the assembly file. User types are used to load various components in different ways and/or prohibit their editing (Fig. 2.12.2, b). See Section 2.12.2.3 on p. 739 for information about application of loading types.

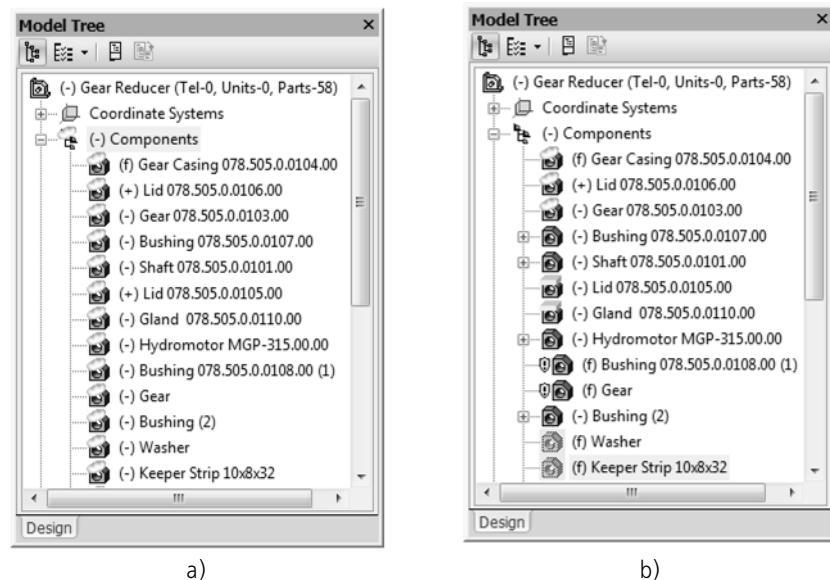

Fig. 2.12.2. Assembly loading type examples: a) simplified system type, b) user type

One of load modes in an assembly is **applied**. By default, this is the *Full* system load mode. The applied assembly loading type is displayed on the **Current state** bar. An asterisk in front of the loading type (Fig. 2.12.3) means that the loading type of one or several components is

different from the one applied (i.e. was changed by the user, see Section 2.12.2.1.6, or automatic change from partial to full loading took place, see Section 2.12.2.1.5 on p. 732).

Fig. 2.12.3. Displaying the applied loading type

Using of simplified loading types allow to free resources of your computer and speed up work with large assembly models. Thus, you can select the **Full** load mode only for the subassembly with which you are working at the moment and the **Empty** load mode for the rest components. If you need to see location of these components in an assembly, they can be loaded in **Simplified** or **Dimensions** mode.

Partial loading of components is preferred to excluding components from calculations, these loading types do not affect hierarchical and associated relations between model objects. Besides that, components with the **Simplified**, **Empty**, and **Dimensions** loading type, in contrast to those excluded from calculations, are transferred to the associative drawing of the model in the same with as those with the **Full** loading type.

Any assembly load mode can be password protected (see Section 2.12.2.3 on p. 741).

2.12.2.2.1. System loading types

System assembly loading type — **Full**, **Empty**, **Simplified** or **Dimensions**. Applying one of these types means that all assembly components have the same loading type. For example, the **Simplified** loading type means that all of its components are downloading with simplification. For details about component loading types see Section 2.12.2.1 on p. 731.

By default, the **Full** loading type is applied to assemblies.

System types cannot be deleted from the model.

2.12.2.2.2. User loading types. Creation and deletion

The custom assembly load mode is a certain combination of load modes of assembly components. Moreover, the custom load mode allows to save information on “read-only” attributes of components.

You may preset several customized loading types for the same assembly. All customized loading types are stored in the assembly file.

Password protection of assembly load modes allows to control access to nodes of a large assembly in case of team work, provided that different custom modes deny access to some components and allow access to others (see Appendix VII).

To switch to managing loading types, call any of the following commands:

- ▼ the **Loading types** command from the assembly's context menu;
- ▼ the **Loading type applied to assembly** command by clicking the same-named button on the **Current state** bar.

Once the command has been called, control elements appear on the Property Bar making it possible to create, edit, delete loading types (Fig. 2.12.4).

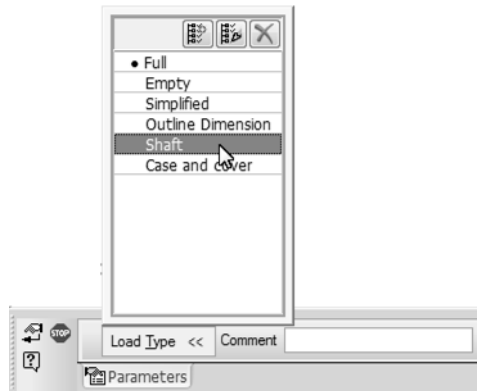

Fig. 2.12.4. Property bar in the process of working with loading types

Assembly loading types are displayed in the **Loading type** list. The applied load mode is marked with a circle or asterisk. The asterisk (*) instead of the marker in the list or in the **Applied loading type** field on the **Current state** bar means that the current set of component loading types differs from the applied set.

Creation of a loading type

To create a customized load mode for the current assembly, complete the following steps.

1. Preset the required loading types for assembly components (see Section 2.12.2.1.6 on p. 733).
2. You can prohibit editing of some components (see Section 2.12.3.1 on p. 744).
3. Call the command for working with the loading types.

Component loading and unloading, applying or removal of the read-only status are possible after calling the command.

4. Click the **Create** button above the **Loading type** list on the Property Bar.

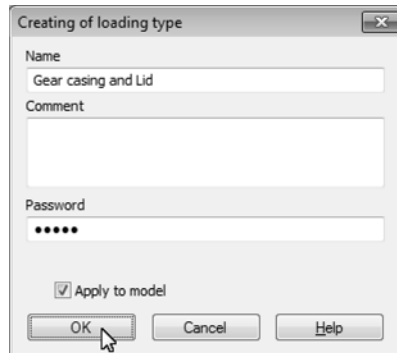

Fig. 2.12.5. Creation of a Loading Type for the Current Assembly

5. Enter the loading type name in the **Name** field of the **Loading type creation dialog**. The name should be different from other loading types names in the current assembly.

Names of the loading types created in subassembly component files can be the same. The same names can be used to simultaneously load subassembly components in an assembly with the loading type required for each of them; the loading type is defined by the settings of the user loading type with the same name.

6. If a created loading type should be protected by a password, enter the password in the **Password** field and confirm it in the appearing dialog.
For more information on password protection of load modes refer to Section 2.12.2.3 on p. 741.
7. In order to apply a new loading to a model, enable the **Apply to model** option. If the option is disabled, the applied loading type will be the same as it was before the creation.
8. Close the dialog by click the **OK** button.
9. In order to apply a different loading type, select it and click the **Apply** button on the Special Control Panel.
10. Click the **Interrupt command** button to leave the command.

Deletion of the loading type

To delete the customized load mode of the current assembly, complete the following steps.

1. Call the command for working with the loading types.
2. In the **load mode** list of the Property Bar select the loading type to be deleted.
3. Click the **Delete object** button above the list.
The selected loading type shall disappear from the list.
When you delete the applied load mode, the preceding in the list load mode becomes current.
4. To leave the command, click the **Interrupt command** button on the Special Control Panel.

A load mode can be password-protected, and several protected load modes can make hierarchical “chains” (see Section 2.12.2.3). Deletion of protected load modes has the following peculiarities:

- ▼ you need to enter a password to delete a load mode that is not current or slave to it (the corresponding dialog will pop up after you click the **Delete** button),
- ▼ you cannot delete the current load mode included into a “chain” but not being the first in it (the **Delete object** button is not available).

2.12.2.2.3. Selecting Assembly Loading Type

You can select the assembly load mode:

- ▼ before opening its file;
- ▼ while working with assembly.

Use the **Load Mode** list to specify the assembly load mode before opening it. This list appears in the file open dialog when you select an assembly file (*.a3d).

The **Loading Type** list contains **Full**, **Empty**, **Simplified**, **Dimensions** loading options, as well as customized options (if any) (Fig. 2.12.6).

Fig. 2.12.6. Selecting a loading type while opening an assembly

Select the required load mode and click button **Open** in the Open File dialog. The assembly shall be opened. The loading type selected during opening will be **applied** to the assembly. It means that all assembly component will be assigned with the **Full**, **Empty**, **Simplified**, **Dimensions** loading type. If a user loading type is selected, each component will have its specific loading type.

In order to apply another assembly loading type while working with it, choose it from the **Loading type applied to assembly** list in the **Current state** bar (Fig. 2.12.7).

Fig. 2.12.7. Loading type selection for the current assembly on the **Current state** bar

Similar to assembly opening stage, this list contains names of the system and user (if any) loading types. You can create and apply a new type if it is missing in the assembly (see Section 2.12.2.2.2 on p. 736).

If a password-protected loading type is selected (see Section 2.12.2.3 on p. 741), the password entry dialog will appear on the screen except for the following cases:

- ▼ when a system loading type changes to another,
- ▼ when the selected load type is marked as applied with a circle or asterisk.
- ▼ when the selected load type is a subordinate one with respect to the applied mode.

Note that when loading an assembly file by specifying its name in the **File** menu, selection of load mode is impossible. An assembly will open with the load mode that was applied at the moment of its saving. The same is true when opening a subassembly of the current assembly with the **Edit in Window** command.

In order to change the subassembly component loading type to a type created in its source file, highlight the component in the Design Tree and click the **Loading type applied to assembly** button on the **Current state** bar. Specify the **Loading type** in the Property Bar and click the **Apply** button on the Special Control Panel.

2.12.2.2.4. Loading types editing

You can change the following during the loading type editing:

- ▼ in the system type — password and comment,
- ▼ in the user type — loading types of one or several components, loading type name, its password and commentary, as well as apply and remove read-only status.

To edit a loading mode of the current assembly, complete the following steps.

1. If you edit the state of a model, change loading of the components (see Section 2.12.2.1.6 on p. 733). If necessary, you can ban or allow editing of some components (see section 2.12.3 on p. 744).
2. Call the command for working with loading types in the same ways as it was done during their creation (see Section 2.12.2.2.2 on p. 736).

Component loading/unloading, applying/removal of the read-only status are possible after calling the command.

3. Specify the edited loading type in the **Loading type** list.
4. Click the **Edit** button above the **Loading type** list on the Property Bar.
5. Enter the password of the edited loading type, if it is password-protected.
6. Change parameters of the loading type in the **Loading type editing** dialog in the same way as it was done during its creation. For more information about password change, refer to Section 2.12.2.3.3 on p. 743.
7. In order to apply a new loading to a model, enable the **Apply to model** option. If the option is disabled, the applied loading type will be the same as it was before the editing. See Section 2.12.2.2.3 on p. 739 for information about application of loading types.

8. To transfer information about the current model's state (loading and read-only status of the model's components) to the edited type, enable the **Update to current model's state**. If the option is disabled, the information is not transferred.
9. Close the dialog by click the **OK** button.
10. To leave the command, click the **Interrupt command** button on the Special Control Panel.

2.12.2.3. Passwords for load modes

You can set passwords for system and custom assembly load modes.

A load mode that has a password is called a **protected load mode**.

Password is requested when you attempt to do the following:

1. opening a protected assembly, opening its subassemblies with protected loading type using the **Edit in window** or **Edit** in place command.
2. application of the password-protected load type.
3. deletion or editing of a protected loading type which is not applied,
4. removing read-only status from the component which was set as a result of protected loading type application (read-only status is indicated by a gray “shield” sign).

If incorrect password is entered, the above-mentioned operations will be blocked.

The password of system load modes can be used instead of the password of any custom load mode.

Password entry dialog is presented in Fig. 2.12.8.

Fig. 2.12.8. **Loading type password** query dialog

Loading type and **Access** fields are available only in case of an assembly opening.

From the **Loading type** list, you can choose another loading type. If a loading type unprotected by password is chosen, the **Password** field will be disabled.

From the **Access** list, you can choose a file opening variant for editing or for reading only.

You can set password on a loading type in the process of its creation or editing in KOMPAS-3D.

Password of the edited or applied loading type is not requested if a system loading type password was entered earlier to remove a component's read-only status (see Section 2.12.3.2 on p. 745).

2.12.2.3.1. Loading type password setting, editing and deletion

An existing password for system loading types is a prerequisite for setting password for the user loading type. In order to set, edit, or remove password, complete the following steps.

1. Call the command for working with loading types in the same ways as it was done during their creation (see Section 2.12.2.2.2 on p. 736).
2. Select the load mode to password-protect in the **Loading type** list on the Property Bar.
3. Click the **Edit** button above the list.
4. In order to set password, enter it in the **Password** of the appearing dialog.
A password may consist of 1 - 38 characters, including spaces.
Confirm password.
In order to change password, replace (*) symbols in the **Password** field with a new combination of symbols.
In order to delete password, remove all symbols from the **Password** field.
5. Close the password entry dialog with the **OK** button.
The protected load mode will be marked with a “key” in the list.

When setting a password for one of the system load modes, the same password will be automatically set for the rest system load modes.

6. If necessary, set a password for other load modes repeating steps 2-5.
7. To leave the command, click the **Interrupt command** button on the Special Control Panel.
8. Save the assembly file.

If the system load modes are protected, you can enter a password for the custom load mode directly in the process of its creation (see Section 2.12.2.2.2 on p. 736). Enter password in the **Password** field.

Password protection of all assembly load modes allows controlling access to nodes of a large assembly in case of the team work provided that different custom modes deny access to some components and allow access to others (see Appendix VII).

As a result of password setting for a user loading type, hierarchic “chains” can form (see Section 2.12.2.3.2).

2.12.2.3.2. Hierarchy of protected load types

Protected load modes can make hierarchical “chains”.

A “chain” forms if another protected load mode was **applied** at the moment of creating a new protected load mode (or at the moment of assigning a password to a custom load mode). In this case, the load mode being created (or protected) becomes **slave** with respect to the applied one, which in its turn, becomes **source** with respect to that being created (or protected). The list of load modes (when you work with the **Loading Types** command) will show the name of the slave load mode indented relative to the name of the source one (Fig. 2.12.9).

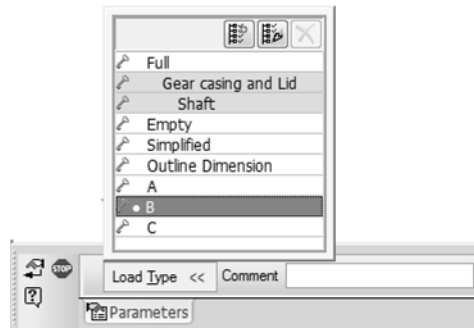

Fig. 2.12.9. Hierarchical “chains” of protected load modes

You can delete a slave load mode or its password only in case the source load mode is applied. Names of load modes that cannot be deleted or for which password cannot be disabled under the applied load mode are displayed in the list of load modes against the gray background (Fig. 2.12.9).

If a custom load mode is subordinate to the system one, it is sufficient to have any system load mode as the current mode to delete it.

If source load mode B with slave load mode C is, in its turn, slave to load mode A, then load mode A is considered source with respect to B and C; B and C are considered slave to A.

2.12.2.3.3. Loading type password editing and removal

For password removal, do what you did to set password for a model's loading type (see Section 2.12.2.3.1 on p. 742) but delete all symbols from the **Password** field in the **Edit loading type** dialog instead of entering symbols.

In order to change password, enter new symbols in the **Password** field and confirm the new password.

Editing and removal of the **applied** assembly loading type's password or any of its subordinate loading types do not require password entry.

When you delete passwords of the system load modes, a request will pop up to delete passwords of custom load modes. You can confirm or reject the deletion.

2.12.3. Component's read-only status

By default, all assembly's components can be edited. However, if necessary, you can set read-only status to a component.

The read-only status means that only a limited number of operations is available. For example, the component cannot be edited, moved, exploded; you cannot change its loading type and so on (see Section 2.12.3.3 on p. 746 for specific features of such components).

You can prohibit editing:

- ▼ “manually” for each component separately using special commands (see Section 2.12.3.1);
- ▼ by application of a loading type containing information about the read-only status (for information about loading type selection, refer to Section 2.12.2.2.3 on p. 739).

When working with an assembly, you can apply or remove the read-only status to components without limitations. Information about read-only status of components is not saved in system loading types.

The model's state taking account of components' read-only status can be saved in the user loading type only in the process of its creation or update (see Section 2.12.2.2.4 on p. 740).

Components added to an assembly after application of a password-protected loading type will automatically have the read-only status in other loading types.

2.12.3.1. Read-only status setting

You can apply or remove read-only status to/from one or several components on any nesting level of an assembly.

In order to apply or remove the read-only status for a component (or components), call the following command:

- ▼ **Editing — Prohibit** and **Editing — Allow** commands from their context menus (Fig. 2.12.10, a);
- ▼ **Read-only status for selected components** by clicking the same-named button on the **Assembly editing** bar.

After you call the **Editing — Read-Only** command, the component is assigned 'read-only' attribute and is marked with a “shield” in the Design Tree (Fig.2.12.10, b). For more details about using these components, see Section 2.12.3.3 on p. 746.

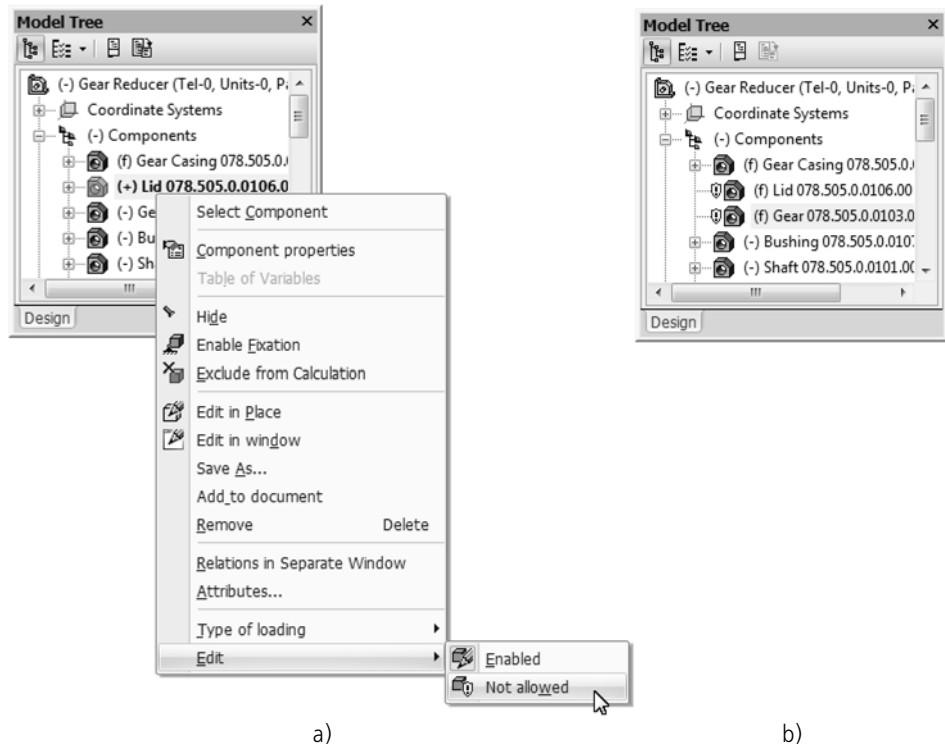

Fig. 2.12.10. Read-only status of a component a) setting, b) display in the Design Tree

In order to remove the read-only status from the selected component(s), the following command should be called from its context menu: **Editing — Allowed** or click the **Read-only status for selected components** on the **Assembly editing** bar. The “shield” next to the component in the Design Tree disappears.

You can create a new loading type by setting the read-only status or edit an existing loading type. For more information about saving the read-only status, refer to Section 2.12.3.2 on p. 745.

2.12.3.2. Saving read-only status for components

Information about the component's read-only status can be saved in the user assembly loading type. It is saved at the moment of an existing loading type creation or update. For more information about loading type creation, refer to Section 2.12.2.2.2 on p. 736; see section 2.12.2.2.4 on p. 740 for more details about editing.

The component's read-only status will not be saved in the assembly unless it is saved in the loading type.

After application of the selected loading type with information about the read-only status of its components, the respective indications will appear in the Design Tree.

- ▼ blue “shield” signs — if loading type is applied which is not password-protected,

- ▼ gray “shield” signs — if a password-protected loading type is applied (see Section 2.12.2.3 on p. 741 for password setting).

The user can remove the read-only status from the selected component using the **Editing — Allowed** command, for example (see Section 2.12.3.1 on p. 744). If a component is marked with the gray “shield” sign, you will have to enter the system loading type password to remove the read-only status.

Removal of the loading type password **does not remove read-only status** from components automatically — the “shield” sign will remain gray.

In order to allow editing of such a component, call the **Editing — Allowed** command after password removal.

In order to save the read-only status in a loading type created earlier, perform the following operations:

1. Apply the loading type to which the read-only status should be assigned. For example, choose it from the **Loading type applied to assembly** list on the **Current state** bar (see Section 2.12.2.2.3 on p. 739).
2. Apply the read-only status to components in the model.
3. Call the command for working with the loading types (see Section 2.12.2.2.2 on p. 736).

Applying/removal of the read-only status is possible after calling the command.

4. Call the **Edit** command by clicking the button above the list. Enable the **Update to current model's state** option in the dialog. Close the dialog by click the **OK** button.
5. Save the assembly.

It is impossible to assign the read-only status to the system loading type. You can create a user type and apply the read-only status during system loading.

So, using protected load modes you can control access of different users to various assembly components during team work.

2.12.3.3. Specifics of working with read-only components

This section lists restrictions imposed on working with read-only assembly components.

2.12.3.3.1. General specifics

If a component has the read-only status, you cannot do the following when working with it:

- ▼ delete it from an assembly in any way,
- ▼ edit it in a window or in the assembly context,
- ▼ control inclusion in calculation,

- ▼ edit properties,
- ▼ explode it (if a component is a subassembly),
- ▼ move and rotate it,
- ▼ change a load mode.

2.12.3.3.2. Working in the model construction tree

If a component is read-only, the following restrictions apply when you work with it in the Design Tree.

- ▼ The commands of the context menu that cannot be executed are inaccessible.
After you call the **Properties** command, the Property Bar will have the **MP Parameters** and **Source File** tabs only. Tab controls are inaccessible.
- ▼ A component will not be included into a new subassembly obtained by merging selected components.
- ▼ You cannot view component composition.
- ▼ You cannot edit component name.
- ▼ Other components cannot be copied or transferred to a read-only subassembly.

2.12.3.3.3. Performing operations and building objects

- ▼ If a component is read-only, you cannot apply to it the operations that result in creation or deletion of faces and edges (**Chamfer**, **Hole**, **Array**, **Surface Splitting**, **Delete Faces**, etc).
If a component is provided with the “read-only” attribute in the result of some operation applied to it, this operation will be **blocked**. You cannot do the following if the operation is blocked:
 - ▼ edit,
 - ▼ directly change variable values (variables can be only assigned values by link or in the result of calculation of expressions),
 - ▼ delete,
 - ▼ control inclusion in calculation,
 - ▼ use as a source array element.

Blocked operations are marked with a “lock” icon in the Design Tree (Fig. 2.12.11). Blocked operations remain effective for read-only components.

After you disable the “read-only” attribute of the component, the operation applied to it will be unblocked.

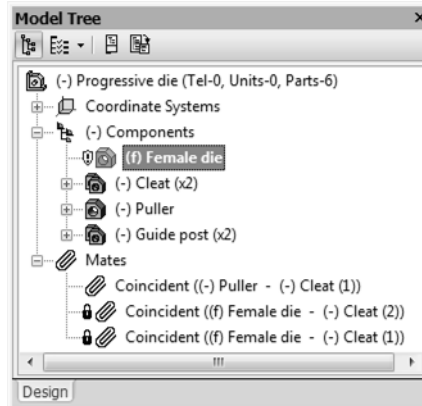

Fig. 2.12.11. Model objects blocked in the result of applying the read-only status to one of the components

- ▼ The commands not supposed to change faces and edges can use read-only components. For instance, a part face can be a draft base in the **Draft** command or the source surface in the **Thicken** command.

In addition, the objects belonging to a read-only component can be sources for new objects. For instance, a part face can be used to create a sketch or to place a symbol; points created in a component can be used to build auxiliary axes, planes, etc.

You can use a read-only component to build other objects if this component has the **Full** load mode.

2.12.3.3.4. Arrays of components and insertions from one source

- ▼ It is impossible to create an array of read-only components.
- ▼ If at least one of the source components of the created array is assigned the “read-only” attribute, this array and its instances will be **blocked** (similar to the operation applied to a read-only component, see above).
- ▼ The component copies, obtained both by array creation and by repeated insertion, make a group in the Design Tree. In the first case, all group components will be automatically assigned or unassigned the “read-only” attribute once it is assigned or unassigned to one of the group components. In the second case, the “read-only” attribute must be assigned or unassigned to each group component individually.

Change in a load mode for one component applies to all its insertions irrespective of whether they are readable or editable.

2.12.3.3.5. Mates

- ▼ A read-only component cannot be involved in mates.

- ▼ If at least one of the components involved in the created mate is assigned the “read-only” attribute, this mate will be **blocked** (similar to the operation applied to a read-only component, see above).
A blocked mate will not work.
- ▼ When you delete the assembly component with which a read-only component is mated, the blocked mate will be also deleted. After removal of this attribute or after you re-open the assembly, the component location will be recalculated in compliance with the rest mates.

When you delete an object used to mate (e.g. edges), the blocked mate will not be deleted but will be marked as failed.

2.12.3.3.6. Variables

- ▼ You cannot directly change variable values of a read-only component.
- ▼ Variables of a read-only component can be assigned values by link or in the result of calculation of expressions they are involved in.

2.12.3.3.7. BOM items

- ▼ You cannot edit a BOM item of a read-only component.
- ▼ Changes in a BOM item of a read-only component are transferred to an assembly after you remove this attribute from the component or after you re-open the assembly.

2.12.3.3.8. Rebuilding

- ▼ If the source file of a read-only component has been edited, it will be rebuilt automatically upon opening an assembly, without a request to rebuild.
- ▼ A read-only component is rebuilt in the ordinary way after you change its source objects or variable values by clicking the **Rebuild** button.

2.12.3.3.9. Model variants

The read-only status of the component is transferred from the source one to dependent ones, i.e. if a source variant component has the read-only status, editing of the respective component of the dependent variant will also be impossible. The “lock” sign next to the component's symbol in the Design Tree of the dependent version will be replaced by the “shield” sign.

It is impossible to cancel the link between such component and the source variant component, since the **Cancel link** command of the component's context menu in the Tree of Variants will be unavailable.

2.13. Model versions

2.13.1. General Information about Versions

2.13.1.1. Basic concepts

A model document can contain data about several model construction versions with common constructive attributes but having some differences. These variants are called **model versions** (hereafter — versions).

All model versions are contained in a single **group** document as individual models.

The **main** version is created by default during creation of the model. This version is the source variant of the model and is used for creation of other versions of the model.

You can create a version directly in the main version or use another version previously created on the basis of the main one. The version that is used for creation of other version is the **source** one.

The system supports creating **dependent** and **independent** versions. The dependent version is linked to the source version, while the independent one has no such link. Presence of such link is defined during creation of the version and cannot be changed later, i.e. it is impossible to make a dependent version independent and vice versa.

Objects of an independent version may be edited or deleted individually. They are not affected by changes in the respective objects of the source version.

Objects of a dependent version are linked to the respective objects of the source version. Changing or deleting objects of the source version is reflected in the dependent one.

A set of document's versions has a graphical representation in the form of **Tree of Versions** which is displayed in a separate tab of the **Model Tree** window. You can work with any version of the model after making it **active**. The models will be displayed as objects of the current version in the model window and in the model's Design Tree.

There are **permanent** and **variable** data in a model's version. Permanent data is identical for all model versions contained in a single document. Variable data differs for various versions.

2.13.1.2. Tree of Versions

The tree of the model's versions is displayed in the **Versions** tab of the **Model Tree** window (Fig. 2.13.1).

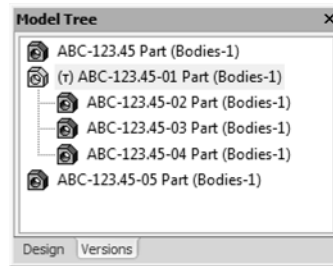

Fig. 2.13.1. Tree of model's versions

In the first position within the tree, there is the main version of the model; other versions, both dependent and independent, are displayed in other positions. All independent positions are located on the first level of the tree's hierarchy. Dependent versions are subordinate to the version which is the source version for them.

If necessary, you can hide dependent versions by double-clicking the icon of their source version. Double-clicking it again will display hidden versions.

Each version in the Tree of Versions has a name and an icon.

The name consists of a designation and a version's name. The designation is formed during creation of a version (see Section 2.13.2.2 on p. 757). The default name is the same as the name of the main version. Both designation and the name can be changed (see Section 2.13.3.4 on p. 763).

Note that, depending on the settings (see Section 9.2.7.4.13 on p. 1857), the version's name may contain a designation and a name or a name only. In the latter case, designation of the version is saved in the system but it is not displayed in the Tree of Versions.

Versions' icons are displayed in the Tree of Versions in blue color. If a version is the current one, its icon is yellow.

If a version is the dependent one, its objects are linked to the respective objects of the source version. A linked object in the Design tree is marked by the "lock" sign. It means that the object cannot be edited or deleted individually.

If necessary, you can create an additional window of the Design Tree for any version. For this purpose, choose the required version in the Tree of Versions and call the **Version in additional window** command in its context menu.

The additional window displays a copy of the Design Tree for the selected version. The header of the Tree's additional window contains the name of the version. Working with the additional window of the Design Tree is the same as that described in Section 2.1.2.4 on p. 109.

2.13.1.3. Versions in the Document Manager

In order to create a set of a model's versions, you can use the Document Manager (Fig. 2.13.2). You can use it to perform the following actions:

- ▼ create and delete model's versions, change their position in the list of versions,

- ▼ view properties of versions and change their values,
- ▼ set different values of variables for different versions,
- ▼ save data related to versions in files of different formats and use the saved data in order to create a set of versions in other models.

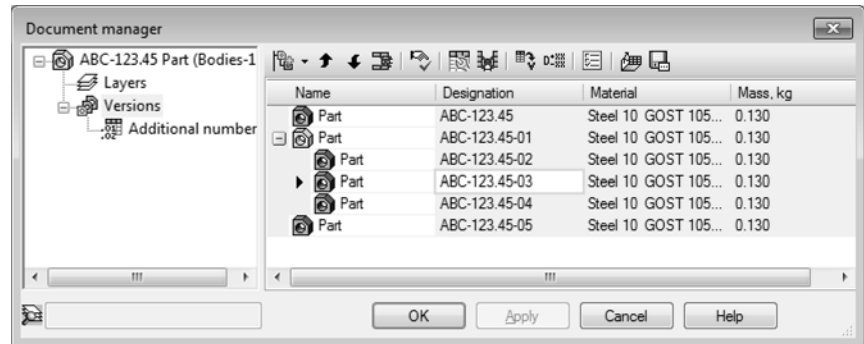

Fig. 2.13.2. Document Manager

The **Document Manager** dialog appears on the screen after calling the **Manage Versions...** command using one of the following methods:

- ▼ from the **Editor** menu,
- ▼ by clicking the button of the same name on the **Current status** bar,
- ▼ from the context menu of the version in the Tree of Versions,
- ▼ from the **Current Version** submenu of the root object's context menu in the Design Tree.

The first part of the dialog displays the document's Element Tree. If the dialog is called by the above-mentioned commands, the **Versions** element will be active in the Tree. The right section of the dialog displays the list of the model's versions created in the document and a toolbar for various operations with respect to versions.

The list of versions is displayed in the dialog as a table. Each column of the table corresponds to a certain property of the model.

You can create a set and specify order of properties in the table. For this purpose, click the **Customize Columns** button on the dialog's toolbar. The **Customize Columns** dialog will appear on the screen (working with the dialog is described in Section 5.1.4.2.2 on p. 1391).

Customization of columns with variables has certain peculiarities described in Section 2.13.3.5.2 on p. 766.

If necessary, you can disable display of any column, except for the **Name** column, without calling the customization dialog. For this purpose, activate the cell of the required column and click the **Delete Column** button.

In the Manager, you can add and remove a model's versions, change their position in a set of the document's versions, specify various values of properties for different versions, save information about versions and use this information for creation of a set of versions in other documents.

The **Document Manager** dialog makes it possible to work not only with model's versions but also with additional version numbers.

In order to perform different operation with respect to additional numbers, enable the **Additional Numbers** element in the dialog's tree. In the right section of the dialog, the list of additional numbers, created for a model with versions, will be displayed together with the toolbar for various operations to be performed with respect to additional numbers.

The list of additional numbers is displayed in the dialog as a table. Setup of the table's columns is the same as the setup of versions (see above).

In the Manager, you can add and delete additional numbers, change their position in the list, modify additional numbers and commentaries assigned to them, save information about the additional numbers and use this information for creation of additional numbers in other documents. Working with additional number is described in Section 2.13.3.6 on p. 770.

After performing all necessary operations in the dialog, close it by clicking the **OK** button. All changes will be saved. The **Cancel** button closes the dialog and without changes saving.

If you need to save changes without closing the dialog, click the **Apply** button.

Operations of adding, moving, and deleting variants will be saved automatically. It will not be possible to undo them in the Manager.

2.13.1.4. General procedure for working with versions

While working with versions, you are recommended to proceed as follows.

1. Create a new model. This model will be the main versions.
2. Specify a base designation and name of the main version (see Section 2.13.2.1 on p. 755). Each version created in the model will be assigned this designation and name.

Numbers of versions, created in the model are formed automatically in accordance with the settings. If default number forming parameters do not comply with the requirements adopted at your enterprise, change them prior to creating any versions. Setup of version numbers forming is described in Section 9.2.7.4.3 on p. 1845.

3. Create all objects and variables in the main version that should be transferred to other versions of the model.
4. Create the required versions of the model (see Section 2.13.2.2 on p. 757).

If necessary, you can change properties of the created version (see Section 2.13.3.4 on p. 763) or its position in the list of versions (see Section 2.13.2.3 on p. 760).

5. Edit versions' objects that should differ from the main version's objects. If necessary, you can create new objects in versions and delete the existing ones. Working with objects of dependent and independent versions is different (see Section 2.13.3.2 on p. 761).

Note that the model window and the model's Design Tree display objects of the version which is being current (active) at the moment. In order to edit a version, make it the current one (see

Section 2.13.3.1 on p. 761).

Changes made in the source version are transferred to dependent versions with some peculiarities described in Section 2.13.3.3 on p. 762.

6. Use variables to modify the geometry of dependent versions (see Section 2.13.3.5 on p. 765).
7. Edit the values of versions' properties that should differ from the values of the main version's properties (see Section 2.13.3.4 on p. 763).

You can insert the required model's version into another document (for example, into an assembly as a component), add an associative view to the drawing with geometry corresponding to the model's version, create a BOM for a model with versions, or create a table of the model's versions in a graphic or text document.

The sequence of creating versions and the order of their placement on the Versions Tree may be arbitrary. This does not affect their order of being listed in the BOM or table of versions.

2.13.1.5. Setup of versions

The following settings related to versions of a model are available in KOMPAS-3D:

- ▼ setup of creation of objects and variables in dependent versions (see Section 9.1.11.10 on p. 1735),
- ▼ setup of new version number forming in a new or current document (see Section 9.2.7.4.3 on p. 1845),
- ▼ setup of a BOM for an assembly with versions in a new document (see Section 9.2.5.2 on p. 1758).

2.13.2. Creation of versions

2.13.2.1. Designation and name of a version

The name of each model's version contains a designation and a name.

Designation of a version consists of a base designation and the version's number.

The base designation is common for all model's versions. The version number is formed individually for each version and has to be unique within the document.

The base designation is set manually. Version numbers are formed automatically but, if necessary, they can also be specified manually.

The number setting option (automatically or manually), as well as numbers' parameters that are formed automatically are defined during the setup process (see Section 9.2.7.4.3 on p. 1845). This setting is taken account of only when creating new versions and does not affect designations of versions that already exist in the model.

A version's designation can be specified:

- ▼ when working with the list of the version's properties in the Property bar (see Section 5.1.4.1.1 on p. 1385); this list is called by the **Version's Properties** command in the context menu of the Tree of Versions or the **Model Properties** command in the context menu of the root object in the Design Tree.
- ▼ when creating a new designation in the Tree of Versions (see Section 2.13.2.2.1 on p. 757),
- ▼ when working in the Document Manager (see Section 2.13.1.3 on p. 752) or in the Property Editor (see Section 5.1.4.2 on p. 1389).

In order to create a designation, a special dialog is used. In this dialog, you can specify the base designation and the version's number. Working with the dialog is described in Section 2.13.2.1.1 on p. 756.

The version's name can be specified when working with the list of version properties in the Property bar, Property Editor or in the Document Manager. The name's text is entered in the field of the respective property.

Later, it will be possible to edit designations and names of versions. The editing process is the same as the process of creation described above.

Methods of editing the versions' properties are described in Section 2.13.3.4 on p. 763; peculiarities of transferring the version's designation and name to other versions are described in Section 2.13.3.4.1 on p. 764.

2.13.2.1.1. Dialog for setting a version's designation

Designation of a version is specified in the **Designation** dialog (Fig. 2.13.3).

Fig. 2.13.3. **Designation** dialog

The **Base designation** field makes it possible to set the base designation of the version. Changes made in this field are transferred to designations of other versions of the model (for peculiarities of transfer of the changes, see Section 2.13.3.4.1).

In order to specify the version number, use the **Version number** field. Changing the number affects the current designation only.

The dialog also allows to change the default separator which is inserted between the designation's parts. As the separator, you can enter any symbol. This symbol will be used only in the current designation.

If the separator contained in a field is removed, and the field remains empty, the deleted separator will be restored in the designation once working in the dialog is finished.

Click the **OK** button to close the dialog. The **Cancel** button closes the dialog and without changes saving.

2.13.2.2. Method of version creation

You can create dependent and independent versions of a model using the Versions Tree or the Document Manager.

Using the Tree of Versions is preferred for creation of individual versions. It is recommended to use the Document Manager for creating a set of several versions.

The contents and the order of versions' positioning in the Manager is absolutely the same as in the Tree of Versions. When adding a version in the Manager, it will automatically added in the respective position of the Tree of Versions.

By default, the model document contains only one version – the main one. It is the source version for the first version to be created. Later, you can use not only the main version for creation of versions but also the versions created by the user.

When creating a version, its name and base designation are inherited from the source designation.

Specify the base value and the name of the main version prior to creation of all other model's versions (see Section 2.13.2.1).

The version number is formed automatically in accordance with the settings (see Section 9.2.7.4.3 on p. 1845) and is added to the version's designation.

If, during the setup process, you disable automatic generation of versions' numbers, the following peculiarities should be taken into account.

When creating a dependent version, its default name will be the same as the number of the source version. When creating an independent version, no default number will be generated. If you need the version's number to be unique within the document, in the first case, change the default number, and in the second case, specify the preferred number of the version.

On the basis of each model's version, you can create a dependent or independent version.

The created version, both dependent or independent, will inherit the geometry, layout elements, the set of variables and property values (including the color and optical properties) of the source version.

Objects that had been excluded from the calculation will be inherited with the *Excluded from calculation* attribute.

Procedure of creation of a version when working with the Tree of Versions can be found in Section 2.13.2.2.1, working in the Document Manager is described in Section 2.13.2.2.2.

2.13.2.2.1. Creation of a version in the Tree of Versions

1. Open the model's Versions Tree.
2. Specify the version which will be the source one for the version being created and call the **Create Version** command from its context menu. Control elements will appear on the Properties

Bar (Fig. 2.13.4).

Fig. 2.13.4. Elements of creating a version

3. In the **Designation** field, the version's default designation is displayed. It consists of the base designation and the version's number.

You can modify any part of the created version's designation using a special dialog (see Section 2.13.2.1.1 on p. 756). In order to call the dialog, click the **Designation** field.

Note the following specifics when editing a designation:

- ▼ changing the base designation will be reflected in other versions of the model (see Section 2.13.3.4 on p. 763),
- ▼ the version's number has to be unique within the document; if numbers of the version being created and of a version that exists in the document are the same, the new version will not be created.

You can select a designation of the version from an external reference (Classifier of the Unified system for design documentation). To do that, click the **Select from Reference** button. The reference must be connected to KOMPAS-3D.

4. Check status of the **Dependent version** option. In order to create a dependent version, the option should be enabled; if you need to create an independent version, the option should be disabled.
5. If necessary, enter commentaries to the version being created in the **Commentary** field.
6. In the **Properties** tab, you can specify the color and optical properties of the version being created.

7. In order to finish creating the version, click the **Create Object** button. The new version will appear in the Tree. It will automatically be the current one.
8. In the same way, create all model's versions you need.

You can also create a version using the Design Tree of the current version. For this purpose, call the **Versions — Create Version** command from context menu of the Tree's root element. Further steps are the same as those described above.

2.13.2.2.2. Creation of a version in the Document Manager

1. Open the Document Manager (see Section 2.13.1.3 on p. 752). The **Versions** element will be enabled in the Manager's tree.
2. Choose the version, that should become the source one for the version being created, in the list of versions in the right part of the Manager's window.

3. In order to create a dependent version, click the **Create dependent version** button in the Manager's toolbar.

If you need to create an independent version, call the **Create independent version** command from the menu of the **Create dependent version** button.

The new version will appear in the list of version of the Manager and in the Tree of Versions. Properties of thee version, including its name and designation, will be displayed in the Document Manager.

If necessary, you can change the designation, name, or any other property of the version (see Section 2.13.3.4 on p. 763). You can also change the version's position in the list of versions (see Section 2.13.2.3 on p. 760).

4. In the same way, create all model's versions you need.

In order to create the list of versions, you can use the list of versions of a different model (see Section 2.13.2.2.3 on p. 759).

5. Click the **OK** button to close the Document Manager.

2.13.2.2.3. Using the list of versions of a different model

The set of versions of an existing model can be used for creating a similar set of versions in a different model. For this, do the following.

1. Open the Document Manager in an existing model with versions (see Section 2.13.1.3 on p. 752).

2. Click the **Save as...** button on the Manager's toolbar.
3. In the appearing file save dialog, specify the folder for saving, choose the **ODF Electronic Tables (*.ods)** or the **Microsoft Excel Electronic Tables (*.xls)** file type and click **Save**.

Information about the model's versions will be saved in the file of the specified type.

4. Open the model in which a version should be created.

5. Open the Document manager.

6. Click the **Read from file** button on the Manager's toolbar.
7. In the appearing file open dialog, choose file of the *ods* or *xls* format and click the **Open** button. The list of variants will be transferred to the model from the file.

Transferred versions will be added to versions existing in the model and positioned after them in the list in the Document Manager or in the Tree of Versions.

You can add versions from several files to the model.

Further operations with added versions is the same as working with the versions created in the model.

When creating a set of versions using the above method, not the following peculiarities.

- ▼ The base designation of versions added from file will not be transferred to versions that already exist in the model.
- ▼ All versions contained in the selected file are added to the model irrespective of whether the model has versions with the same numbers. Numbers of added versions do not change.

- ▼ Only the values of those versions' properties are transferred to the model that are not linked to the model's geometry. Geometry and its related properties, such as mass, properties created from variables of operations' parameters, and so on, cannot be transferred this way.

2.13.2.3. Changing a version's position in the list of versions

When working in the Document Manager, you can change a version's position in the model's list of versions.

For this purpose, choose the version you want to move and click **Move line up** or **Move line down**. The version will be moved, respectively, one position up or down in the list of versions in the Manager or in the Tree of Versions.

Availability of buttons depends on whether it is possible to move a version to a certain position. Versions can be moved within one level of the list.

Changing the version's position in the list does not change its number.

2.13.2.4. Removal of a version

You can remove a version in the following way:

- ▼ in the Tree of Versions, using the **Remove** command which is called from the **Editor** menu or from the version's context menu,

- ▼ in the Document Manager, by clicking the **Delete line** button in the Manager's toolbar.

You can delete any version, except for the main one.

If the deleted version has dependent versions, these versions will also be deleted.

If a dependent version, being the current one, is removed, the current status will be assigned to its source version. If an independent version is the current one, the main model's version will become the current one after its removal.

If necessary, you can delete several versions at once selecting them with the *<Shift>* or *<Ctrl>* keys.

2.13.3. Working with versions

In order to edit objects in a model with versions, the same methods are used as for models without versions.

Changes are made in the current version of the model. If the version has dependent versions, the new changes will be reflected in those versions. If the version is dependent, its objects will be linked to objects of the source version and will not be available for editing. If necessary, you can cancel links between objects and make the changes you need. For more information about version editing, see Section 2.13.3.2 on p. 761.

Parameters of versions' objects can be changed using variables. For more details about peculiarities of working with variables in versions, see Section 2.13.3.5 on p. 765.

A version created in a model can be used in other documents; for example, you can insert it in an assembly as a component or use it for creation of an associative view in a drawing. The required version is selected when operation is being performed. For example, when inserting a component into an assembly, version is selected from the drop-down list in the file open dialog.

2.13.3.1. Choosing the current version

Immediately after creation of a version in the Tree of Versions, it will become the current one. In order to manually make a version the current one, use one of the following methods:

- ▼ in the Tree of Versions, call the **Current** command from the context menu or click the version's name,
- ▼ in the Design Tree, call the **Current version** command from the context menu of the Tree's root element and specify the required version in the appearing list.
-  ▼ in the Document Manager, click the **Make current** button on the Manager's toolbar or call the **Current** command from the version's context menu,
- ▼ on the **Current status** panel (if it is positioned horizontally) — select the desired version from the list in the **Version management** field or type the version's designation in the field.

When opening a model with versions, you can specify the version to be the current one. For this purpose, choose the model's version you need in the **Version** drop-down list.

Objects of the current version are displayed in the model window and in the model's Design Tree.

2.13.3.2. Creation, editing and removal of a version's objects

A version created in a model inherits geometry from the source version. Later on, you will be able to change the version's geometry by adding, editing or removing its objects.

In order to display all objects in the model window or in the model's Design Tree, make the version the current one, as it is described in Section 2.13.3.1.

For convenient handling of a version, you can create an additional Design Tree for it. For this purpose, choose the required version in the Tree of Versions and call the **Version in additional window** command in its context menu.

An independent version is fully autonomous. It is not affected by changes in other model's versions.

Changes made in the source version are reflected in the dependent version.

Objects can be created in any version, both dependent or independent.

If a version, in which an object is created, has dependent versions, the identical object can be created in those versions. The object will be created, if the **Create object in dependent versions** option is enabled in the version setup dialog (see Section 9.1.11.10 on p. 1735). This option also controls adding components to dependent components' versions that are identical to those added to the source version.

Editing and removal of versions' objects have the following specifics.

Objects are available for changing and removal in independent versions.

In dependent versions, individual editing or removal of objects is not available (such objects are marked with the “lock” sign in the Design Tree).

If you need to change or remove an object of a dependent version, cancel its link to the object of the source version. For this purpose, call the **Cancel link** command from the object's context menu. The object will become available for editing and removal, and the **Restore link** command will appear in the context menu. This command makes it possible to restore the link between objects.

Once the link is restored, and the model is rebuilt, the dependent version's object becomes identical to the existing object of the source version. Changes made to the object of the dependent version prior to restoring the link will not be preserved.

Editing and removal of the source version's objects are reflected in dependent versions if the respective objects of dependent versions retain the link to objects of the source version.

In order to transfer changes of objects, rebuild the model with versions by calling the **View — Rebuild** command. Once the command is called, all versions for which rebuilding is required (marked with the red checkmark in the Tree of Versions) will be rebuilt. Deletion of objects is automatically transferred.

If necessary, you can change objects of the model's versions using variables. These operations are described in Section 2.13.3.5.

2.13.3.3. Transfer of objects to versions

Objects that are present in the current version of a model can be transferred to other versions, both dependent and independent. In order to transfer objects, do the following.

1. Make the version, whose objects should be transferred, the current one (see Section 2.13.3.1 on p. 761).
2. Call the **Editor — Transfer to versions** command. Control elements for joining curves will appear on the Properties Bar (Fig.2.13.5).

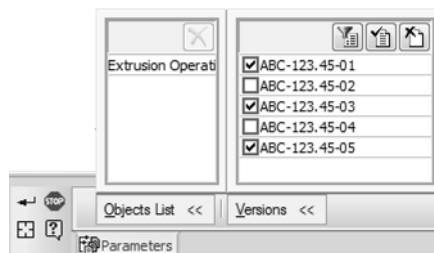

Fig. 2.13.5. Property bar elements

3. Create the list of the current version's objects that should be transferred.

In order to add the required objects to the list, select them by the mouse in the Design Tree or in the model window. The names of the selected objects will appear in the **List of Objects** toolbar.

If necessary, you can delete an object from the list of transferred objects by selecting it in the **List of Objects** bar and clicking the **Delete from list** button.

4. Customize the list of versions to which the selected objects should be transferred. For this purpose, use the **Versions** bar.

By default, this bar displays all versions that exist in the model. If you want the list to contain only dependent versions of the current version (versions that are subordinate to the current version in the Tree of Versions), click the **Only dependent versions** button.

The enabled option is displayed in the left of each version in the list. It means that the selected objects will be transferred to all listed versions. If you do not need to transfer objects to a version, disable its respective option.

In order to enable and disable all options in the list, you can use **Enable all** and **Disable all** buttons.

5. In order to transfer objects, click the **Create Object** button.

If the object being transferred has source objects, such as sketches, the objects will also be passed to the selected versions.

If the object being transferred is already present in the selected versions, this object will not be passed to these versions.

2.13.3.4. Editing properties of a version

A set of a model's properties is the same for all versions contained in it. Working with the set of properties is the same in models with and without versions (see Section 5.1 on p. 1369).

A peculiarity of models with versions is that the common set of the model's properties can be edited when working with any of its versions.

Property values may vary for different versions of the model.

When a new version is created, all values of the source version's properties are transferred to it. The only exception is the *Designation* property. Only part of the version's designation (the base designation) is transferred to the new version. The version's number is formed by the system or is set by the user.

Values of the version's properties can be edited when working with the list of the version's properties in the Property bar.

In the Tree of Versions, the list of properties is called for each of the model's versions by the **Version's properties** context menu command.

In the Design Tree, the list of properties is called for the current model's version. For this purpose, call the **Model properties** command from the context menu of the Tree's root object.

You can change values of properties for a version in the same way as for a model. The general procedure of handling the list of properties can be found in Section 5.1.4.1 on p. 1385.

Besides that, property values of the current version can be edited in the Property Editor (see Sections 5.1.4.2 on p. 1389 and 5.1.4.4 on p. 1395).

If you need to change values of properties for several versions, use the Document Manager (see Section 2.13.1.3 on p. 752). You can customize displaying of columns with all the required properties and specify values of different versions' properties.

Values of properties in the Document Manager are changed in the cells of these properties. The following properties are exceptions to the rule:

- ▼ *Material, Density, Mass* – these properties are edited in the **Mass center characteristics** dialog (see Section 5.1.4.4.2 on p. 1395),
- ▼ *Position, BOM section* – these properties are edited in the **Choose section** dialog (see Section 6.2.2.3.1 on p. 1472),
- ▼ *Designation* – this property is edited in the **Designation** dialog (see Section 2.13.2.1.1),
- ▼ *Substitute material and Coating* — the values of the properties are selected from an external reference file (the file must be connected to the system KOMPAS-3D).

Dialogs for property editing are called by double-clicking the cell of the respective property or by clicking the ellipsis button in the right section of the cell.

Changes of properties made for one of the versions are transmitted to the other versions. This process has some peculiarities described in Section 2.13.3.4.1 on p. 764.

The Document Manager can contain properties created from variables. Peculiarities of editing these properties are described in Sections 2.13.3.5.2 on p. 766 and 2.13.3.5.3 on p. 767.

A version's name, aside from the above-mentioned methods, can also be modified in the Tree of Versions (see Section 2.1.2.5 on p. 111).

2.13.3.4.1. Some peculiarities of exchanging changed properties between versions

When editing version properties, note the following peculiarities in transmitting changes to other versions.

- ▼ The way base designation and name changes are transmitted depends on what version these changes have been made to. The following scenarios are possible:
 - ▼ for the main version, changes are transmitted to the all model versions that have the same base designations/names as the main one,
 - ▼ for a dependent version, changes are transmitted to its initial version and dependent ones if such are available (i.e. all the versions located on the same branch of the Versions Tree as the version being changed),
 - ▼ for an independent version, changes are transmitted to its dependent versions, if any.

Changes in the number contained in the version's designation are taken account of in case of automatic generation of numbers; the number of the newly created version will be next after the greatest number in the list of versions.

- ▼ For properties *Material, Density, Mass* (in case mass is entered manually), *Substitute material, Coating, Developed by, Checked by, Approved by, T. contr., N. contr.*, and the properties cre-

ated from variables, — version property changes are transmitted to the dependent versions that have the same values of respective properties.

- ▼ For the properties *Author* and *Organization* — version property changes are transmitted to all model versions.
- ▼ Changes in other properties of the versions are not transmitted to other versions.

2.13.3.5. Using variables in a version

In some cases, you may need to modify objects of dependent versions retaining their links to objects of source versions. For this purpose, variables are used.

Each geometric object of a model has a set of variables. These include variables of operations' parameters and variables of sketches' dimensions. These variables are used for model geometry handling.

From now on, we mean that variables of sketches' dimensions that are used for handling the geometry, correspond to controlling dimensions (see Sections 2.9.2.1 on p. 631 and 7.2.1.10 on p. 1606 for information about controlling dimensions).

When saving links between objects of a dependent version and objects of the source one, it is impossible to edit objects of the dependent version individually. Accordingly, it is impossible to change values of variables created for these objects in the dependent version.

In order to handle the geometry of dependent versions using variables, user variables should be created (see Section 7.1.2.1 on p. 1576) and matched against the respective parameter variables of operations and dimensions.

The set of user variables of the source version is transferred to versions created on its basis. For more details about peculiarities user variables creation in versions, see Section 2.13.3.5.1.

Variables can be matched in the Variables Window (see Section 7.1.1.3 on p. 1571). The matching means that a user variable is set as the value of an operation parameter variable or dimension variable, i.e. the name of the user variable is entered in the **Expression** cell of the operation parameter variable or dimension variable.

Later on, you can set values for user variables. These values will be transferred to matching variables of operations' parameters and sketch dimensions' variables. As a result, the version's geometry will be changed.

To make sure everything is correct, create and match user variables in the main version of the model before creating other versions. In this case, each version of the model will have the same set of variables.

In order to specify different values of a variable for different versions, use the Document Manager. For more details about working with variables in the Manager, see Section 2.13.3.5.2.

2.13.3.5.1. User variable in a version

When creating a version, all variables of the source version are transferred to it (including user-defined variables), i.e. a set of variables is created which is identical to the set of variables of the source version.

Note the following specifics of transferring user variables to versions:

- ▼ a dependent version – link to the respective variable of the source version becomes the value of the user variable; this link replaces the contents of the respective **Expression** cell of the Variables Window (if a property is created on the basis of the user variable, the cell's contents will be transferred without changes and the link will not be created);
- ▼ an independent version – the transferred user variable is fully identical to the respective variable of the source version; contents of the **Expression** cell of the Variables Window is transferred without changes.

Later on, you will be able to add the user variable to any version created in the model.

If the version, to which a variable is added, has dependent versions, the new variable will be transferred to all these variables, since the **Create variable in dependent versions** option is enabled in the version setup dialog by default (see Section 9.1.11.10 on p. 1735). If you do not need to transfer variables, disable this option.

In order to transfer a user variable to dependent versions, you can use the **Apply to dependent versions** command. This command is available in the context menu of the user variable in the version with dependent versions.

In the model's Variables Window, you can edit user variables of dependent and independent versions. Note that the list of variables displayed in the Variables Window is related to the current version (see Section 2.13.3.1 on p. 761).

You can change the contents of the **Expression** cell of the required variable. This will result in changing the variable's value. This change will be transferred to dependent versions.

If a variable of a dependent version should have another values (other than the value of the source version's variable), replace the link contained in the **Expression** cell of the variable by the value you need. Link between variables of a dependent and independent versions will be lost. If necessary, you can restore it by creating the link to the variable of the required version (see Section 7.1.3.5 on p. 1583).

Values of user variables can be changed in the Document Manager for different versions (see Section 2.13.3.5.2).

2.13.3.5.2. Specifying the values of user variables

Values of user variables are set using the Variables Window (see Section 7.1.1.3 on p. 1571) or the Document Manager (see Section 2.13.1.3 on p. 752).

The Variables Window is used for setting values of user variables in the current version (peculiarities of values setting are described in Section 2.13.3.5.1).

If a model contains properties created on the basis of user values, you can use the Property Editor (see Section 5.1.4.2 on p. 1389) in order to set values of variables in the current version.

In order to set values of user variables for different versions, open the Document Manager and perform the following operations.

1. Choose a user variable, the value of which should be set.

For this purpose, click the **Insert Variable** button on the Manager's toolbar. The **Variables** dialog with the list of variables for the current version will appear on the screen (see Fig. 7.1.7 on p. 1584).

If the required user variable is present in the list of variables of another model's version, choose designation of the version in the **Version** drop-down list.

Specify the required user variable in the list of variables and click **OK**. The **Variables** dialog will close. A column will appear in the Document Manager table. Its name contains the name of the selected variable. And the property will be automatically created in document on the basis of the selected variable (see Section 5.1.3.2.1 on p. 1383).

The property created on the basis of the variable will be included in the set of the document's properties. You can edit it in the Property bar (see Section 5.1.4.1 on p. 1385) or in the Property Editor (see Section 5.1.4.2 on p. 1389).

If the property based on the required variables is already created in the document, you will not need to use the variable selection dialog. Customize displaying the column using the values of the property, as it is described in Section 2.13.1.3 on p. 752.

2. Cells of the resulting column are available for both independent and dependent versions of the model. Enter the required values in the cells.

Note that a change in the value of a variable made for a version is transmitted to all of its dependent versions that have the same value of the said variable.

3. In order to apply and transmit changes to the model before you finish working with the Manager, click the **Apply** button.
4. Click the **OK** button to close the Document Manager.

2.13.3.5.3. Extra options for working with variables

In some cases, when working with versions, you may need to set the value of an operation's parameter variable or of a variable of the sketch's controlling dimension. You can set values of these variables for an independent version or for objects of a dependent version that have no link to the source version's objects (for example, the link was canceled or object was created in a dependent version).

If you need the variable's value to be set for one version only, make the version the current one (see Section 2.13.3.1 on p. 761) and set the value of the required variable in the Variables Window. The values of variables are set for a version in the same way as for a model (see Section 7.1.3 on p. 1578).

You can also create a property on the basis of the required variable of the current version (see Section 5.1.3.2.1 on p. 1383) and set its value using the list of properties in the Property bar (see Section 5.1.4.1 on p. 1385) or in the Property Editor (see Section 5.1.4.2 on p. 1389).

If necessary, you can create properties on the basis of any variables, except for functional and interval ones. Peculiarities of setting values for properties created on the basis of variables are described in Section 5.1.4.4.5 on p. 1399.

If you need to specify values of an operation parameter variable or a sketch controlling dimension's variable for several versions, open the Document Manager, add the required variable (see Section 2.13.3.5.2) and specify its values for versions.

Changing the value of the operation parameter variable (dimension's variable) for a version will be transferred to its dependent version, if the link between the respective parameters (dimensions) of these versions is retained.

In case of a variable of the sketch's controlling dimension or a variable of an operation's parameter expressed in linear or angular values, you can set the value and assign a tolerance for the value of the respective parameter or a dimension tolerance. Assigning tolerances is described in Section 2.13.3.5.4.

2.13.3.5.4. Viewing and assigning tolerances when working with variables.

When working with variables in the Document Manager (see Section 2.13.1.3 on p. 752), you can view individual tolerances assigned to variables of sketch controlling dimensions and to variables of operations' parameters whose values are expressed in linear and angular values (more information about individual tolerances can be found in Section 2.10.2 on p. 667).

If the column with values of the required variable is not displayed in the Manager, add it using the **Insert variable button** (see Section 2.13.3.5.2 on p. 766) or customize the column display parameter (see Section 2.13.1.3 on p. 752), if a property is created on the basis of this value in the document.

By default, assigned tolerances are not displayed in the cells of the Document Manager's table. In order to enable displaying individual tolerances, click the **Display individual tolerances button**. If the button is enabled, values of parameters (dimensions) are displayed in the cells, as well as classes of accuracy and maximum deviations of parameters (dimensions). To disable displaying the tolerances, disable the button.

If the **Display individual tolerances** button is enabled, cells of variables of sketches' controlling dimensions and of operations' parameters, whose values are expressed in linear and angular values, will not be available for manual entry.

The Document Manager makes it possible to assign tolerances for the above-mentioned dimensions and parameter values.

Tolerance can be assigned to objects of an independent model's version or to dependent version's objects that have no links to the objects of the source version.

In order to assign a tolerance, complete the following steps.

1. In the variable's column select the cell that corresponds to the required version.
2. Call the dialog for assigning tolerance using one of the following methods:
 - ▼ if the individual tolerance display mode is enabled in the Manager, click the ellipsis button in the right section of the selected cell or double-click it.
 - ▼ if the individual tolerance display mode is disabled, call the **Assign tolerance** command from the selected cell's context menu.

After calling the command, the **Value and tolerance** dialog appears on the screen (Fig. 2.13.6).

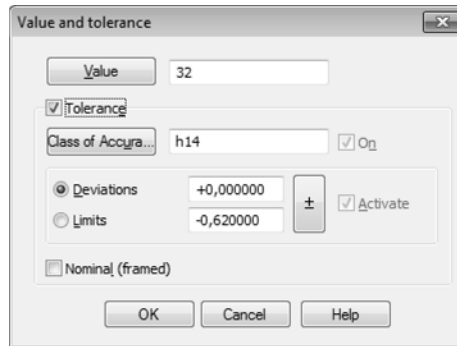

Fig. 2.13.6. The **Value and tolerance** dialog

3. In the appearing dialog, perform the required actions to set a tolerance. These operations are similar to those described in Section 2.10.2.2 on p. 669.

The dialog also makes it possible to set the value of the parameter or dimension to which the variable is related. It contains the **Value** field and the respective button (the button is present in the dialog for linear dimensions and parameters whose values are expressed in linear values).

Enter the value in the field or choose in the user menu that appears on the screen after clicking the **Value** button. By default, the menu contains normal linear dimensions according to GOST 6636-69.

If the value of a variable of a parameter or dimension is given in the form of an expression, you cannot change the value in the tolerance assignment dialog. The **Value** field and a same-name button are not displayed on the dialog.

4. Click the **OK** button to close the dialog.

The dialog will close. This value will be displayed in the Document Manager. If the **Display individual tolerances** button is enabled, the assigned tolerance will also be displayed in the Manager.

Values and tolerances specified for a version are transferred to all of its dependent versions after clicking the **Apply** or **OK** button in the Document Manager.

If you need to assign another tolerance to a parameter's value or dimension, cancel the link between the respective object of this version and the object of the source version.

The assigned tolerance is stored as maximum deviations of the parameter (dimension) in the Document Manager.

2.13.3.6. Additional numbers of versions

If a model's versions, aside from constructive differences, have such variable characteristics that may be shared by several versions (coating type, additional components of an item, and so on), additional numbers are created in the model.

Each additional number corresponds to a certain set of variable data. This data is set as values of additional numbers' attributes.

In order to create the list of additional numbers, perform the following steps.

1. Open the Document Manager (see Section 2.13.1.3 on p. 752).
2. In the Manager's tree, enable the **Additional numbers** element.
3. In the Manager's toolbar, click the **Create additional number of version button**.

The new additional number appears in the Manager. It will be formed in accordance with the settings (see Section 9.2.7.4.3 on p. 1845). If necessary, you can change the settings. These changes are taken into account only when creating new additional numbers.

4. Specify values of the additional number properties. For this purpose, make preliminary settings for the display of columns using **Column settings** and **Delete column** buttons (see Section 2.13.1.3 on p. 752). Values of properties are entered in the Manager's table cells.

If necessary, you can add columns with external variables and set values of the variables. Adding external variables and specifying their values are the same as operations described in Section 2.13.3.5.2 on p. 766.

5. In the same way, create all additional numbers you need and specify values of their properties. The list of additional numbers is displayed in the Manager as a table. The table cells are available for manual entry. If necessary, you can change the created additional numbers.

Besides that, you can change the order of the additional numbers in the list. Changing the additional number's position is described in Section 2.13.2.3 on p. 760.

In order to create additional numbers in the model, you can use another model's list of additional numbers saved in the *ods* or *xls* file. The numbers and values of their properties are added to the current model from the file.

If the model has a number identical to the number in the file (not only the numbers are the same, but values of their properties are also identical), the number will not be added to the model from the file.

Generating additional numbers using this method is identical to the procedure described in Section 2.13.2.2.3 on p. 759.

6. Click the **OK** button to close the Document Manager.

Variable data corresponding to additional numbers is presented as a table of additional numbers in a graphical or text document. In order to create the table, you can use the model or the associative view of the model created in a drawing.

The table of additional numbers is created by the **Create table of versions** command. The same set of controls is used for creation of both tables (versions and additional numbers). In order to create a table of additional numbers as a result of executing the command in a graphical or text document, select the **Table of additional numbers** table type in the dialog for table parameters setup (see Section 2.13.4.2 on p. 775).

All activities related to creation of the table of additional numbers are the same as activities related to creation of the table of versions (see Section 2.13.4.1 on p. 772).

Working with the created table of additional numbers is identical to working with the table of versions (see Section 2.13.4.3 on p. 776).

2.13.3.7. Saving a model with versions

Saving a model with versions is a process identical to saving a model without versions.

When saving a model with versions in KOMPAS-3D formats, information about all of its versions is saved.

When saving a model with versions in other formats, only information about the model's current version is saved.

You can also save any version in a separate file. For this, do the following.

1. In the Tree of Versions, call the **Create copy** command from the context menu of the required version. The **Information about document** dialog will appear on the screen.
2. Enter the required reference information in the dialog and click the **OK** button. Windows-standard File Save dialog will be displayed.
3. Specify the required name and location of the file on disk and click **Save**.
Only the selected version will be saved to the file. It will be the main one in the resulting file.

2.13.4. Table of versions

Information about versions' variable data is presented in the table of versions. In order to create the table of versions, you can use the model or the associative view of the model created in a drawing. The procedure of creating the table can be found in Section 2.13.4.1.

The table of versions can be located in a graphical or text document. You can edit data in the table, change its header, location and so on.

If the table of version is associatively linked to the source of data (a model or a model's associative view), you can retrieve data from the source document, open it, use commands for editing available for associative reports (see Section 5.2.3.8 on p. 1433). These operations are not available for the table which is not related to the source of data.

Working with the table of versions is described in Section 2.13.4.3 on p. 776.

Parameters of the table of versions are set during its creation or editing (see Section 2.13.4.2 on p. 775). Text of the table of versions located in a graphical or text document is displayed in accordance with the setup of text parameters of the report's table applied to that document (see Sections 9.2.4.7 on p. 1754 and 9.2.6.23 on p. 1835).

2.13.4.1. Creation of table

In order to create a table of versions, do the following.

1. Open a model or a drawing containing the model's associative view.
2. If the table is being created in a drawing, specify the required model's associative view. If the required view is not selected by the user, the current associative view will be automatically selected to create the table.

3. Call the **Create table** of versions command from the **Service — Reports** menu or using the respective button on the **Reports** bar.

Table creation elements will appear on the Property bar. They are located in two tabs: the **Table of versions** and **Components**.

Besides that, the **Parameters of table versions** dialog will be opened automatically for adjusting the table's appearance (see Section 2.13.4.2 on p. 775).

4. Customize the required settings in the **Parameters of table of versions** dialog and close it by clicking **OK**. Later on, you will be able to call the dialog by the **Setup...** button. Property Bars.
5. After calling the table creation command, the **Table of Versions** tab on the Property Bar will be activated (Fig. 2.13.7). Set the order of version designations' displaying in the table using the **Designation** switches on this tab.

Fig. 2.13.7. Properties panel when creating a version table.
Table of versions tab.

By default, the **Only numbers of versions** switch is enabled. Full designation will be displayed for the first version in the table, while only numbers of designations will be displayed for other versions.

If you need the designation of each version to be displayed in full, enable the **Full designations** switch.

6. Check status of the **Associative table** option.

If the option is enabled, the table of versions will be associatively linked to the document being the source of data. If values of versions' properties will be changed in the source document, you will be able to reflect these changes in the table of versions (see Section 2.13.4.3 on p. 776).

If the option is disabled, the non-associative table of versions will be created. In this case, the data modified in the source document will not be transferred to the table.

If the table of versions is created for a model, the **Associative table** option will be available on the Property bar only if the model is saved to file on disk.

The associative table can be located in a graphical document only. If located in a text document, the table will become non-associative irrespective of whether the option is enabled or not.

7. You can enable automatic assignment of numbers to report tables. For this, select a numbering group on the **Numbering** list (about automatic numbering, see Section 3.9.1 on p. 1277).
8. When creating an associative version table for an associative view from a model in the drawing, you can link the table with the title block of the drawing (see Section 2.13.4.1.1 on p. 774).
9. If you need the list of the model's versions to be displayed in several tables rather than in one table, go to the **Components** tab (Fig. 2.13.8).

Fig. 2.13.8. **Components** tab

10. You can have several tables by enabling the **Split table** option.
11. In the **Number of rows** in table, specify the maximum number of rows in each table. In accordance with the value, the general list of versions will be divided into several lists; each of them will be placed in a different table. Display parameters are the same for all tables.
12. To specify the order of tables' positioning on the sheet, choose the required direction of positioning from the **Contents** drop-down list.

The **To the right, then downwards** option positions tables in horizontal rows. The number of tables in a row is specified in the **To the right, not more than** field.

The **Downwards, then to the right** option makes it possible to position tables in vertical rows. The number of tables in a row is specified in the **Downwards, not more than** field.

13. The **Gap, mm** field makes it possible to specify distance between the tables. You can enter the required value of the distance manually or select it from the drop-down list.

14. In order to finish creating the table, click the **Create Object** button.

If the table is being created for the model's associative view in a drawing, the drawing's field will display the table's ghost. Specify the location of the table's snap point using cursor or by entering coordinates in the Property Bar and click the left mouse button to fix the table. The table is placed in the associative view chosen for its creation.

If the table is being created in a model, the file open dialog will appear on the screen. Open the required graphical or text document. Locate the ghost of the table in the graphical document as described above. In a text document, the table is located automatically.

When creating the table of versions in a drawing, you can re-select the associative view for which the table is being created before the you finish working with the command. For this, all you need to do is click the desired view on the Tree or in the drawing window.

You can set a title for a table placed in the drawing, see Section 4.2.2.1.3 on p. 1364.

2.13.4.1.1. Link the drawing's title block to the associative table of versions

If there is a table of versions in the drawing with columns having *Material* and *Mass* properties, the cells of the drawing's title block that correspond to these properties should contain text indicating that the required data is contained in the table instead of the properties' values (for example, text as in *see Table*). This text is generated automatically.

- ▼ when the table of versions is created for the model's associative view (see Section 2.13.4.1 on p. 772),

- ▼ when the table of versions in a drawing is being edited by the **Edit table** command.

Text of the link to the table of versions can be generated only the table is an associative one (the **Associative table** option is enabled during creation of the table).

In order to create the link's text, the elements of the **Table of versions** tab in the Property bar are used (see Fig. 2.13.9).

Fig. 2.13.9. Link formation elements

Links are created with the **Links in title block** option enabled. The field on the right of the option contains the default text of the link. If necessary, you can edit the text.

If the version table has a number automatically assigned to it (i.e. in the **Numbering** list, an item other than **Do Not Use** has been selected), the number must be added to the reference text. To do this, enable the **Add the table's number** option.

Only the number is added to the link's text; the text before and after the number which is assigned during the numbering parameters setup (see Section 9.2.6.22 on p. 1832) is not added.

Once the process of creation and editing of the table of versions is finished, contents of *Material* and *Mass* cells of the drawing's title block will be replaced by text of the link to the table. It happens if the table of versions contains columns of their respective properties. If a column of

a property, for example, the *Mass* property is not present in the table, the link's text will be displayed only in the *Material* cells, while the value of the respective property will be displayed in the *Mass* cell.

2.13.4.2. Setup of a table's parameters

The parameters of the table of versions are set up in the dialog illustrated in Fig. 2.13.10.

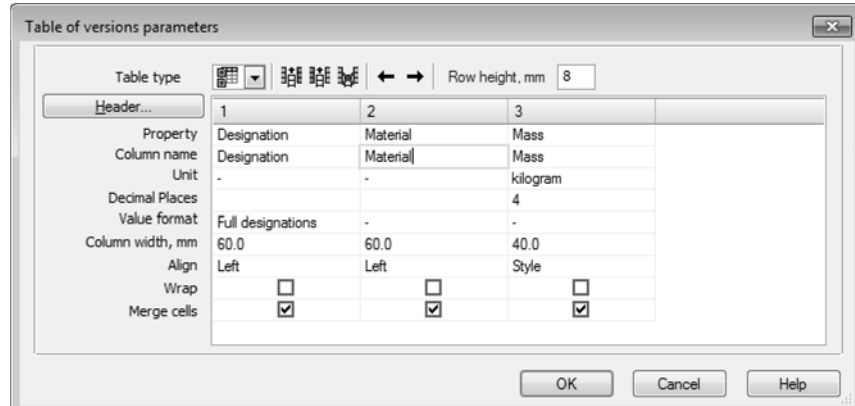

Fig. 2.13.10. The dialog for setup of the table of versions' parameters

The dialog is called when the table of versions is being created or edited by clicking the **Customize...** button on the **Table of versions** tab of the Property bar.

Besides that, the dialog appears automatically after the **Create table of versions** command is called.

The dialog contains a window for the table setup and a toolbar.

It is designed not only to set up parameters of the table of versions, but also for the table of additional numbers (see Section 2.13.3.6 on p. 770 for more information about additional numbers). The type of the table for setup is selected in the **Table type** drop-down list located in the dialog's toolbar. The set of the dialog's controls depends on the selected type.

As part of the table of versions setup, the following activities are available.

- ▼ Adding, deletion, and moving of the table's columns; controls are the same as those used for the report table setup (see Table 5.2.2 on p. 1408).
- ▼ Setup of the table's columns display parameters and data contained in them (see Section 2.13.4.2.1).
- ▼ Setting the table's row height. For this purpose, the **Row height, mm** field is used. The value is manually entered in this field.
- ▼ Setup of the table's header (see Section 5.2.2.2.4 on p. 1411).

In order to finish setup of the table's parameters, click **OK** in the **Parameters of table of versions** dialog.

If the list of versions is presented in several tables, each of them will be displayed in accordance with the setup. The created header will be contained in each of the tables.

2.13.4.2.1. Setup of displaying the table's columns

The following parameters can be adjusted in version table columns:

- ▼ **Property, Column name, Unit, Decimal points, Column width, mm, Alignment, Wrap**; the setup is identical to the setup of the report style parameters which is described in Table 5.2.3 on p. 1410,
- ▼ **Value format, Merge cells**; the setup is described in Table 2.13.1.

Tab. 2.13.1. Additional setup parameters of the table of versions

Element	Description
Value format	<p>This field* makes it possible to choose the variant of displaying a property's value in the table of versions. For example, the following display options are available for the <i>Designation</i> property.</p> <ul style="list-style-type: none"> ▼ <i>Full designations</i>, ▼ <i>Only version numbers</i>. <p>Choosing the required option for the property is the same as using the Designation switch in the Property bar.</p>
Merge cells	<p>This option makes it possible to merge adjacent cells in a column of the table of versions, if the cells' contents is identical, i.e. if the displayed property has the same value for adjacent versions.</p>

* The control allows to select an option from the drop-down list. After you click a cell, in its right corner there appears a button with a triangle. Press the button to display the list for selecting a parameter option.

2.13.4.3. Working with the table

The table of versions can be associatively linked or not linked to the source of data. The table's associativity is defined during its creation (see Section 2.13.4.1 on p. 772). If necessary, you can cancel the associative characteristic of a created table as is described in Section 5.2.3.8.3 on p. 1436, but it is impossible to make a non-associative table to be the associative one.

Typical commands are used for handling non-associative tables.

In case of associative tables, both typical commands (for example, cutting, copying, changing style) and special commands are available that are the same as commands for handling the associative report.

The associative table of versions is linked to the model or the model's associative view which was used for its creation. It is displayed in the same way as the associative report in an additional external dashed frame (see Fig. 5.2.14 on p. 1434).

If the associative table is divided into several tables, all of these tables are a single objects and will be displayed within a common frame.

You can update data in the associative table, open the source document for editing objects, change the table's snap point. These operations are similar to those described in Sections 5.2.3.8.1 on p. 1434 and 5.2.3.8.2 on p. 1435.

In order to edit an associative table, the **Edit table** context menu command is used (the menu is called for the highlighted table). The command can also be called by double-clicking the external frame of the table. After calling the command, table edit elements appear on the Property bar. When editing a table, you can perform the same operation as when creating it (see Section 2.13.4.1 on p. 772), except for enabling/disabling the associative attribute.

In order to finish creating the table of versions, click the **Create Object** button in the Property bar.

Apart from the above-mentioned activities, you can also specify the name of the associative table or tables into which it is divided. For this purpose, highlight the associative table and call the **Name...** command from the context menu. The dialog for table name entry will appear on the screen. Working with the dialog is described in Section 4.2.2.1.3 on p. 1364.

The data contained in the table, both associative and non-associative, can be edited in the document's field. In order to enable the edit mode, double-click the table (in case of the associative table, you can click anywhere, except for the dashed frame). This mode supports all tools for handling tables (see Section 4.2.1.1 on p. 1349).

2.13.5. BOM for assembly with versions

2.13.5.1. Creation of a BOM for assembly with versions

In order to create a BOM using an assembly with versions, you can use any of the following commands:

- ▼ **Create BOM for assembly** (see Section 6.2.3.8 on p. 1506).

This command generates internal BOM objects in the assembly and creates a BOM document connected with the assembly. BOM style is defined by the settings for new BOMs for assemblies, see Section 9.2.5.2.1 on p. 1758. By default, for assemblies with no more than 3 versions, the group BOM under A variant (GOST 2.113–75) is used, while for assemblies with more versions, BOM of the B variant is used (GOST 2.113–75, F.1, 1c). If necessary, you can change the default settings.

- ▼ **Create BOM objects** (see Section 6.2.3.7.1 on p. 1504).

This command forms BOM objects in assembly components, creates and saves the BOM document connected to the assembly (optionally). BOM style is defined by the general settings for new BOMs for assemblies, see Section 9.2.5.1.1 on p. 1755. By default, for new BOMs, the *Simple BOM (GOST 2.106–96)* style is used; therefore, before applying the **Create BOM objects** command to the assembly with versions, the setting should be changed by selecting one of the styles for group BOMs as the default one.

2.13.5.2. Components with identical position numbers

Sometimes it is required that certain components in BOMs for different assembly versions have the same position number. Normally, it is required for components that perform the same func-

tion but represented by different models in different assembly versions (or by different model versions).

To assign the same position number to some KOMPAS-3D assembly components, they have to be combined into a *group of components with the same position*. There can be several such groups in a single assembly. Once component may be included in one group only. Information about groups of components is stored in the assembly file.

All components included in a single group will have the same position number in BOM.

Groups are handled in the **Component groups** window. In order to enable/disable it, the respective button in the **BOM** bar is used. The **Component groups** window's interface and methods of working with it are described in Section 2.13.5.2.1.

Procedure for forming a group of components is described in Section 2.13.5.2.2.

If an assembly contains several identical components, it is not obligatory to include them in a single group. For example, only four out of ten bolts can be included in the group. As a result, these four bolts will have the same position number, while other bolts will have different position numbers which is defined by objects' sorting within BOM.

2.13.5.2.1. Component groups window

The **Groups of components** window (Fig. 2.13.11) is used for working with groups of components that must have the same position number in the BOM. You can enable and disable displaying the window by clicking the **Component groups** button in the **BOM** bar.

Fig. 2.13.11. **Component groups** window

The main part of the **Component groups** window is occupied by the list of components included in the current group. The list is represented as a table: in the first column, designations of assembly's versions are displayed; in the second column, designations of components included in these versions, the positions of which should be identical. Upon selecting a component in the list, it is highlighted in the Model window.

Above the list of components, there is the **Component groups** window's toolbar. Its buttons are only available when working with an assembly.

Above the toolbar, there is a field with the list for selection of the current group. Groups in the list are sorted in alphabetical order.

Methods of working with the component groups are described below.

In order to save the results of working with component groups to the model's file, the file should be saved. It is impossible to undo operations when working with groups; therefore, in order to cancel creation/deletion/modification of groups, the assembly file should be closed without saving.

Creation of a component group

In order to create a new group of components, click the **Create group** button on the toolbar of the **Component groups** window. A dialog for new group name entry will appear on the screen. Enter the group's name and click the **OK** button in the dialog. The dialog will be closed, the created group will be added to the list of groups; it will be automatically made the current one. The new group does not contain components, therefore, their list is empty.

It is impossible to rename group components.

Removal of a component group

In order to delete a group (or groups) of components, click the **Remove group** button on the toolbar of the **Component groups** window. The **Remove groups** dialog will be displayed (Fig. 2.13.12). Perform one of the following actions in it:

- ▼ in order to delete all groups, choose the **All** option,
- ▼ in order to delete one or several groups, choose the **Groups** variant and specify groups for deletion in the dialog's list.

After that, click the **OK** button in the dialog. By default, the **Groups** option is enabled in the dialog, and the group that was the current one when the dialog is called will be highlighted.

Fig. 2.13.12. **Delete groups** dialog

Removal of a component group from the assembly means deletion of information about this group from the file. Components included in the group will remain in the assembly in their positions.

Adding components to a group

In order to add components to the current group, select them in the Design Tree and click the **Add to group** button in the toolbar of the **Component groups** window. Designations of an assembly's version and of the selected components appear in the **Component groups** window's list.

If components being added are included in a different group, they will be automatically removed from this group.

As a rule, components of different assembly versions are included in the group; however, if necessary, you can create groups of a single version's components, as well as create component groups in assemblies without versions.

Removal of a component from group

In order to delete a component from the group, select it in the list of the **Component groups** window and click the **Delete** button on this window's toolbar.

Designation of the component will disappear from the list.

2.13.5.2.2. Forming a group of components with one position in an assembly

Forming a group of components in an assembly consists in creating a new (or selecting an existing one) group and including the required components from different versions.

In order to create component groups with the same position in an assembly, perform the following steps.

1. Enable displaying of the **Component groups** window.

2. Create a component group. To do this, complete the following steps:

2.1. Click the **Create group** button in the **Component groups** window's bar,

2.2. in the appearing dialog, enter the new group's name and close the dialog with the **OK** button.

3. Add components to the group. To do this, complete the following steps:

3.1. Make current that of the assembly's versions which contains components with the same position numbers as components in a different version.

3.2. select these components in the Design Tree and click the **Add to group** button in the toolbar of the **Component groups** window.

The selected components will appear in the table: in the **Version** column, the assembly's version designation is displayed; in the **Object** column, component designations are displayed (see Fig. 2.13.11).

3.3. Perform steps described in paragraphs 3.1 and 3.2 with respect to other components that should have the same position number as components that have already been added to the current group.

4. Call the **File — Save** command so that information about component groups is saved in the model file.

If the group, to which components should be added, already exists, activate the required group instead of creating the new one. For this purpose, choose its name from the list of groups.

2.14. Model Editing and Setting Up

2.14.1. Managing the state of objects Displaying

2.14.1.1. Enabling and disabling of the object visibility

The auxiliary (construction) axes and planes (especially when there are many of them in the model), the sketches, components and other objects not being used by any operations sometimes obstruct the model view. For a more convenient when working with the model you can make any of these items invisible. It will still be considered in hierarchy, and its derivative items will be displayed correctly.

You can manage visibility of the following objects:

- ▼ individual within an object (see 2.14.1.1.1),
- ▼ any auxiliary objects or groups of the auxiliary objects of the same type (see 2.14.1.1.2),
- ▼ any objects within a layer (see 2.14.1.1.3).

2.14.1.1.1. Managing visibility of individual components

To hide one or more items, select them in the Design Tree or in the model window and use the **Hide** command from the context menu. The objects will become invisible. Their respective icons will remain at their places in the Construction Tree, but will be displayed in gray color.

To make a or several object components, select them in the Model Tree and use the **Show** command from the context menu. The objects will become visible.

Please note that the body is always hidden and revealed completely even if a separate shape-forming operation was selected while calling the **Show** or **Hide** command. For instance, on executing the Show Boss-Extrude command all the bodies which contain this element will be displayed whereas Boss-Extrude Hide command will hide the entire body.

The same is true for surfaces. For instance, as the result of showing or hiding the surfaces which are involved in the **Knitting** operation, all other surfaces involved in this operation will be shown or hidden in the model window.

Upon calling the **Show** or **Hide** command for all other items (auxiliary axes, curves, points, etc.), only these items will be shown or hidden in the model window.

The **Hide (Show)** command is not available if all the selected objects are already hidden (shown).

Using the **Hide** or **Show** command for an object changes the *Visibility* attribute of this object to **Hidden** or **Visible** respectively. You can also edit this attribute manually without calling this command. To do this, use the **Properties** window, see Section 1.4.2.2 on p. 82.

2.14.1.1.2. Managing visibility of auxiliary components

To hide all the auxiliary objects in the model, click **Hide all objects** on the **View** panel. To hide the auxiliary objects of a certain type, call the corresponding command from the drop-down

menu of this button (Fig. 2.14.1). Upon calling any of those commands all the objects of the respective type, both existing in the model and the new ones, will be hidden. Hidden component icons are displayed in gray in the Design Tree. The button adjacent to the command name in the menu switched to pressed indicating that all the objects are hidden.

If there are any components in the model, you can customize visibility of each component. To do this, use the **Hide all objects in the components** button on the **View** panel. The button menu is identical to **Hide All Objects** button. The difference is that the **Hide all objects in components** command can be applied to the assembly components only whereas **Hide all objects** can be applied to both the assembly and its components.

To display the hidden auxiliary components, call the hide command once again.

The objects hidden using the above commands cannot be displayed by means of the **Show** command since it is not available in the context menu of these objects. You cannot change the *Visibility* attribute of these objects in the **Properties** window.

The menus of **Hide All Objects** and **Hide All Objects in Components** may be used for building separate instrument panels (see example in Fig. 2.14.2) to be used instead of menus. To do this use the mouse to drag the button menu by the header in the required direction.

Fig. 2.14.1. Defining object type for hiding

Fig. 2.14.2. **Hide** Panel

Please note the difference between **Hide** and **Hide in Components** panels from the rest of the instrument panels: you cannot change the composition or the order of buttons on them.

2.14.1.1.3. Managing visibility of objects in a layer

You can manage visibility of the objects using the layers (for details about layers, see Section 2.15.13 on p. 845).

You can hide or display objects located in the same layer at once by editing the *Visibility* attribute of this layer.

Note that the *Visibility* attribute of each object must set to **By layer**, otherwise changing the layer's attribute will not affect the object's attribute.

The **By layer** is the default value of the *Visibility* attribute for all objects.

If the *Visibility* attribute of an object is not set to default value, that is, is set to **Hidden** (or **Visible**), then the object is hidden (or displayed) independently of whether its layer is visible or not.

To view or change the object attributes, use the **Properties** window, see Section 1.4.2.2 on p. 82.

2.14.1.2. Excluding Objects from Calculations

You can exclude from calculations any model features and components. When excluding an object from calculations, the model rebuilds so as if the specified object is deleted, however the information about it is still kept in the document.

To exclude one or several objects from calculations, select them in the Construction Tree and call the context menu command **Exclude from Calculation**.

After calling the command, the model will be rebuild, excepting the excluded objects and their dependent operations and objects. The icons of the objects excluded from calculations will be displayed in gray and marked with a 'cross' in the Construction Tree.

Objects excluded from calculation are temporarily removed from the model. Hence, the objects referencing them can sometimes be marked as failing objects. Errors disappear after including objects into calculations.

To re-enable the inclusion of one or several objects into calculation, select them in the Construction Tree and call the context menu command **Include into Calculation**.

Excluding objects from calculations helps to save calculation time when building additional elements or rebuilding the model, as well as to see how the model looked like before creating certain elements.

For example, after creating a sequence of dependent elements, you need to proceed to creating other elements that are not related and do not intersect with the existing ones. You can exclude the existing sequence from calculations, after which the model rebuilding time will significantly shorten when creating new elements (the system will not run checks for intersection on all elements and calculate the intersection lines). When the required elements are created, include the rest of elements into the calculations. Their relative position check will be run just once.

You can exclude from calculations chamfers, fillets, holes and other small elements, if, due to their large cumulative number, new geometry-producing feature creation is too slow.

Using **Exclude from Calculation** command, you can exclude objects from calculation selectively, i.e. regardless of their position in the hierarchy of model features and, accordingly, in the Construction Tree.

Remember to include in calculations all model elements when finishing a model development!

There can be examples not only of excluding features temporarily from calculation, but only of including features temporarily in the calculation.

Sometimes, when generating a flat model view (e.g. its isometric view in the drawing or a dimmed image in the folder), you will need to show a cut in the model (for example, a 1/4 cut

in the model). After the model has been created, do a trimming by sketch. Save the model file. Generate the desired model view. To continue working further with the model (for example, to calculate its mass-inertia properties or transfer the model to a process control sequence generating application), exclude the trimming operation from the calculation.

2.14.2. Color and properties control of item surfaces

You can also set the color and properties of the surface (flares, transparency, etc.) both for the entire model and its objects: components, bodies, surfaces, operations, faces, etc. For objects without surfaces, such as curves or points, you can only set the color.

To set a color and properties of the object's surface, select it in the Design Tree or in the model window and choose **Properties** from the context menu (**Model properties** for a model, or **Component properties** for a component).

To set the color and properties of the edge surface, you can use the **Face properties** command from the context menu of the edge currently selected in the model window.

If a part of an object is selected in the model window, e.g. an edge of an operation or a curve's segment, then the **Source item properties** command will be available in the context menu. Using this command, you can customize the properties of the parent object.

Once you call the command, the Properties panel will display the object properties controls, including the **Assign color** group of switches and the **Optical properties** panel with the sliders to adjust the optical properties of the surface (Fig. 2.14.3).

Fig. 2.14.3. Controls for adjusting the color and properties of the object surface

The available items in the **Assign color** group depend on the type of object you're configuring. The switches in this group are described in Table 2.14.3.

Tab. 2.14.1. Switches in the **Assign color** group

	Switch name; objects it is available for	Result of applying the switch
	By Source Object available for all objects	<ul style="list-style-type: none"> ▼ A faces is displayed in a color which corresponds to the operation resulted in this face. ▼ The operations, bodies, surfaces, curves and other model objects are displayed in a color specified for the model (or a variant, if any).
	By source available for operations and components.	<ul style="list-style-type: none"> ▼ Each operation is displayed in a color specified for a body (or a surface) built as a result of this operation. ▼ Each component is displayed exactly as it appears in its file.
	By layer available for objects that can be placed in layers. layers* (i.e. all objects except operations and faces).	The objects are displayed in colors specified for their layers.
	Manual setting available for all objects	Each object is displayed in a color specified by a user.

* For details about layers, see Section 2.15.13 on p. 845.

When setting colors and properties of surfaces, keep the following in mind:

- ▼ A color and properties of a model are always set manually. So, when you configure the group properties, the **Assign color** group is not available on the Properties panel, and only the **Color** field and the **Optical properties** panel are shown. When configuring all other objects, keep the following in mind:
 - ▼ The **Color** field is available only when the **Manually** switch is enabled.
 - ▼ The **Optical properties** panel is available, only when the **By source object**, **By layer** (in this case the properties cannot be edited and are given for information only) or **Manually** switch (in this case the properties are editable) is enabled.
- ▼ You can change the color and properties of the surface for the components of the first level only. When configuring the components of other levels, the controls for surface color and properties are not available on the Properties panel.

After the color surface properties have been adjusted, confirm the changes made.

After that, the image in the window will be re-drawn according to set parameters.

You can also change the color and properties of the object surface in the **Properties** window (see 2.14.3.6.1 on p. 793) by setting the appropriate values to the *Color designation*, *Color* and *Optical properties* properties.

In the **Properties** window, you can customize several objects at once. For example, you can select several edges of a part or components in the assembly and set their color.

Sometimes parallel edges of a body merge in halftone image. To facilitate perception of such an image, properties of parallel faces may have different settings (often it is sufficient to change shininess or diffusion without changing color).

2.14.3. Editing model objects

When editing a model, you can change any parameters of its nested objects. This section describes all editing methods available for the objects.

Note that you can edit only objects directly included into the current model. You cannot directly edit the objects of the components within this model. To edit the objects in the component, you can either open it in a separate window (see Section 2.11.6.1 on p. 722) or enable the context editing mode for the component (see Section 2.11.6.2 on p. 723). Then you will be able to edit objects without any limitations.

When editing objects in a model, the hierarchical relations between them are not changed, i.e. you don't need to reconfigure the sequence for the child objects and their parameters after changing the parent object.

In some cases, a model is rebuilt automatically. For example, when you change a contour in a sketch, the system automatically adjusts the shape of the underlying extrusion object. In other cases, e.g. when the values of variable are changed, you should call a certain command to rebuild a mode, see Section 2.14.3.7 on p. 795.

Changes that you make when editing a model are copied into all parent models.

2.14.3.1. Editing a Sketch

2.14.3.1.1. Editing an image in a model's sketch

You can edit a graphical image in any model sketch.

You need to select a sketch before calling the sketch editing command. This can be done in one of the following ways:

- ▼ Select the sketch in the Construction Tree,
- ▼ Select an operation based on the sketch in the Construction Tree,
- ▼ Select any face of an object based on the sketch in the Model Window

Then call the context menu command **Edit Sketch**.

The system enters the sketching mode.

At the same time, only those objects will be left in the part window that are located before the edited sketch in the Construction Tree. In other words, the model will temporarily return to the state in which it was at the time of the edited sketch creation.

When making changes to a sketch, you can project (map) on it the existing objects (edges, faces, etc.), snap to model objects, add and delete parametric relations and constraints, perform any constructions, edit graphical objects.

If the sketch is parametric and the object positions in it are defined by associative dimensions, you can enter new values for those dimensions.

Remember that the sketch for an operation must meet certain requirements. These requirements shall be met not only when creating the sketch, but also when editing it. Specific requirements to sketches are given in Sections devoted to operations.

After the desired changes to the sketch are made, leave the sketch editing mode. The object formed on the basis of the sketch and its derived objects will be rebuilt in accordance with the contour modification in the sketch.

We do not recommend making such changes to a sketch, that will certainly cause a failure in rebuilding dependent objects.

2.14.3.1.2. Positioning Sketch on the Plane

In some cases, it may be required to change the position of the sketch on the plane (flat face) or select another plane (flat face) for the sketch. To do so, select the sketch in the Design Tree and call the **Locate sketch** command. The sketch placement elements will become available on the Properties Bar (see Fig. 2.1.23 on p. 141).

If graphic objects in a sketch have parametric relations with an auxiliary model object projections (see Section 2.2.2.3.1 on p. 146), a prompt will be displayed about the possible loss of those relations after changing the sketch plane. You can continue positioning the sketch or cancel it.

To select another plane (flat face) to place the sketch, select it in the Model Window. The location of the sketch will change and the name of the selected object will appear in the **Base Plane** field on the Properties Bar.

For relocating a sketch on the plane, the **t** and **Angle** fields are used. You can specify the new position of the selected sketch's coordinate system and the rotation angle of the new coordinate system in relation to its current position. The new coordinate system's position can be adjusted in the window using the cursor. To do so, you first need to unfix the respective field — **t** or **Angle**. Upon unfixing either, the ghost of a coordinate system will appear on the screen.

The position of the sketched objects with respect to its own coordinate system will not change. Therefore, as the coordinate system moves, the sketch image would move as well. The changing position is displayed as a ghost.

If you do not need the sketch to be related to the base plane, enable the **Independent Location** option. The sketch will keep its position in space, but its link with the base plane will be broken (the base plane will no longer be highlighted in the Model Window, and its name will be deleted from the **Base Plane** field). When the option is enabled, sketch location parameters are unavailable.

Disabling the **Independent Location** option restores the link between the sketch and the base plane.

To perform all the required actions, click **Create Object**. The object formed on the basis of the sketch and its derived objects will be rebuilt in accordance with the sketch's new position.

The **Locate Sketch** command is unavailable if graphic objects in the selected sketch have a parametric relation with previously created objects (e.g. handles of sketched line segments match with vertices of the face on which this sketch is built, or the sketch contains projections of existing edges) or if other parametric relation types prevent from moving graphical objects in the sketch plane.

2.14.3.2. Operation editing

A model's object is created by performing an operation. You can edit the created object by modifying the operation's parameters.

In order to modify parameters of an operation, enter the object editing mode. For this purpose, do any of the following:

- ▼ Select an object in the Construction Tree or in the Model Window and call the **Edit** command from the context menu.
- ▼ Select an object in the Construction Tree or in the Model Window and call the **Edit** command from the **Editor** menu.
- ▼ Select any face, edge, or vertex of an object in the Model Window and call the **Edit source element** command from the context menu.

The system will switch to the command that was used for building the selected object.

At the same time, only those objects will be left in the part window that are located before the edited object in the Construction Tree. In other words, the model will temporarily return to the state in which it was at the time of the edited object creation.

The Property bar will display the same fields and option buttons for setting parameters of the operation as when constructing an object. If reference or source objects were used for object construction, they will be highlighted in the Model Window and in the Construction Tree.

Edit the required operation's parameters (create new numeric values of parameters, modify the set of reference or source objects and so on).

If **Sketch Dimensions in Operations** option is on in the dimensions and symbols display settings dialog (see Section 9.1.11.12 on p. 1736), then sketch dimensions will be displayed and available for modification when editing features. To adjust the dimension, double-click the dimension text.

Confirm the adjustments by clicking **Create Object** button.

The object will be rebuilt according to the new parameters of the operation.

2.14.3.3. Editing numeric parameters of an operation

You can edit number parameters of an operation without entering its editing mode. For this purpose, you can use variables, corresponding to parameters of the operation, and operation's dimensions (see Section 2.9.2.2 on p. 632).

More information about editing variables related to operation's parameters can be found in Section 2.14.3.3.1 on p. 789. Details of editing operation's dimensions can be found in Section 2.14.3.3.2 on p. 789.

2.14.3.3.1. Editing a variable's value

One of the methods to edit an operation's numeric parameter is changing its variable's value in the Variables window.

In order to change the value of a variable, do the following:

1. Enable displaying of the Window of Variables. For this purpose, click the **Variables** button on the Standard bar.
2. Locate and expand the section corresponding to the desired object in the table in the Variables window.
3. Find the line of the variable being edited.
4. Click the **Expression** cell of the line and enter new value of the variable.
5. Press <Enter>.

In order to rebuild the model in accordance with the parameter's new value, click the **Rebuild** button on the **View** bar or choose its name from the **View** menu.

2.14.3.3.2. Editing dimensions of operation

One of the methods to edit an operation's numeric parameter is changing the value of the respective dimension of operation.

You can edit operation's dimension in the special mode (see Section 2.9.2.2.2 on p. 635).

In order to modify the value of operation's dimension, do the following:

1. Enable displaying dimensions of the selected element. For this purpose, click the **Dimensions of selected element** button on the **View** bar or select its name in the **View** menu.
2. Highlight the required object in the Construction Tree or specify any primitive of this object in the Model Window: a face, edge, or vertex.
Dimensions of the highlighted object will be displayed.
3. Find the required dimension and double-click its dimension text. The dialog to set the dimension value will be displayed.
4. Enter the dimension's value in the **Expression** field of the appearing dialog: a number, constant, or expression for calculation of the dimension's value. Syntax of expressions is described in detail in Section 7.1.3.3.1 on p. 1580.

5. Click the **Rebuild** button in order to enable automatic rebuilding of the model after closing the dialog.
6. Finish dimension editing by clicking the **Create Object** button.
The dialog will be closed, and the model will be rebuilt according to the value of the parameter.

More information about the dimension value setting dialog and its usage can be found in Section 2.9.2.2.1 on p. 634.

The value of a sketch's dimension can be changed outside the sketch mode. Modifying the value of a sketch's dimension is the same as modifying the value of an operation's dimension.

If operation's dimension is represented by a control element (i.e. derivative dimension is created see Section 2.9.2.8 on p. 648), you can edit the operation's parameter by changing the respective derivative dimension's value. Editing the value of the derivative dimension is the same as the editing procedure described above.

2.14.3.4. Editing Models Inserted from Library

After a library model is inserted in an assembly, you may need to edit it.

- ▼ If, on the other hand, the selected model does not have external variables, then to modify it you would need to edit the source model in the library (see Section 12.1.5 on p. 2045).

Refreshing model inserts (whether from libraries or models from disk) occurs automatically upon opening the main document.

- ▼ If a model inserted from the library has external variables, then, you need to edit their values in order to modify dimensions and the model topology (see Section 7.1.5.3.2 on p. 1593).

If a library model has a table of variables in addition to external variables, you can select new set of variable values from the table. You open the table of variables using **Table of Variables** command in the context menu of the library model in the Model Tree.

Sometimes, after editing the variables of a model, the latter is marked in the Design Tree as failing. That means the input external variable values make the system of equations relating the model variables unsolvable. To fix the error, edit variable values again.

- ▼ You can also replace a library model with a model from the disk (select another model insertion source).

To change the model insertion source, select it in the Design Tree and call the context menu command **Component Properties**. The dialog of new library settings will be displayed. The **Source File** field shows the path to the library file, from which the model was taken, and the model's name in the library. In order to change the source of the model's insertion, click the **Change...** button. In the appearing standard File Open dialog, select the desired model document.

A library part component can be replaced by a part only, an assembly component — by an assembly only.

The selected model will be inserted in the assembly instead of the library component, while maintaining the anchor point position. The library component icon will disappear in the Design Tree, instead, a part or assembly icon will appear in that place.

If an assembly has objects derived from a library model (for example, a construction axis was drawn through one of its vertices, or a part was built in the assembly context on one of the library model's faces), then, upon replacing the model insertion source, all relations, which arose from creating dependent objects, will be destroyed, and errors will appear in the model. Therefore, before you change the model insertion source, review this model relations to determine the derivative elements it has.

2.14.3.5. Features of Editing Individual Objects

The techniques of editing most features (deletion, parameter setting, selecting another reference objects, etc.) are the same. They are described in the previous sections.

However, certain objects have specific properties meaning there are additional techniques for editing such objects. They are described in this section.

2.14.3.5.1. Hole from a library; spiral; hole in sheet body

One of the features of the objects like a hole from a library, spiral and hole in sheet body is that when you create them, the system automatically generates a sketch in the model. The sketch contains an auxiliary point at the intersection of the object's axis and an edge (or plane) where it resides. We will call this point a central point of an object.

If the sequence of model building is displayed in the Tree (see Section 2.1.2.1 on p. 106), the position of objects in it will correspond to the order of creation, and the sketch with the center point will be positioned directly in front of the hole (or a spiral).

If the Tree displays the model structure (see Section 2.1.2.2 on p. 106), the sketch will be positioned in the Sketches section, whereas the hole will be located in the Body Section (or in Curves and Points section for spirals). In this case, the relations of the *Hole* object or *Spiral* (see 2.1.2.7.2 on p. 114) can be used for quick search of the sketch with the hole central point. The required sketch will be the first in the list of source objects *Holes* or *Spirals*.

Using this sketch, you can do the following:

- ▼ Change the position of an object on a face. To do this, select a sketch with a central point in the Design Tree (or the point itself in the model window) and then choose the **Edit** command from the context menu. The system will switch to the sketch editing mode. Move a point from the sketch to the destination using any method you like. You can use bindings, apply parametric limitation to the point or set the parametric dimensions to define the position of the point.

For example, if you need the hole to be positioned exactly in the center of a rectangular face, create an auxiliary line connecting the diagonal points of the face and snap the point to its middle. After that, the center of the hole will stay exactly at the center point of the face throughout any changes in the face dimensions.

After the desired changes to the sketch are made, leave the sketch editing mode. The object will be rebuilt to accommodate the new center position.

- ▼ Move an object to another face or surface. To do this, select a sketch containing the center point from the Design Tree and call the **Place sketch** command (see Section 2.2.2.2 on p. 145).

2.14.3.5.2. Dimensions and Symbols

In contrast to other objects in the model, dimensions and symbols can be edited without invoking the edit command, just using the mouse.

Select the dimension or symbol by clicking it in the model window or Construction Tree. The model window will show the selected object's handles. You can move them with your mouse in the dimension plane or symbol plane. In such a way, for example, you can move a dimension line or text, rotate the leader shelf, change the spot where the leader branching is pointing at, etc.

If a symbol is selected, this symbol's plane will also be displayed as a dashed rectangle. If a symbol plane was not fixed when the symbol was created (i.e. no fix object was specified), then one of the corners of the rectangle will show a handle that allows moving the symbol plane parallel to itself. When this handle is dragged with the mouse, the whole symbol will move. The plane can be moved as long as the condition is met that all starting points of all branchings belong to the object which the symbol was attached to.

If the symbol plane cannot be moved (e.g. the symbol is attached to a point object), the symbol will remain in its place.

If you need to edit text as part of the object (dimension text or text in designation), select the object, move the cursor away from this object and press `<Shift> +<Enter>`. Make changes in the appearing dialog and then close it by clicking the **OK** button.

You can call the dialog for setting the dimension value by double-clicking the dimension text. Depending on the dimension's type, you can use this dialog to change name of the variable, dimension's value, and other parameters (see Section 2.9.2.2.1 on p. 634).

2.14.3.5.3. Editing Mates

To edit a mate, select it in the Design Tree and use context menu item **Edit**.

Unlike the editing of operations, when editing a mating, the model is not refreshed to the state it had at the time this mating was created.

If necessary, specify other objects for mating. Adjust the mating parameters (such as object orientation or distance between them) using controls on the Property bar.

If the shape of the selected elements and the existing relations and constraints do not conflict with the mating, then the model will attribute in such a way as to satisfy the mating condition. If the mating cannot be rendered with the specified conditions, then the system will mark it as incorrect just after the editing. Sometimes the mating condition may be rendered correctly however making conditions of other matings incorrect. In this case the error will be displayed in these matings.

When editing a mate, you cannot change its type, that is, you cannot turn, for example, an *At Distance* mate into a *Parallel* one.

2.14.3.6. Other techniques of editing

2.14.3.6.1. Editing a model using the Properties window

You can view and change the following properties of selected objects without editing each of them individually:

- ▼ display parameters – color, line style, vertex style, etc.,
- ▼ properties – symbol, name,
- ▼ state — managing fixing, visibility, calculation, editing, projecting objects into the associative drawing,
- ▼ parameters set during object creation (for dimensions, symbols, and so on),
- ▼ the text included into the object contents,
- ▼ the text style, font and paragraph parameters,
- ▼ spelling language attribute.

In order to change object properties, as well as to view the properties window, use the **Properties** window. This window is displayed by calling the **Editor – Properties** command or by clicking the **Properties** button on the Standard bar.

Controls of the **Properties** window and modifying the properties are described in Section 1.4.2.2 on p. 82.

When working with properties in the model documents, keep the following in mind.

- ▼ You can specify objects of the first level – axis and coordinate systems, layout elements, curves and points, sketches, objects of auxiliary geometry, components of the first level of bodies created in the model, faces of the bodies, etc.
- ▼ The list of properties in the window depends on the type of the selected object. For example, clicking the dimension's extension line displays its attributes as a layout element. Clicking the dimension text displays properties of the dimension text.
- ▼ You can set the object's property to **By layer**. In this case, the value of the property inherits the value set for the layer where the object resides. The layer-controlled properties of the objects include:
 - ▼ visibility,
 - ▼ ability to edit,
 - ▼ color,
 - ▼ ability to project into the associative drawing.
- ▼ Values of properties in the **Properties** window are available for editing if this does not conflict other properties. For example, you cannot change the **Color** and **Optical properties parameters**, when the color is set **By source object**, **By source** or **By layer**.
- ▼ The **Visibility** property of an object is not available when all objects of this type are hidden using the **Hide all auxiliary objects** command (see Section 2.14.1.1.2 on p. 781).
- ▼ Changing the **Base designation** property is not available, if automatic sorting of letters in the designation was enabled during creation or editing the base (see Section 2.9.3.3 on p. 658).
- ▼ The **Language** property is available, if designation of a leader is highlighted.

2.14.3.6.2. Editing model

Using End of Model Design Marker

By using the End of Model Design Marker (see Section 2.1.2.6 on p. 112), you can suspend objects from the model. The Marker can also be used for changing the model design sequence.

You will be able to carry out editing using the Marker if Model Tree shows the model design sequence (see Section 2.1.2.1 on p. 106).

Move the Marker so to make it split the Construction Tree into two portions.

You will see that the objects that are below the Marker are displayed in the grey color and are marked with a “lock” icon. These are suspended objects. Information about them remains in the document, however, these objects and their derivatives are not displayed in the model window.

To quickly move the Marker to the end of the Construction Tree, you can use **Rollback Bar to End** command from the Marker’s context menu. This command restores all suspended objects in the model. The model will be rebuild taking into account the restored objects.

Please note the following features of suspended deletion and restoration of objects in the model.

- ▼ Object restoration (by moving the Marker to bottom) is actually re-creation of these objects. In particular, this has the following consequences.
 - ▼ If any changes were made to the properties of faces of a feature prior to its suspended deletion, then these changes will be lost after the feature is restored, because the feature will be re-created with default face properties.
 - ▼ If the model had objects derived from instances of a component array (a chamfer was constructed on the instance edge, a sketch was constructed on the face, an auxiliary axis was based on the vertex, etc.) when the component array was suspended, then these objects will be marked as failing objects after restoring the array. The cause will be that the previous array instances (which the objects were based on) are no longer in the model: they have been replaced by new ones. The failing objects should either be deleted and then re-created, or edited by specifying new source objects for them.
- ▼ If the Marker is moved above the component array while working with the model, a delete objects dialog will appear listing all components-array instances to be deleted and the matings (if any) which they are involved in.
 - ▼ To finalize moving the Marker, confirm the deletion by clicking **OK** in the dialog. Please note that mating information will be deleted from the model, i.e. you will not be able to recover the mates just by moving the Marker. Array instances will be suspended and can be restored.
 - ▼ To cancel moving the Marker, decline the deletion by clicking **Cancel** in the dialog.

While working with a model, you are not in any way limited to move the End of construction marker. The icons of the newly created elements will be positioned in the Construction Tree before the Rollback Bar.

This property of the End of Model Design (rollback) marker, and that the excluded from calculations elements are not displayed on the screen and cannot be used in constructions is convenient to use when modifying the order of building the model.

For example, to edit a part obtained by the operation of mirror copying, you need to make changes to that its half, which is the original, by positioning them before the mirror copy operation. However, firstly, both halves of the part will look completely identical. Secondly, while editing, you can accidentally use the objects of the part's half that was created by copying, which will inevitably lead to an error. In such cases, it could be helpful to move the End of Model Design (rollback) marker so that the mirror copy operation and all the following ones were excluded from calculations. Only the original half of the part will be displayed. You can edit it as desired. After including the copy operation into the calculations, the second half of the part will also include the introduced changes.

If the model elements located below the End of Model Design (rollback) marker are not needed for further construction and do not have to be in the model, you can simultaneously delete all those objects. To do this, use the command **Delete Elements below Rollback Bar** (the Marker) from the context menu accessed on the Marker.

Upon calling the command, a warning dialog will appear. It will list model elements to be deleted. You can cancel or confirm the deletion.

2.14.3.6.3. Changing the sequence of operations

A convenient (though rarely used) technique of editing a model is “dragging” operations in the Design Tree. In this way, you can quickly change the design sequence.

The design sequence can be modified if the model design sequence is displayed in the Model Tree (see Section 2.1.2.1 on p. 106).

To move an operation in the Design Tree, hover the cursor over its icon, left-click it and, while holding it, drag the cursor to the desired location in the Design Tree. While doing so, the cursor appears as an arrow indicating the operation's position.

When the desired operation location is reached, release the mouse button. The operation's icon is placed in the Design Tree at the specified position and is marked by a red “check mark”. This means the change in the creation order has not been yet propagated to the model — the image in the window remains the same.

To rebuild the model, apply the following command: **View— Rebuild**.

The operations are moved with respect to their hierarchy. An operation cannot be moved about the source (parent) one or below a dependent object in the Design Tree.

2.14.3.7. Model rebuilding

Rebuilding a model can be considered as making the model up-to-date. When you rebuild a model, the shape and position of its objects are recalculated, so that the model appearance on the screen can change.

If MP parameters are recalculated during rebuilding (see Section 9.1.11.15 on p. 1738), then the mass value and coordinates of the center of gravity are also updated within the model.

Rebuilding is required when the model contains conflicts, i.e. its geometry does not match the original data, such as history of builds, operation parameter values, matings, etc. The conflicting objects are marked with a red “check mark” in the Model Tree. When at least one object requires rebuilding, the model's header in the Tree is also marked with the red “check mark”, so that you will see it even when the Tree is fully collapsed.

To rebuild the model, choose **View — Rebuild** or press <F5>. The button to call this command is located on the panel **View**.

The conflict in the model can occur when you make changes in one of the following objects:

- ▼ The value of a variable corresponding to the operation parameter was changed in the Variables window. The resulting object will not change in the model window, but will be marked with the red “check mark” in the Design Tree. After rebuilding the object in the model window will be updated with the new value of the parameter and the red “check mark” will be removed.
- ▼ You've changed the sequence of the operations by dragging them with the mouse in the Design Tree. All operations you've moved are marked with the red “check mark” in the Tree, but the model in the window does not change. After rebuilding the “check marks” are removed and the appearance of the model may either change or stay as it is depending on the set of operations. For example, if you drag a trimming operation in between the plains outside these plains, then the body will be trimmed entirely. However if you swap two independent operations in the Tree, the model will likely stay unchanged.
- ▼ Two components are mated in such a way that a face of the first component touches a cylinder surface of another one. Then you've edited the second component, so that its cylinder face used in this mating turned into a conic one. The new shape of the component will appear in the model window, but the position of the first components will not change. The icon of the edited component is marked with the red “check mark” in the Design Tree. After rebuilding the “check mark” disappears and the first component is positioned in such a way that the existing mating (touching of the surfaces) remains consistent.
- ▼ The model contains an auxiliary axis going through the vertices of the two components. Then the position of one of the components was changed, e.g. due to mating with another one. The icon of the component is marked with the red “check mark” in the Design Tree, and the auxiliary axis does not change its position. After rebuilding the red “check mark” disappears, and the position of the axis is changed in such a way that it goes through the specified vertices.

In some cases, the system can automatically determine that the model needs rebuilding and notify you about it. For example, this request may occur when you load a model in which one of the components does not match the data stored in this model. This may be caused either by changes in the component's geometry or changes in its properties, such as name, designation, material, etc.

The conflicting components are displayed in the request window.

If you want to rebuild the model, click the **Yes** button of the dialog.

If a model consists of a large number of components, rebuilding it can take a significant time. Therefore, if you need to edit several components of a complex model, it would be rational to

rebuild it just once — after making all changes (rather than each time after editing an individual component).

To postpone rebuilding the model, click the **No** button of the dialog. The model rebuild request will disappear, and the icons of the objects to be rebuilt will be marked with the red “check mark” in the Design Tree.

You can also rebuild the model in any time by choosing **View — Rebuild**.

After rebuild some models may display errors, such as exclamation marks in red circles, which mean that the objects are built incorrectly. For example, suppose, a model cut element was extruded up to a face of some part. Then this part was displaced so that the mentioned face could not further constrain the extrusion element (i.e., the element sketch is either partially projected on this face or it cannot be projected on it at all). The element cutting become impossible, and after the model rebuilding this operation is marked in the Design Tree as wrong.

2.14.3.8. Deleting an object

Any object (a geometry-producing feature, a sketch, an auxiliary axis or plane, assembly component, a mating, etc.) can be deleted from the model. You can do this simply by selecting them in the Construction Tree and using context menu item **Delete** or pressing <Delete> key.

If other objects reference the deleted object or the deleted object is involved in mating, then a warning dialog will be displayed. It displays the hierarchical list (see Fig. 2.14.4) where:

- ▼ the first level – icon of a model or variant whose objects are being deleted;
- ▼ the second level – **objects that are being deleted**;
- ▼ the third and the following levels – model's objects related to objects being deleted (linked objects also include mates with participation of objects being deleted); linked objects are **deleted together with their source objects**.

You can cancel or confirm the deletion.

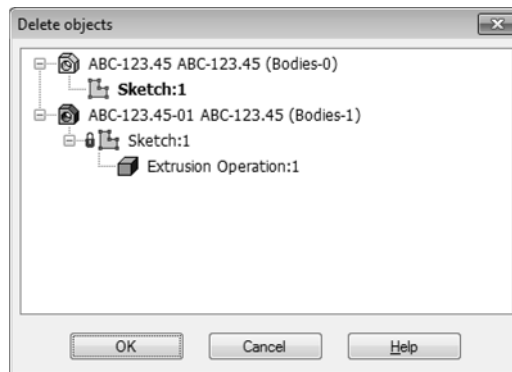

Fig. 2.14.4. Items Deletion dialog

2.14.4. Restructuring a model

Editing model structure means change of the components hierarchy. In most cases, a set of files comprising the model is changed as a result of assembly structure editing.

The following options of model structure editing are available:

- ▼ part– subassembly transformation and subassembly– part transformation (see Section 2.14.4.1),
- ▼ integration of components into subassembly and explosion of subassembly (see Sections 2.14.4.2 on p. 799 and 2.14.4.3 on p. 799),
- ▼ copying and moving components (see Section 2.14.4.4 on p. 800),
- ▼ splitting model objects into parts (see Section 2.11.2.3 on p. 689).

As a result of structure editing, certain matings laid upon the components participating in this procedure can be removed from the model. Therefore, it is recommended to set matings after complete specification of the model structure.

2.14.4.1. Part-to-subassembly and subassembly-to-part transformations

- ▼ Part-to-subassembly transformation means saving the part inserted into the current model in the file of a new assembly (*.a3d).
- ▼ Subassembly-to-part transformation is saving of the subassembly inserted into the current model in the file of a new part (*.m3d).

You may need part – subassembly and subassembly –part transformations when designing assembly 'top down'. For example, at the initial stages of a gearbox design, it was planned that its cover would be welded. Correspondingly, the *Cover* was inserted into the gearbox model as a subassembly. It turned out later that it would be wiser to manufacture a cast cover, i.e., the component should be a part and not a subassembly. To quickly edit the gearbox model, use subassembly-part transformation.

The transformation is only applicable for the components at the first level of the model structure, i.e., for those inserted directly into the current model. When you need to transform the components built into a subassembly, you should enter the editing mode of this subassembly.

To perform the transformation, select the required component (a part or an assembly) in the Design Tree and call the **Save As...** command from the context menu or go to **Editor — Edit component**.

Windows-standard File Save dialog will be displayed. In the **File Type** list select the following:

- ▼ to convert a part into a sub-assembly— the **KOMPAS-assemblies (*.a3d)** line,
- ▼ to convert a sub-assembly into a part — the **KOMPAS-parts (*.m3d)** line,

Specify both folder and file name for saving, then click the **Save** button. The dialog will close.

The saved component replaces the previous one in the current model. The previous component will be removed from the model, but its file on the disk will not be changed.

To save the transformations in the current model, choose **File— Save** command.

The subassembly – part transformation has the following peculiarities.

- ▼ All objects created in the subassembly are saved in the part file: bodies, sketches, auxiliary objects, etc. Also, the following objects created in the components of a subassembly are copied to the part:

- ▼ bodies, surfaces, curves – as the respective objects without history,
- ▼ points, including control and connection ones – as points constructed based on coordinates.
- ▼ The following errors may occur when transforming a subassembly into a part:
 - ▼ errors related to missing reference objects, when the components of the transformed subassembly were used for building other objects in the model (including those located in the same subassembly),
 - ▼ mating errors – when components of the transformed subassembly were used in matings.

The **Save as...** command can be used to save the component under a different name and to automatically insert the renamed component instead of the previous one into the current model.

2.14.4.2. Combining components into subassembly

You can combine several components of the current model into a subassembly.

It is possible to combine only components of the first level, i.e. inserted directly into the current model, not in any of its sub-assemblies.

The product of the combination is a new assembly file (*.a3d) containing the components of the current model selected for combining. The new assembly will be inserted in the current model as a subassembly, and components it will be made of will be deleted from the model. Files of these components remain unchanged on the disk.

The absolute coordinate system of the new subassembly will match the absolute coordinate system of the current model.

To combine components into a subassembly, select them in the Design Tree and call the context menu command **Combine into subassembly**. In the displayed standard file save dialog box specify both folder and assembly file name for saving, then click the **Save** button. The dialog will close.

To save the transformations in the current model, choose **File— Save** command.

It is impossible to combine into a sub-assembly the components being instances or source objects of an array.

2.14.4.3. Exploding subassembly

You can explode a subassembly of the current model into individual components.

It is possible to explode only the first level subassemblies, i.e. inserted directly into the current model, not in any of its subassemblies.

As a result of subassembly explosion, all its components are transferred into the current model. Their position is not changed. The other objects of the subassembly— surfaces, curves etc., as well as operations made in the sub-assembly (bevels, openings etc.) — are not transferred to the current model.

Destroyed sub-assembly is deleted from the model. File of sub-assembly on the disk will not change.

To explode a subassembly, select it in the Design Tree and call the **Explode component** command from the context menu or from the menu **Editor — Edit component**.

Sub-assemblies being inside the destroyed sub-assembly are not destroyed. If necessary, you can apply the explode command to them.

It is impossible to explode the sub-assembly being an source array object.

2.14.4.4. Moving and copying components

You can move and copy components:

- ▼ from one to another subassembly of the current model,
- ▼ from the current model to any of its subassemblies, and visa versa.

Moving is performed in the Design Tree by “dragging” a component with the mouse to the sub-assembly or model icon (or to the icon of the *Components* section inside the subassembly or model).

Copying of a component is performed in a similar way, but with <Ctrl> button pressed; in doing so, the “+” sign is displayed next to the cursor.

When “dragging” a component over the icon of an object to which it cannot be moved or copied, a warning sign is displayed instead of the cursor.

After the component has been moved, its position in the model is not changed.

As a result of copying, overlaying components are obtained. To change the position of the source component or the copy component, use the move and rotate commands (see Sections 2.11.3.1 on p. 699 and 2.11.3.2 on p. 699).

You can copy and move components not only in the Design Tree but in the Model window as well. In this case, you can randomly set the position of the component in the model's coordinate system. However, the position of the component in the model structure is limited to the first level, i.e., the moved or copied component is inserted directly into the current model.

To move a component in the Model window, do the following.

1. Select the component in the Design Tree or in the Model window.
2. In the model window, place the cursor on the component.
3. Click the left mouse button and press the <Alt> key.
4. Move the mouse. The ghost of the component will move together with the cursor in the Model window.
5. When the ghost reaches the desired position, release the mouse button and then the <Alt> key.

Copying of a component is performed in a similar way, but with the <Ctrl> button pressed; in doing so, the «+» sign is displayed next to the cursor. In addition, for copying you can select not only one but multiple components as well.

You can also copy components using their icons in the Design Tree. For this, do the following.

1. Select the component(s) in the Design Tree.
2. press the <Ctrl> key and “drag” the component from the Design Tree into the Model window. Release the mouse button.
3. Move the mouse in the Model window. The ghost of the component will move along with the cursor.
4. As soon as the ghost reaches the required position, click the left mouse button and release the <Ctrl> key.

No matter what method is used to move or copy the component, this operation will lead either to creation or removal of a reference to the component file in the model file:

- ▼ when the component is moved, a reference to it is removed from one file (for example, subassembly file) and added to another file (for example, assembly file),
- ▼ when the component is copied, a reference to it is added into model or subassembly file.

You cannot move the component that is a source array object or instance.

2.14.5. Saving an assembly as a part and a part as an assembly

You can save the current part (*.m3d) in the new assembly file (*.a3d), i.e. transform the part into an assembly and vice versa, as well as save the current assembly (*.a3d) in the new part file (*.m3d), i.e. transform an assembly into a part.

To perform the transformation, select **File — Save as...**

Windows-standard File Save dialog will be displayed. In the **File Type** list select the following:

- ▼ to transform part into assembly— line **KOMPAS-assemblies (*.a3d)**,
- ▼ to transform assembly into part— line **KOMPAS-parts(*.m3d)**,

Specify both folder and file name for saving, then click the **Save** button.

Upon the completion of the transformation, the source part or assembly is still displayed on the screen. To download the model which is the product of transformation, use the **File-Open** command.

When transforming an assembly into a part, keep the following in mind.

- ▼ All objects created in the assembly are saved in the part file: bodies, sketches, auxiliary objects, etc. Also, the following objects created in the components of an assembly are copied to the part:
 - ▼ bodies, surfaces, curves — without history,
 - ▼ points, including the reference points and connection points — with coordinates.
- ▼ A resulting part may contain errors due to missing reference objects, if its components (such as axis going through the zero points of the components) were used for building the assembly's components.

If you want to convert a child model in order to replace it, choose **Save as....** (see Section 2.14.4.1 on p. 798).

2.14.6. MP and model's hatch parameters

The mass properties of models may be calculated or set manually.

- ▼ In the first case, the model's MCC are calculated based on MCC of its elements: bodies and components.
- ▼ In the second case only the center of gravity coordinates are calculated (the model mass is entered by the user) or no calculations are performed (both the model mass and center of gravity coordinates are entered by the user).

The model mass and center of gravity coordinates (either calculated or entered manually) are saved in its file. During the insertion of a model into another model as a component, these parameters are often sent to a model and used for calculating its mass properties.

If necessary, you may set the MPs for components which differ from their original ones. These parameters will be stored and used in the model which contains components.

To speed up MP calculations for a model, it is recommended to save all its components files in KOMPAS-3D version 10 or later.

The general methods of setting the MP parameters are covered in Section 2.14.6.1 whereas the procedure for setting MPs of bodies, components and models is given in Sections 2.14.6.2–2.14.6.4. Section 2.14.6.5 is dedicated to settings of a system and document related to the models' MP; section 2.14.6.6 describes setting model's hatch parameters.

2.14.6.1. General Methods of Setting MP Parameters

The mass properties of an object (body, component or model) are managed using the controls on **MP parameters** of the Properties bar.

The body volume is always calculated by the system automatically. The controls on **MP Parameters** tab may be used to set:

- ▼ material and density of material (see Section 2.14.6.1.1) to calculate the mass the center of gravity coordinates,
- ▼ arbitrary values of mass and center of gravity coordinates (see Section 2.14.6.1.2).

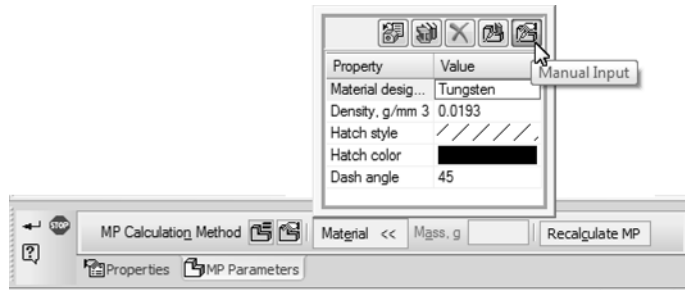

The **MP parameters** tab also contains **Recalculate MP** button (Fig. 2.14.5). Clicking this button initiates calculation of assembly MPs using the current values of parameters. The Message window with the calculation results pops up when calculation is finished

The Informational window contains the summary of calculation (mass, volume, area, center of mass coordinates of the body or the model). To obtain the inertia properties of the model (moments of inertia and direction of inertia main axes), use **Model Mass Properties** command (see Section 2.15.2.4 on p. 817).

2.14.6.1.1. Material and Material Density

Materials are selected using **Material** panel (Fig. 2.14.5).

Fig. 2.14.5. MP calculation by density; **Material** panel

The table displays properties of a model's material: name of the current material, density and hatch parameters that are used for displaying the material on cut/section in the drawing.

Select from List of Materials button allows selecting material from the density reference file (file ...IASCONKOMPAS-3D V...Sys\Graphic.dns; the values of the material's parameters contained therein may be edited by the user) whereas **Select from Reference of Materials** button enables selection from the Reference of Materials and Assortments.

Once the material is selected, values in **Material designation** and **Density** cells are filled in automatically.

To set density click the **Calculation by Density** radio button in the **MCC Calculation Mode** group on the Property Bar (Fig. 2.14.5). You can use the reference density value for calculation, i.e. the value which corresponds to the selected material or an arbitrary value.

▼ If the **Select from reference** switch is enabled, the reference density value is used in the calculation (the default option). The material density value will be imported from the density reference file or the Reference of Materials and Assortments and displayed in the **Density** field.

▼ To set an arbitrary density value, click **Manual Entry** radio button and enter the required value in the **Density** field.

Refer to Section 2.14.6.6 on p. 809 for more information about models' hatch settings.

2.14.6.1.2. Mass and Center of Gravity Coordinates

To set the mass of a model, enable the **Calculation by Mass** switch (Fig. 2.14.6). Enter the mass value into the **Mass** field.

If necessary, you may also define the coordinates for the center of gravity. For that, enable the **CG** option and enter the coordinates into the table on the **Center of Gravity** bar.

Fig. 2.14.6. MP calculation by density, **Center of gravity** panel

2.14.6.2. Body MP Parameters Calculation

To setup the body MCC calculation parameters select it in the Construction Tree and call **Body Properties** command from the context menu (Fig. 2.14.7).

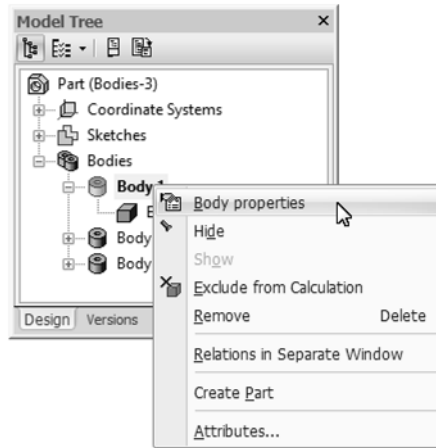

Fig. 2.14.7. Calling the **Body Properties** command

The body icons and names are shown on the Tree if the model structure is enabled (see Section 2.1.2.2 on p. 106).

Enable **MP Parameters** tab on the Properties panel (Fig.2.14.8).

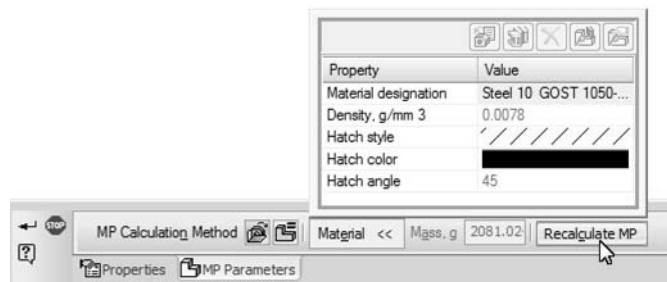

Fig. 2.14.8. Setting MP Parameters for a Body

The following MP parameter options are available for bodies.

- ▼ Using the MP parameters defined in the properties of the source model – i.e. the part of assembly on which the body being adjusted is built. To enable using the MP parameters of the source click **From Source** radio button in **MP Calculation Method** group. After this, **Material** and **Mass** controls will become unavailable.
 - ▼ Setting Body Material and Material Density (see Section 2.14.6.1.1).
- After completing MP Parameters setting click **Create Object** button on the special control panel.

2.14.6.3. Parameters for calculating components MP

The MP parameters may be set for any element in a model: a part (including local ones), sub-assembly, or a library component. While doing so the component file remains unchanged. You may also set up the MP parameters for components which constitute the array instances.

To set component MP parameters select the component in the Construction Tree and call **Component Properties** command from the context menu. Activate **MP Parameters** tab on the Properties panel.

The following MP parameter options are available for components:

- ▼ Using the MP parameters stored in the component source file. To enable using the source MP parameters select **From Source** radio button in **MP Calculation Method** tab. After this, **Material** and **Mass** controls will become unavailable.
- ▼ Entering the component mass and, if necessary, the center of gravity coordinates (see Section 2.14.6.1.2 on p. 803) (Fig.2.14.9). Please note that the component center of gravity coordinates must be set in the coordinate system.

If the component's mass center coordinates are not set by the user, they are calculated based on densities and volumes of bodies and components included in the component.

Fig. 2.14.9. Setting component mass and center of gravity

- ▼ Setting material and density for the bodies in a component (see Section 2.14.6.1.1) (Fig. 2.14.10).). The specified density will be applied to all the part bodies which do not have their unique density settings.

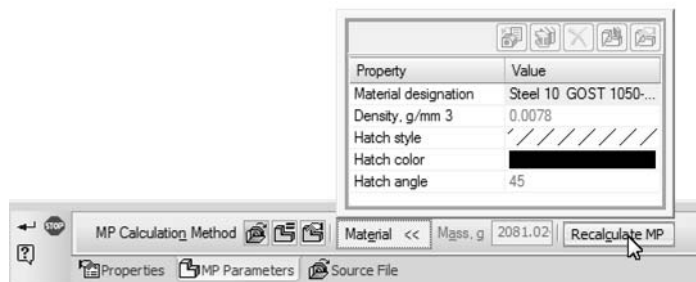

Fig. 2.14.10. Manual setting of component-part density

After finishing setting component parameters for MP calculation, click **Create Object** button.

In the Property Editor, you can view properties of materials of all bodies and components. You can also change their values for components of the first level and recalculate the mass of the model (see Section 5.1.4.2 on p. 1389).

Example of manual setting of component MP

Let us assume that a hypothetical, i.e., without drawing particular parts and elements, model of an electric motor is embedded into the assembly, and its mass and center of gravity coordinates are different from the standard ones. However, to obtain the correct MP of the assembly, it is necessary to use the standard MP parameters of the electric motor.

This can be done in two ways.

Method 1. Entering and storing the standard MP parameters in the electric motor model. For this, do the following.

1. Open the electric motor model, select the first element of the Design Tree and call **Model Properties** command from the context menu.
2. Go over to **MP Parameters** tab on the Property panel and click **Calculation by Mass** radio button in **MP Calculation Method** group.
3. Enter the standard mass value of the electric motor in the **Mass** field.
4. Activate **CG** option and enter the standard center of gravity coordinates of the electric motor into the table on **Centre of Gravity** panel.
5. Click **Create Object** button.
6. Save the model.

The specified MP parameters will be saved in the model and transferred to the assembly. Editing the model — adding or removing material — does not affect the mass value and center of gravity coordinates entered manually.

Method 2. Entering and storing the standard MP parameters in the electric motor assembly. For this, do the following.

1. Open the assembly containing the electric motor model as a component.
2. Select *Electric Motor* component in the Design Tree of the assembly and call **Component Properties** command from the context menu.
3. Go over to **MP Parameters** table on the Property panel and select **Calculation by Mass** radio button in **MP Calculation Method** group.
4. Enter the standard mass value of the electric motor in the **Mass** field.
5. Activate **CG** option and enter the standard center of gravity coordinates of the electric motor into the table on **Centre of Gravity** panel. The values of coordinates be specified in the component system of coordinates (not those of the assembly).
6. Click **Create Object** button.
7. Save the assembly.

The specified MP parameters of the component will be saved in the assembly and will be used for calculating its mass properties. There will be no changes in the electric motor model — the calculated mass values and centre of gravity coordinates will be stored unchanged.

Peculiarities of calculating model's MP parameters after editing

- ▼ The mass *set for a component manually* (in a model or in a source file) is considered fixed until the component or any of its parts is present in the model. If the model is edited so that the component's entire body disappears, it will be considered to have zero mass. For example, after creating a hole in a model going through a component, the mass of this component will not change; once the component is deleted by means of cutting by plane, the mass of the component will be zeroed.
- ▼ If a boolean operation is applied to bodies of two components in a model, then the mass values of these bodies will no longer be taken into account when calculating the model's MP parameters. Instead, mass of the body resulting from the boolean operation will be taken into account. If necessary, parameters of MCC calculation for this body can be changed (see Section 2.14.6.2 on p. 804).

2.14.6.4. Parameters for MP calculation of part and assembly

To set up the parameters for model (part or assembly) MP calculation select it in the Model Tree and call **Properties of a Model** command (Fig.2.14.11).

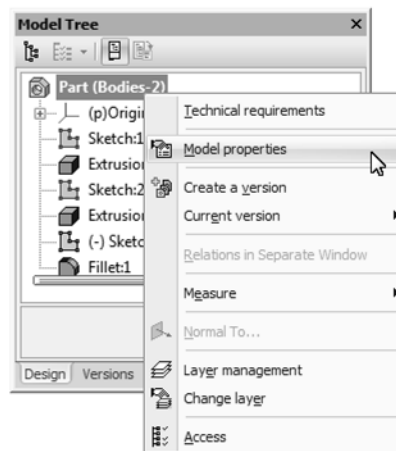

Fig. 2.14.11. Calling the **Properties of a Model** command

Activate **MP Parameters** tab on the Properties panel.

The following MP parameter settings are available for models:

- ▼ Setting material and density (see Section 2.14.6.1.1 on p. 802) (Fig.2.14.12). The specified density will be applied to all the model bodies created directly in the model and which do not have their unique density settings. The model mass is defined as the combined mass of its bodies and components.

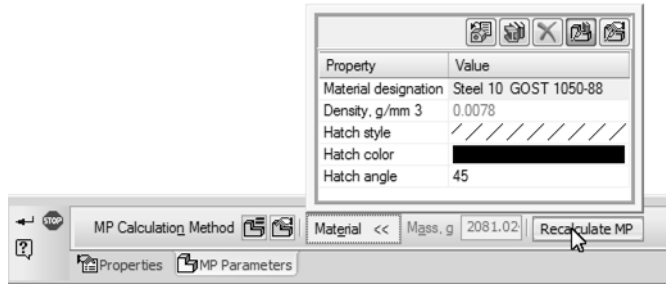

Fig. 2.14.12. Setting model density

- ▼ Setting the total model mass and, if necessary, the center of gravity coordinates (see Section 2.14.6.1.2 on p. 803) (Fig. 2.14.13). If the model's mass center coordinates are not set by the user, they are calculated based on parameters of bodies and components included in it. The bodies with no unique density settings are applied the reference value corresponding to the model material.

Fig. 2.14.13. Setting component mass and center of gravity

After completing MP Parameters setting click **Create Object** button on the special control panel.

The values of model mass and center of gravity coordinates calculated or entered manually will be recorded to the model file.

In the Property Editor, you can view properties of materials of all bodies and components in the model. You can also change their values (note that you can change the component's properties only for the components at the first level in the hierarchy) and recalculate the mass of the model (see Section 5.1.4.2 on p. 1389).

2.14.6.5. MP Setup

The following settings related to mass properties of models are available in KOMPAS-3D:

- ▼ Automatic MP calculation setup (see Section 9.1.11.15 on p. 1738),
- ▼ MP calculation precision setup (see Section 9.2.7.4.10 on p. 1854),
- ▼ MP measurement unit selection (see Section 9.2.7.4.15 on p. 1858),
- ▼ setup of the material, material's density and hatch parameters of a part that are used by default in a new document (see Section 9.2.7.4.1 on p. 1843).

2.14.6.6. Hatch parameters of a model

Hatch parameters of a model can be set up using one of the following commands: **Model properties**, **Body properties**, or **Component properties**.

You can set up hatch parameters of a model's material (style, color, and hatch angle) in the **Material** bar of the **MCC Parameters** tab. These parameters are saved in the model and used when it is displayed on cut/section in the drawing's associative view.

You can set up hatch parameters, if MCC parameters are calculated by density or by mass. If MCC parameters are specified based on a source (available for components and bodies), hatch parameters will also be specified on the source's basis.

In order to specify the hatch style, click the cell of the **Hatch Style** value. A list will be displayed from which you can choose the hatch style, including a custom one (Fig. 2.14.14).

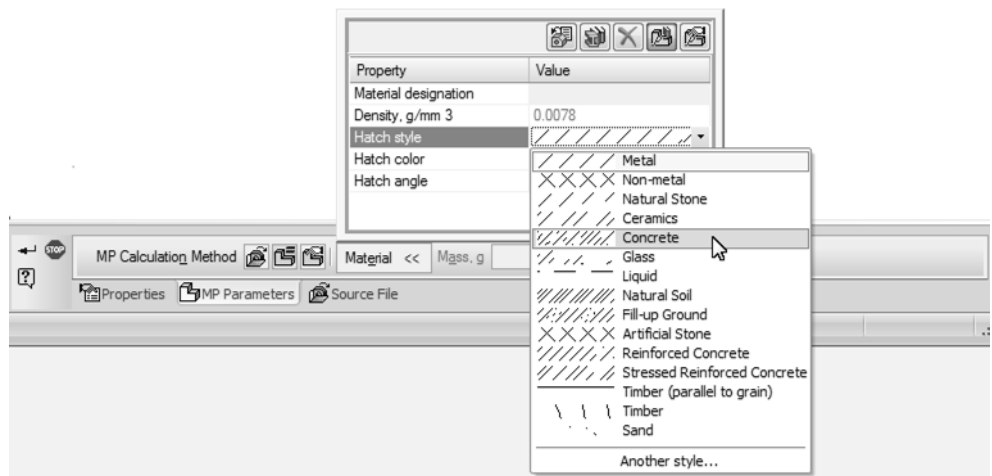

Fig. 2.14.14. Selecting the hatch style

See Section 10.1.1.2.2 on p. 1912 for more information about creating custom hatch styles and saving them in the library.

Hatch style is automatically applied to model if material is selected from the file of densities by clicking the **Select material from list** button (see Section 2.14.6.1.1 on p. 802). This is due to the fact that the file of densities contains information about relation of a hatch style to a certain material. See Section 9.5.5.2 on p. 1897 for more information about preparation of the reference file of densities.

In order to change the hatch color or set its angle, click one of the following cells, respectively: **Hatch color** or **Hatch angle**. The color selection dialog or the list of angle values will be displayed. If necessary, enter the angle value manually.

The specified inclination angle will be applied to hatch on the drawing, if the chosen style supports angle modification.

You can change hatch parameters when setting up material properties to components and bodies in the Property Editor (see Section 5.1.4.2 on p. 1389).

After completing hatch parameters setup click **Create Object** button on the special control panel.

2.15. Service Functions

2.15.1. Model diagnostics

2.15.1.1. Error Warnings

If such model editing was done that invalidated some of its objects, considering the hierarchy and/or parametric relations, then KOMPAS-3D will output the respective diagnostics message. It indicates the specific reason for the conflict or loss of the relation between the model components (for example, “*The feature lost the base object*”, “*The base surface is changed*”, “*Empty Sketch*”, “*Self-Intersection of Contour*”, etc.).

At the same time, the model is not rebuilt, but stays in the state in which it was before calling the editing command. An error flag appears in the Design Tree next to the icons of the objects which became nonexistent after the editing.

If there is an error in at least one model object (element, component, match, etc.), an error flag appears not only next to the icon of this object, but also next to the icon of the model (element or assembly). So, an error existing in the model can be noticed even if the Design Tree is minimized.

To find out the reason for the occurred error, select the erroneous object in the Design Tree and call the **What is wrong?** command from the context menu.

A dialog in which the errors are listed, that occurred during this object rebuild will be displayed.

Errors are displayed in the dialog as a structured list. Description of each error is located at the level next to the name of the failing object.

When browsing through all model errors, its failing components (geometry-producing features, auxiliary axes and planes, copies, chamfers, shells, components, mates, etc.) will appear in the list at the level below the model name.

The help system contains recommendations on possible error-fixing techniques.

To get explanation for the specific error and general recommendations on fixing it, select the error description in the dialog and click the **Help** button. Read the displayed page of the Help system, think, which of the described cases is most similar to the error in your model, and remember recommendations on its fixing.

To fix an error, edit a feature, sketch or mate, in which it occurred, or the source elements according to the Help system recommendations. Often, to fix an error, it is enough just to edit the failing model again, reverting to the old object parameters.

If a model has several errors, fix those in the order in which the failing elements appear in the Design Tree.

Some errors make it impossible to maintain elements, continue construction and editing a part. For example, after editing a contour, reference vertices for making construction axes and planes disappeared in the sketch, and a derivative element cannot be rebuilt (the model “fell apart”, it cannot be further used before fixing the error).

Other errors are not so critical and do not prevent from working with the model further. For example, when translating a sketch to another face, the parametric relations of the sketch graphical objects were lost. In this case, graphical objects are not rebuilt in the sketch, the contour formed by them stays the same, and the element based on it is not destroyed, thus allowing to maintain the dependent elements.

In any case, it is recommended to fix an error right after its occurrence.

2.15.1.2. Model Rebuilding Warnings

Upon assembly editing (moving the components, changing the value of the variables, etc.), the links between the model components may be broken. For example, auxiliary elements may remain after their reference objects have been moved. The components that caused such conflicts are marked with red “ticks” in the Design Tree.

To resolve the conflicts, you will need to rebuild and/or move all objects so that their shapes, parameters and positions match the positions of reference objects and comply with the imposed matings. You do this using **View — Rebuild Model** command. For details about links, see Section 2.14.3.7 on p. 795.

Sometimes, the warnings may be displayed after rebuilding a model (exclamation marks in red circles).

2.15.2. Measurements

While working with a model, you may need to find a distance or an angle between the vertices, edges or faces, a curve length, a face area.

KOMPAS-3D supports measurements of various geometrical parameters, as well as calculation of mass-centering properties of a model (volume, mass, center of gravity coordinates, axial and centrifugal moments of inertia, directions of the principal axes of inertia).

Geometrical parameter measurement results can be saved in the model as a variable values.

Measurement commands are grouped in menu **Service**, and buttons to call commands— in panel **Measurements and diagnostics (3D)** (Fig. 2.15.1).

Fig. 2.15.1. **Measurements and Diagnostics (3D)** Toolbar

After call of any of the measurement commands, the Properties bar displays the **Measurement** tab. It contains elements allowing to customize measurement process parameters. These elements are presented in Table 2.15.1.

Tab. 2.15.1. Control elements of measurement parameters

Element	Description
Decimal Places	A list that manages precision of presentation of calculation results. Minimal decimal place is 0, and maximum is 10.
Length Units	The list allows selection of length units: millimeters, centimeters, meters.
Angular Units	The list allowing selection of angle units: degrees, radians. Only for the Distance and Angle command.
Mass Units	The list allows selection of mass units: grams, kilograms. Only for command MP Models .
Brief	Options that allows to get brief or full measurement results. Only for commands Distance and Angle , Model Mass Properties , Deviation of Surfaces .

The buttons to call the **Check for Intersections** and **Object Info** commands are located on the **Measurements and diagnostics (3D)** bar. More information about working with them is provided in Chapters 2.15.3 and 2.15.6, respectively.

You can set up precision to calculate MP and areas of faces in the model. This setup is described in Section 9.2.7.4.10 on p. 1854.

2.15.2.1. Distance and Angle

You can calculate the distance and, if possible, the angle between two specified objects. Such objects can be coordinate and auxiliary axes and planes, faces, edges, vertices, 3D curves and points. Can be selected in any combination (for example, a plane and a vertex, an edge and an axis, two faces).

To calculate the distance and angle between two objects, enable the **Distance and Angle** command.

Click on the first object in the Model window. The selected object is highlighted.

Move cursor to the 2nd object.

The Information window will be displaying the distance between them (if it is not zero) and the angle value between them (if objects are neither parallel nor perpendicular). The measurement results will appear near the cursor.

If objects are intersected or parallel or perpendicular, then the respective message appears near the cursor.

The displayed measurement result depends on types of the specified objects and their relative positions.

Description of results is given in Table 2.15.2.

Left click on the 2nd object to enter measurement results to the Information window.

Window management and its menu commands are described in Section 3.8.1.2.

Objects can be selected before calling the command. After the command is called, the objects are highlighted and the following items appear on the screen: Information window with measurement results, ghosts of all measured distances and rotation axes (if the rotation surface is specified).

Tab. 2.15.2. Measurement Results

Value Designation	Measurement results description
L	Distance between objects. Is measured when it's possible to uniquely determine the distance between objects, e.g. between two vertices. Also the L distance is measured if one of the objects is the finite one (face, edge, curve), and the second object is and infinite one (auxiliary, coordinate axis or plane). In this case the result of the L measurement is the shortest distance between the objects.
L (min), L (max)*	The minimum and maximum distance between objects. Is measured between the points of two objects that are the most proximate L (min) and the most distant L(max) from each other. If the objects intersect each other the L (min) value does not appear on the screen. The L (min) and L (max) measurement is made in case when both objects are finite. One of the objects can be pointwise.
L (norm)	Distance between parallel planes. Is measured when the specified objects are situated in parallel planes.
A	Angle depending on the specified objects type: <ul style="list-style-type: none"> ▼ for the rectilinear objects— the angle between crossing or intersecting straights containing these objects, ▼ for a rectilinear object and a plain object— angle between the rectilinear object and its projection on the plain object, ▼ for two plain objects— angle between the planes of the objects, ▼ for a rectilinear object and a rotary surface— angle between the object and the axis of rotary surface, ▼ for a plain object and a rotary surface— angle between the plane of the object and the axis of rotary surface; ▼ for two rotary surfaces— angle between the axes of rotation.
Complement Angle*	An angle which completes the measured angle A to 180° or 360°.
Distance to the axis	Distance from the point to the axis of a rotary surface. Is measured if one of specified objects is a rotary surface.

Tab. 2.15.2. Measurement Results

Value Designation	Measurement results description
Distance between axes	Distance between the axes of rotary surfaces. Is measured if both specified objects are the rotary surfaces.
In projections on the absolute coordinate system axis*	dx, dy, dz — distance projections (L , L(min) , L(max) , L(norm) , Distance to the axis or Distance between axes) in millimeters on the axis of the absolute coordinate system X, Y, Z.

* This parameter is calculated if option **Brief** is disabled on the Properties bar.

To obtain additional measurement results, deactivate the **Brief** option on the Property bar and repeat object selection.

Remember Status button on the Special Control Bar allows to remember first selected object. For example, if you need to measure distance and angle between one object and several others, click the **Remember Status** button after first object selection and then specify other objects.

2.15.2.1.1. Measurement object

When using commands for measuring distance, angle, face area or edge length, you can create **measurement object**. Meanwhile, information variables with values similar to the measurement results and related to the object are automatically generated in the model. For details about informational variable see Section 7.1.1.2.1 on p. 1570.

To create measurement object, specify object (objects) by clicking the mouse in the model window and then click the **Create Measurement** button on the Property bar.

Measurement object corresponding to the last performed measurement appears in the Design Tree and in the Variables Window.

When selecting measurements in the Design Tree, this measurement object (objects) are highlighted in the model window.

When using the **Measure Distance and Angle** command, depending on the **Brief** option status, a measurement object with full or shortened set of variables may be obtained.

The measurement object cannot be edited— it can only be deleted from the model or exclude from calculations.

Each measurement preserves the links with its objects, i.e. once you make changes which influence the measurement results in the model, a variable matching this measurement is updated. If you exclude the measurement object from the calculation, a new value of this variable will be calculated once you include this object in the calculation.

In some cases, editing a model may cause degeneration of the measurement object. For example, when two points are overlapped and have zero distance. In this case, the measurement object is marked as corrupted both in the Design Tree and the Variables window.

If you remove an object used in measurement, then the measurement object is also removed.

2.15.2.2. Edge Length

To calculate the 3D curve length or the part face perimeter, enable the **Edge Length** command.

To measure an object length, move cursor to such object. The measurement results will appear near the cursor.

Left click on the selected object to enter the measurement results to the Information window.

Message window with the measurement results will be displayed. The selected object is highlighted.

Window management and its menu commands are described in Section 3.8.1.2.

You can view lengths of other objects by moving cursor to them. To enter measurement results to the Information window click sequentially on these objects.

The selected objects are highlighted. The Message window will display the list of measured lengths. The sum of the measured values will appear at the end of the list.

Select multisegment curve in Design Tree to measure its full length.

If you need to measure a face perimeter, select that face right after calling the command. In that case, the sum of measured values will represent its perimeter.

Reselect an object to exclude it from the list. Highlighting will be removed, the record on its length will be deleted from the window, and the sum of lengths— calculated again.

Objects can be selected before calling the command. After calling the command, Information window with measurement results appears on the screen.

Depending on the measurement results, you can create measurement objects (see Section 2.15.2.1.1 on p. 815).

2.15.2.3. Area

To measure the area of part faces, call command **Area**.

To measure a face area, move cursor to such face. The measurement results will appear near the cursor.

Left click on the selected face to enter the measurement results to the Information window.

Message window with the measurement results will be displayed. The selected face is highlighted.

Window management and its menu commands are described in Section 3.8.1.2.

You can view areas of the other faces by moving cursor to them. To enter measurement results to the Information window click sequentially on these faces.

The selected faces are highlighted. The Message window will display the list of measured areas. The sum of the measured values will appear at the end of the list.

To exclude a face from the list, indicate it again. Highlighting will be removed from this face, the record on its area will be deleted from the window, and the sum of areas— calculated again.

Objects can be selected before calling the command. After calling the command, Information window with measurement results appears on the screen.

Depending on the measurement results, you can create measurement objects (see Section 2.15.2.1.1 on p. 815).

2.15.2.4. Model Mass Properties

To calculate mass properties for the current model, call the **Model's MP** command.

By default, brief model information will be displayed in the Information window. These are the following data:

- ▼ Model surface area
- ▼ Model volume
- ▼ Model mass
- ▼ Center of mass coordinates according to the absolute model coordinates.

To see additional info, deactivate the **Brief** option on the Property bar. The following data will be displayed in the Message window:

- ▼ Axial moments of inertia (in absolute, central and world coordinate systems)
- ▼ Products of inertia (in absolute and central coordinate systems)
- ▼ direction of principal axes of inertia.

The **Mass Center** button on the Property Bar controls displaying model's mass center. If the button is enabled, the ghost of the main central system of coordinates. Axes of this system of coordinates are designated as J1, J2, and J3 (main inertia moments in the descending order of their values).

To create a point in the center of mass, activate the **Point** option on the Property bar, and then click the **Center of Gravity** button. A point called as "Point in CG" will be created in the model.

The **Point in CG** will not change its position when editing model in future. To create a new point corresponding to actual mass center, use the **Model Mass Properties** once again.

2.15.2.5. Deviation of Surfaces

You can measure distance between two objects. Such objects can be coordinate and auxiliary planes, faces, surface objects.

Further, the **surface** term will be used for measurement objects designation.

To measure the distance between the surfaces, call the **Deviation of Surfaces** command. Then specify surfaces one by one in the model window. Surfaces can be specified prior to calling the command.

Distances are measured between points of the first surface and their projections to the second surface in the specified direction.

The number of points is defined by the user, their location on the surface is defined automatically. Direction of measurement depends on the selected method of measurement:

- ▼ normally to the first surface,
- ▼ parallel to the selected guide object.

You can choose the measuring method using the switches from the **Method** group.

Switches of the **Direction** group are used to choose the direction of measurement: direct, reversed, or in both directions. In the Model window, the direction of measurement is shown by the ghost. It should match the direction to the second surface, otherwise the measurement will fail.

Both measurement directions depend on the surfaces' form and relative position. For example, let the measured surfaces sectioned by plane have the following view shown in Fig.2.15.2 Measurement is made using the guide object. If you make measures only in one direction, then a part of distances will not be measured; the figure illustrates the lines of these measurement by intermittent points. To measure all distances between the surfaces, select option **Two Directions**.

Fig. 2.15.2. Section of Surfaces

The user should make the decision about the necessity of performing measurements in both directions.

Fields with the **Points in U** and **Points in V** counter serve to set the number of points of measurement for **U** and **V** parameters. By default, field values are equal to 20. The total number of measurements is equal to the product of the fields' values.

Fields with the **Minimums** and **Maximums** counter serve to set the number of the first sought minimums and maximums the parameters of which are displayed in the Info window. By default the value of these fields is 1.

The **Briefly** option serves to choose the number of measures, parameters of which will be shown in the Information window as a result of the command execution. If this option is enabled, only the first sought maximums and minimums will be displayed. If the option is disabled, all the results of measurements will be displayed.

The measurement results are shown in the Information window.

Window management and its menu commands are described in Section 3.8.1.2.

It contains the following parameters:

- ▼ Number of measurements,

Number of measurements does not necessarily coincide with the specified number of points. E.g. the measurement is not performed if the measuring line does not intersect the second surface.

- ▼ Minimum distance between surfaces in the points of measurement,

- ▼ Maximum distance between surfaces in the points of measurement,
- ▼ Simple average of distances in the points of measurement,
- ▼ Absolute minimum of distance between surfaces,

The measuring point of the absolute minimum does not necessarily coincide with the points of the defined set.

- ▼ Specified number of measurement results that are the closest to minimum distance (the first sought minimum values),
- ▼ Specified number of measurement results that are the closest to maximum distance (the first sought maximum values).

For each measurement from the first sought minima and maxima the following data set is displayed (see Fig.2.15.3):

- ▼ measured distance,
- ▼ point of measurement coordinates on the first and the second surfaces,
- ▼ arithmetical average distance.

If you measure the distance in both directions, a measurement direction arrow appears in the beginning of each row with measurement results. Direct measurement is marked with the error pointed to the left, reverse measurement— error pointed to the right.

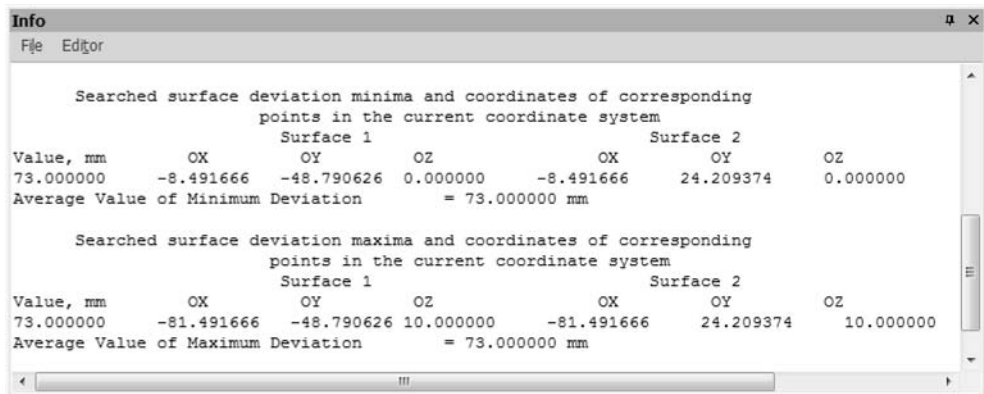

Fig. 2.15.3. The first minimum and maximum measurement results in the Information window

If while running the command, the display of full set of measurement results is selected, the coordinates of measurement points and the measured distance will be displayed for all measurements.

If during the current command session a remeasurement is made, the results of the previous measurement shown in the Information window will be replaced by the new ones without saving. In order not to lose the measurement results it's necessary to save them into the file on disk using the commands of the Information window's menu.

2.15.2.5.1. Measuring Normal to Surface 1

In order to make the measurement it's necessary to click the **Normal to Surface 1** switch.

In the model document window, select the surface to measure the distance from. The object name will be displayed in the **Surface 1** field.

Select the second surface. The object name will be displayed in the **Surface 2** field.

Coordinate or auxiliary plane may be selected as the second surface.

Select the direction of measurement so that the arrow ghost is directed from the first surface to the second. If the measuring direction is chosen incorrectly, an attempt of the command executing will result in the display of the message *Calculation parameters are set incorrectly*.

Define the number of measurements for the **U** and **V** parameters as well as the number of the displayed minima and maxima of the measured values.

Using the **Briefly** option define the range of measurements results displayed in the Information window.

To perform measurements, click the **Create Object** button on the Properties bar.

The measurement results will be shown in the Information window. In the model window the measuring lines connecting the measuring points of the first sought minima and maxima will be shown. Measurement lines of the first sought minimums values are shown with solid lines, and the first sought maximums values — with dotted lines.

The system will wait for changing of the command parameters for further measurements.

The **Interrupt Command** button is used to stop execution of the command.

2.15.2.5.2. Measurement using the guide object

To perform a measurement operation click the **Guide Object** switch.

In the model document window, select the surface to measure the distance from. The object name will be displayed in the **Surface 1** field.

Select the second surface. The object name will be displayed in the **Surface 2** field.

Coordinate or auxiliary plane may be selected as the second surface.

Select a guide object. The following objects can be selected as guide objects:

- ▼ Straight objects: axis, line segment, straight edge, polyline segment. When selecting a straight object, measurements will be done parallel to it.
- ▼ Flat: flat face, coordinate or auxiliary plane. When selecting a flat object, measurements will be done perpendicular to it.

If there is no required guiding object in the Model, you may construct a direction vector (see Section 2.8.5 on p. 613).

Select the direction of measurement so that the arrow ghost is directed from the first surface to the second. If the measuring direction is chosen incorrectly, an attempt of the command executing will result in the display of the message *Calculation parameters are set incorrectly*.

Define the number of measurements for the **U** and **V** parameters as well as the number of the displayed minima and maxima of the measured values.

Using the **Briefly** option define the range of measurements results displayed in the Information window.

To perform measurements, click the **Create Object** button on the Properties bar.

The measurement results will be shown in the Information window. In the model window the measuring lines connecting the measuring points of the first sought minima and maxima will be shown. Measurement lines of the first sought minimums values are shown with solid lines, and the first sought maximums values — with dotted lines.

The system will wait for changing of the command parameters for further measurements.

The **Interrupt Command** button is used to stop execution of the command.

2.15.3. Intersection Detection

Sometimes, one of the purposes of assembly model is to find out the locations of unwanted intersections and tangencies between components (“stumbings” in a design).

To detect such places, click the **Intersection Detection** button on the **Measurements and diagnostics (3D)** toolbar or select its name from the **Service** menu.

After the command is called specify one by one the components or the bodies, that have to be checked for intersection. The selected objects will be shown in the **List of Objects** on the Properties bar.

- ▼ If components are selected for checking, then the intersections will be found between the bodies which belong to these components (not between the bodies that belong to one component). Components are selected in the Design Tree.
- ▼ If bodies are selected for checking, then the intersections will be found between them. Bodies can be selected both in the Model Tree and the Model window.

If you also need to identify tangencies of components of bodies, enable the option **Consider Tangencies as Intersections**.

After selection of components click the **Detect Intersections** button on the Advanced Control Panel.

In the **Intersections Detected list** on the Property Bar, the serial number of intersection and the names of intersecting (tangential) objects will appear. The model window will display an area frame of their intersection and/or tangency line.

To escape the intersection detection command, press <Esc> key or click the **Interrupt Command** button.

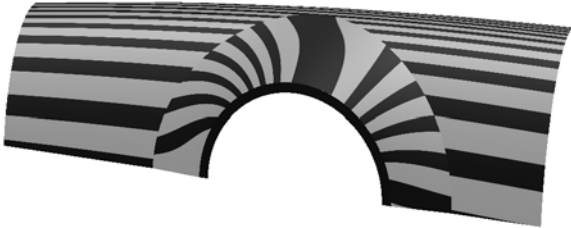

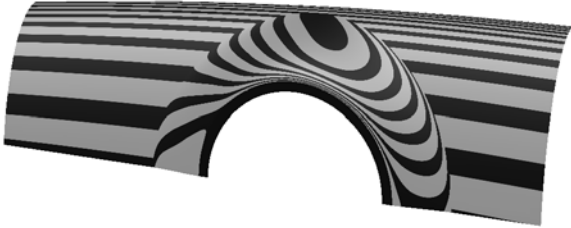

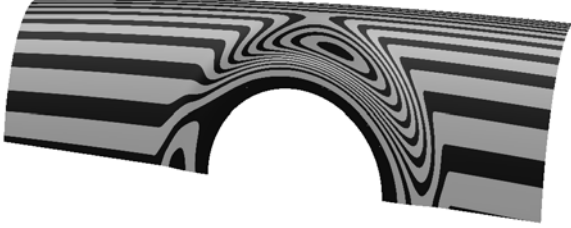

2.15.4. Check the model surfaces for smoothness

When modeling parts (for example, box-type parts), it may be necessary to check surfaces for smoothness thoroughly. For the visual assessment of model surface smoothness, a special mode to display body is used.

In this mode, all faces of the model are represented as mirroring the environment, for example, color bars on the spherical surface. You can visually evaluate the smoothness of surface edges' joints (see Table 2.15.3), and identify subtle curvature changes inside the edges (see Fig. 2.15.4).

Enabling the special model display mode is described in Section 2.15.4.1; information about display settings can be found in Section 2.15.4.2.

Tab. 2.15.3. Assessment of smoothness of the faces' intersections using "Zebra"

Face mating condition	The form and arrangement of the "zebra's" stripes meeting the mating condition
Not specified	Stripes do not adjoin on edges: 
By Tangent	Stripes on edges adjoin with a bend: 
Smooth	Stripes on edges adjoin smoothly: 

2.15.4.1. Enabling model smoothness check mode

In order to enable the model smoothness check mode, call the **Smoothness check mode** on the **Modes** bar or select its name in the **Service — Smoothness check** menu. After calling it, model appearance changes. By default, the **Zebra** method of display is used.

Fig. 2.15.4. Check surface for smoothness
(the surface is a little convex):

- a) dimmed wireframe display of the model— the convex is practically invisible;
b) model's smoothness check mode (**Zebra** method) – the convex can be clearly seen

When working with the document, you can set the model display parameters (for example, change the width of “zebra's” stripes or choose another method of display— **Reflection of the environment**). In this case, model appearance corresponds the settings made.

Model display methods and setup of corresponding them parameters are described in Section 2.15.4.2.

The smoothness check mode usage causes an extra load on the memory and operating system resources resulting in a slow-down of the KOMPAS-3D system.

2.15.4.2. Display parameters setup

Smoothness check mode parameters can be customized. The setting is accessible if there is at least one surface in the Model.

To perform setup, call the **Smoothness check parameters** command by one of the following methods:

- ▼ by choosing from the menu of the **Smoothness check mode** button on the **Modes** bar.
- ▼ by choosing from the **Service — Smoothness check**.

Model appearance will change (if model smoothness check mode is not enabled in the document). The display parameters management interface items will appear on the Property bar.

Two model display methods are possible:

- ▼ **Zebra** is a sphere with stripes is reflected on the model's edges (this method is used by default),
- ▼ **Environment reflection** is a sphere with the bitmap image from file applied to it is reflected on the model's edges.

In this case, model is located inside an imaginary sphere.

Model display method is selected from the same-name drop-down list.

For **Zebra** method, set the color and display parameters of stripes (see Section 2.15.4.2.1).

For **Environment reflection** method, select the file with the required image and set its display parameters (see Section 2.15.4.2.2 on p. 825).

When changing model display parameters, its appearance automatically changes in the window.

If the boundaries of the displayed stripes or sections of the selected image have irregularities, enable the **Enhanced drawing precision** option. The boundaries will be more regular.

To finish the command, click the **Interrupt Command** button on the Special Control Panel. If the smoothness check mode is not enabled in the document, the model will take its previous shape. If this mode is enabled, the model display will correspond the settings made.

Model display parameter settings remain effective till the end of the current document working session.

2.15.4.2.1. Zebra display method

By default, black stripes on white background are used for this method of displaying the model. You can customize band parameters and change their color using the control elements of the Properties bar (Fig.2.15.5). Background color cannot be changed.

Fig. 2.15.5. Color and stripes parameters control elements

Stripe Color field serves to change color of the stripes. To select the required color, you need to click on the triangle in the right part of the field and specify color in the color palette appeared on the screen.

To set the parameters of the stripes, use the **Zebra parameters** bar. The bar contains preview area and fields corresponding to the following parameters:

- ▼ frequency of the stripes,
- ▼ width of the stripes,
- ▼ boundary feathering,
- ▼ rotation,
- ▼ transparency.

The slider in each field serves to control corresponding parameter value. The preview pane is used for visual assessment of the changes made— it reflects the sphere with stripes on it. When changing color or parameter values, the image in the preview area automatically changes.

2.15.4.2.2. Environment Reflection method

To get a model image by this method, an image, which is contained in a BMP, GIF, JPEG, PNG, TIFF or TGA format bitmap file, is used. Using property bar control elements (Pic. 2.15.6) you can choose the required file and set parameters of the image superimposing on the reflected sphere.

Fig. 2.15.6. Image selection elements and setting parameters of its superimposing on the sphere's surface

To select the file, you need to click **Image File** button and specify the required file in the standard file selection dialog. The full name of the file shall appear in the **Source File** field. The **Reflection parameters** bar will become available to set the parameters of the selected image superimposition on the surface of the reflected sphere.

The bar contains preview area and fields corresponding to the following parameters:

- ▼ horizontal shift,
- ▼ horizontal scale,
- ▼ vertical shift,
- ▼ vertical scale,
- ▼ rotation,
- ▼ transparency.

The slider in each field serves to control corresponding parameter value. The preview pane is used for visual assessment of the changes made— it reflects the sphere with the image on it. When selecting other image file or parameter values, the image in the preview area automatically changes.

Path to the folder with images (i.e. the folder available by clicking **Image File**) can be set in the PICTURES environment variable KOMPAS-3D (see Section 9.5.4 on p. 1886). By default, this folder is *Samples\Surfaces\Maps* relative to the main system installation folder. If you want to change the default path to the folder with images, then use the *Kompas.ini* file (see Section 9.5.3 on p. 1883).

2.15.5. Model Section

During modeling a model, you may find it difficult to assess whether the parts and nodes of the assembly model are placed correctly and whether the construction items of a part and thickness of its walls are appropriate. In this case, use the model section mode for visual control purposes.

When this mode is on, the model is displayed as a trimmed place or a set of planes. The position of the cutting plane (or planes) can be set when creating the model section (see Section 2.15.5.2 on p. 828).

You can create multiple section in a model. One of them is active.

To enable the model section mode, choose **View— Model Section — Display Section** or click **Model Section** on the **View** panel.

If no sections are available in the model, then choosing the command will launch the section creation process. If there are any sections in the model, the model's appearance will be updated. The model will be displayed trimmed by the current section and the model section mode icon will appear in the top right corner of the model window.

You can make another section a current one. To do this, select in from the drop-down menu of the **Model Section** button. The model appearance in the window will be automatically updated.

The section mode is also enabled once the section is created. The created section becomes the current one.

You can perform any operations of object construction, modification, enable other modes (for example, the context editing mode, the sketch mode, etc.) in the model section mode.

When operations are performed, model vertices, edges and faces, including trimmed ones, can be clicked unlike section vertices, edges and faces.

To finish work in this mode, go to **View — Model section — Display section** again, click **Model section** in the **View** bar again or click the mode icon in the model window.

To create a set of sections in the model, use the **Model Sections** dialog described in 2.15.5.1. In this dialog, you can create, remove or change the sections as required.

2.15.5.1. Section Management

To create a set of section, use the **Model Sections** dialog (Fig. 2.15.7). To access the dialog, choose **Section Management...** command from the **View — Model Section** menu or from the drop-down menu of the **Model Section** button on the **View** panel.

Fig. 2.15.7. The **Model Section** dialog

The dialog provides a list of sections created in the model as well as controls for managing the sections.

The list of properties has the table form. It allows you to rename sections or change their statuses.

To rename a section, double-click the corresponding cell in the table and type the name you want.

If you want to make the section a current one, choose the row of this section in the table and click **Current Section** on the dialog toolbar or double-click the *Status* cell corresponding to this section. When the section mode is on, the model appearance in the window will be automatically updated.

If the section mode is off, you can enable it without closing the dialog. To do this, click **Model Section Mode**. Clicking the button again will disable this mode. When enabling/disabling the mode, the dialog is displayed on the screen.

To create a new section, click the **Create section** button and perform the steps described in Section 2.15.5.2.

Using the **Edit Section** button, you can change the section parameters (see Section 2.15.5.3 on p. 833).

Once you click the section creation or editing buttons, the **Model Section** dialog will be closed.

To delete an object, select it in the list and click the **Delete** button. If this section is current, the following section in the list becomes current after its deleting.

After performing all necessary operations in the dialog, close it.

Actions performed in the dialog cannot be undone.

2.15.5.2. Creating a Section

A model section can contain multiple cutting steps. You can configure individual parameters for each step. By default, a section contains only one step. You can add the required number of steps when creating or editing a section.

On each step, a certain fragment of the model is trimmed by one or more planes. The number of planes depends on the mode you've previously chosen for setting the step parameters.

You can create as many cutting steps as required, however each model section cannot contain more than 6 section planes.

You can launch the section creation process in the following ways:

- ▼ by calling the **View — Model Section — Display Section** command or clicking the **Model Section** button on the **View** panel when no sections have been created in the model yet,

- ▼ by clicking the **Create Section** button in the **Model Sections** dialog.

The model window will then display a ghost of the section plane, and the Properties panel will display the **Parameters** (Fig. 2.15.8) and **Properties** tabs.

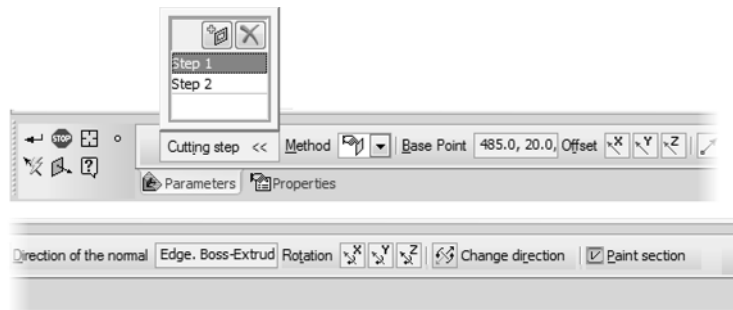

Fig. 2.15.8. Creating a model section, the **Parameters** tab

The section plane ghost is placed alongside the XY plane of the absolute coordinate system. This location of the plane corresponds to the first cutting step. You can also set another parameters of the first step as well as add additional steps as required.

The list of cutting steps is available on the **Cutting Step** panel of the **Parameters** tab. By default, it contains only one step.

When the parameters you've provided are insufficient for creating a cutting step, the system will display the (!) signs to the right of the step name in the list.

Specify the required parameters for the first cutting step. A set of parameters depends on how you choose to place the section plane in the **Method** drop-down list. The following methods are available:

- ▼ **Free Placement** (see Section 2.15.5.2.1),

- ▼ **Offset Plane** (see Section 2.15.5.2.2 on p. 831),

- ▼ **Rotated Plane** (see Section 2.15.5.2.3 on p. 832),

- ▼ **Outline Box** (see Section 2.15.5.2.4 on p. 833),

- ▼ **Zone** (see Section 2.15.5.2.5 on p. 833).

In some cases, objects available in the model are used when setting cutting step parameters. For example, when you place a section plane using the **Rotated Plane** method, the base plane and the revolution axis are placed relative to the objects you've selected. To change the object, click the **Reselect** button on the Advanced Control panel.

When **Free placement**, **Offset plane** or **Rotated plane** is used for positioning the section plane, you can manage the cutting direction. In case of free placement of a plane, the cutting direction is shown by Z axis of the positioning element, in case of plane offset or rotation — the blue arrow. To change the face extension direction click the **Change Direction** switch.

When using these placement methods, you can also enable the model orientation, so that the section plane is parallel to the screen. To do this, click **View Along the Normal of the Section Plane** button on the Advanced Controls Panel.

For the **Offset Plane** and **Rotated Plane** methods, the **Change Direction** and **View Along the Normal of the Section Plane** will become available once you choose the base objects.

If you want to add multiple cutting steps in the section, create a new step by clicking the **Add Cutting Step** button on the **Cutting Step** panel. A new step will appear in the list. Choose a building method and specify the placement parameters for the section plane as described above.

To remove a cutting step, select it in the list and click **Delete**.

To display one or more ghost edges on the place where the created plane intersects the model, enable the **Fill Section** option. A color and optical properties of this edge can be set on the **Properties** tab (see below). The ghost face is not an object and is displayed only when the section mode is enabled.

To hide the ghost edges in the mode, disable this option. This can help you to visually assess whether the components of the assembly model are placed correctly (e.g. whether any components intersect each other).

The **Paint section** option is enabled/disabled for the entire newly-created section rather than its individual steps, i.e. ghost faces are displayed (or not displayed) for all cutting steps.

You cannot use any ghost edges as well as its edges and vertices for performing any operations in the model. They are not able to be selected.

To assign a name to the new section, expand the **Properties** tab and type the name you want in the **Name** field.

You can also set the color and optical properties of the ghost edge on this tab. To do this, use the **Set Color** group of controls. The following options of a flat object setting are available:

▼ **By the source object**,

▼ **Manually**.

When setting a color manually, you can also configure the optical properties. For details on how to set the color and optical properties, see Section 2.14.2 on p. 784.

In order to finish creating the report, click the **Create Object** button. The newly created section becomes the current one. The model appearance is updated. The model is now trimmed with the planes of this section, i.e. the model section mode is enabled.

2.15.5.2.1. Free Placement of a Section Plane

To activate the free placement of a section plane, you can use the controls on the Properties panel (see Fig. 2.15.8 on p. 828) or the special positioning control.

Placement of a plane includes setting the position of the reference point which defines the position of the plane in the model and setting the orientation of the plane.

The model window will display the special positioning control which overlaps with the reference point. It is a kind of a coordinate system consisting of three large arrows of red, green and blue colors which correspond to the positive directions of the X, Y, and Z axes. The planes perpendicular to the arrows display the arcs of the corresponding colors. The center point of the control is marked with a sphere or a cube (the cube is displayed when the reference point is associated with a model object). The XY plane of the control overlaps with the section plane you are creating. The positive direction of the Z axis shows the cutting direction.

You can change the position of the reference points for the section plane by moving this control. Rotating the control will change the orientation of the plane in the model. For details on how to move and rotate the control, see Section 2.11.2.5.3 on p. 696.

If a reference point of the section plane is associated with an object (the center point of the control is marked with the cube), you cannot move the control arbitrarily. However, you can delete the association by moving the control along the axis.

You can also use one of the following methods to set the position of the reference point.

- ▼ Selecting a point object in the Design Tree or the Model Window. In this case, the reference point will be associated with this object.
- ▼ Set the offsets along the coordinate axes. To move the plane along the required axis, activate the switch for this axis in the **Offset** group:
 - ▼ **Offset by X axis,**
 - ▼ **Offset by Y axis,**
 - ▼ **Offset by Z axis.**

The **Offset** field will appear on the Properties bar. In this field, enter the distance that the plane should be set off for.

- ▼ Point creation. This will create an association. Click the **Create Object** button on the Special Control Panel. This will initiate the process of point creation (see Section 2.5.2.11.1 on p. 347). Select a construction method and specify the required parameters. These parameters will define the position of the reference point. Note that in this case the point building process is used only for defining the position of the reference point. No new point is created in the process. After the point is created, the system will proceed with creating the plane.

The Properties panel provides the **Reference Point** field. This field is for information only (you cannot change its value). Depending on the positioning method used for the reference point, the field can display either coordinates of the reference point or the name of the object it is as-

sociated with. The content of this field changes automatically when the position of the reference point changes.

You can use the following methods for setting the orientation of the plane.

- ▼ Specify an object which defines the normal to the section plane (the normal overlaps with the Z axis of the positioning control). The object is specified on the Design Tree or in the model window. Objects of the following types are available:
 - ▼ straight objects — the normal is parallel to the object,
 - ▼ flat object (including a sketch and a flat curve) — the normal is perpendicular to the object plane,
 - ▼ revolution surface — the normal is parallel to the revolution axis.

You can choose a sphere only when it owns the reference point of the plane. In this case, the normal overlaps the perpendicular line to the sphere in the reference point.

- ▼ Setting the section plane rotation angle about the axis of the positioning element.

In group **Units make** active one of switches:

- ▼ **About X axis,**

- ▼ **About Y axis,**

- ▼ **About Z axis.**

The **Angle** field will appear on the Properties bar. Enter the required value of the angle in this field. The section plane ghost will rotate about the selected axis to the entered angle.

- ▼ Vector Drawing

Click the **Create Object** button on the Advanced Control Panel. The vector creation process will be launched (see Section 2.8.5 on p. 613). Select a construction method and specify the required parameters. The model will display a ghost of a vector with the specified direction. Finish building the vector. The system will resume the object construction process. The section plane's normal will be parallel to the vector and will have the same direction.

The Properties panel provides the **Direction of normal** field. This field is for information only (you cannot change its value). Depending on the direction setting method for the section plane's normal, the field will display either the guiding object name or the coordinates of the normal vector. When the normal is defined by a vector, the word *Vector* is also shown in this field.

When you change the orientation of the plane, this field is automatically updated.

2.15.5.2.2. Offset Section Plane

Once you select the **Offset Plane** positioning method, the Properties panel will display the controls shown in Fig. 2.15.9.

Fig. 2.15.9. **Offset plane** Method

To set up inscription location parameters, do the following.

1. In the Design Tree or in the Model Window, specify a flat object (a plane or a flat edge) which will then be used as a base plane.

The **Base Plane** will display the name of the selected object and the model window will show the section plane ghost overlapping the base plane. The flat object you've selected is highlighted. The cutting direction is shown with a blue arrow.

2. Specify the offset of the section plane relative to the base plane.

To do this, enter the value you want in the **Distance** field. The plane will then be shifted to the distance you've specified.

You can also shift the plane manually. To do this, move the blue arrow which denotes the cutting direction. The following methods are available:

- ▼ arbitrary distance — drag the cursor,
- ▼ exact distance — click the arrow and type the offset value in the field that appears.

When shifting the plane manually, the **Distance** field is automatically updated.

2.15.5.2.3. Reversed Section Plane

Once you select the **Rotated Plane** positioning method, the Properties panel will display the controls shown in Fig. 2.15.10.

Fig. 2.15.10. The **Rotated Plane**< method

To set up inscription location parameters, do the following.

1. Select a flat object (plane or flat face) which will be used as a base plane in the Design Tree or in the Model window. The object you've selected is highlighted in the model window and its name is displayed in the **Base Plane** field.
2. Specify an axis around which you want to rotate the section plane. To do this, choose a linear object (an edge or an axis) on the base plane or on any plane parallel to the base one either in the Design Tree or in the model window.

The **Axis** field will display the name of the object you've specified and the model window will display the ghost of the section plane. It goes through the selected axis parallel to the base plane (or overlaps with it). The cutting direction is denoted by the blue arrow while the rotation plane is denoted by the arc.

3. Specify the rotation angle around the axis you've chosen.

To do this, enter the inclination angle value in the **Angle** field.

You can also rotate the plane manually. To do this, use the arc which denotes the rotation plane. The following methods are available:

- ▼ arbitrary angle — drag the arc with the cursor,
- ▼ exact distance — click the arc and type the rotation angle value in the field that appears.

When rotating the plane manually, the **Angle** field is automatically updated.

2.15.5.2.4. Box-like Section

A model section can be box-like. The part of the model that is outside the parallelepiped is cut. To create such a section, use the **Box** method. When you select this method, the Properties panel will display the controls shown in Fig. 2.15.11.

Fig. 2.15.11. The **Box** method

In order to set parameters of the parallelepiped, do the following.

1. Choose the box definition type. To do this, enable one of the following switches in the **Option** group:

▼ **By two vertices,**

▼ **By center and vertex,**

2. Position parallelepiped points.

The position of the first point is set when the **Point 1** switch is active and that of the second one — when the **Point 2** switch is active.

Point coordinates can be input from a keyboard or defined automatically by positioning the point with the mouse in the model window or selecting a point object. These operations are similar to those described in Section 2.5.2.2 on p. 336.

You can also specify the coordinates using the point construction process which can be launched by clicking the **Point Creation** button on the Advanced Control Panel (see Section 2.5.2.11.1 on p. 347). The parameters set during this process define the position of the box point. No new point is created in the process.

Once you set the coordinates of any point of the box, its ghost will appear in the model window.

2.15.5.2.5. Section by Zone

If the model contains zones (see Section 2.15.14 on p. 853), you can select any of them when setting the parameters of a cutting step. To do this, use the **Zone** method. If you choose a zone, all model segments outside this zone will be cut off.

The right zone is selected in the **Zones** tab of the Model Tree. The zone ghost appears in the model window and the zone name — in the **Zone** field of the Properties bar. A second click on the zone cancels its selection.

2.15.5.3. Editing Section Parameters

When you need to edit the parameters of the model section, choose this section in the **Model Section** dialog and then click the **Edit Section** button (see Section 2.15.5.1 on p. 826).

The model window will display a ghost of the section plane, and the **Parameters** and **Properties** tabs will become available on the Properties bar. These tabs provide the same set of controls as when you create a section.

You can edit the parameters of the cutting step you want. To do this, select it on the **Cutting Step** panel and perform the actions described in Section 2.15.5.2 on p. 828. You can also add or remove the cutting steps.

2.15.6. Receiving Info on Model and its Objects

While working with model, you can get reference data about the current part or assembly, or else any object of the part: edge, face, element, surface, component etc. Click the **Object Info** button on the **Measurements (3D)** bar or select the command from the **Service** menu.

To quickly obtain information on any object, move the cursor to it in the model window. The object's symbol and basic data will appear near the cursor (Figure 2.15.12).

Fig. 2.15.12. Quick Viewing of Edge Info

Left-click the selected object.

The Information window will pop up.

Window management and its menu commands are described in Section 3.8.1.2.

By default, the Message window provides brief information on an object, i.e. only basic data (see Section 2.15.6.1). If necessary, you can also get additional data on the object (see Section 2.15.6.2). For this, disable the **Brief** option on the Property Bar and select the object once more.

The object or objects which information you need to obtain can be also selected before the command is called.

Certain objects can be selected only in Tree, for example, assemblies, parts, elements, sketches, polylines, other— only in the window, for example, edges, faces, vertexes, sketch contour, polylines segments and others— both in Tree and in the window, i.e., central point, auxiliary and construction planes, points, splines.

If objects were selected in the Tree or in the model window before the **Object Information** command was called, the Information window pops up right after the command is called and contains data on those objects.

The Information window provides brief information on an object – basic data (see Section 2.15.6.1).

Sketch should be specified in the Design Tree.

To view information about another object, move the cursor to it. When you click the object, its data will be added to the Information window.

On Property Bar, you can also set the accuracy of calculations, units of length and angle measurement. Change of these parameters is displayed immediately in the Info window.

To finish the command to retrieve info, click **Interrupt Command** button on Advanced Control Panel or close the Info window.

2.15.6.1. Basic Information

Basic information about object:

- ▼ Number of measurement
- ▼ Name of object
- ▼ Object type. Data on type of object are obtained from mathematical description of object. Example:
 - ▼ Edge can be of type *line*, *arc of a circle*, *spline* and others;
 - ▼ Face or surface can be of type *plane*, *toroidal*, *ruled surface*, *spline surface* and other.
 Certain objects, e.g., point or element, do not have a type.
- ▼ Numerical parameters of an object. Set of parameters depends on the object:
 - ▼ For objects, being a kind of a curve line (edge, 3D line, sketch line, etc.), length value is set
 - ▼ For cylindrical, spherical and circular objects (rounding surface, edges and contours as circles/arcs of circle, etc.) radius and diameter values are to be set
 - ▼ For points coordinates are defined
 - ▼ For planes, you should define coordinates of normal vector, etc.

Object parameterization also includes names and values of this object's variables.

For parts and assemblies, values of some system properties (file name, date of creation, and so on; more information about system properties can be found in Section 5.1.3.1 on p. 1380) are specified; for assemblies, general data about the number of first-level components, mates, and elements is specified.

Components of First Level are parts and sub-assemblies being integral part of the current assembly. Components, included into subassemblies (and also subassemblies of subassemblies, etc.), are not components of first level for the current assembly.

- ▼ If the Tree displays the sequence of model construction, the first level components are located on the first level of Tree.
- ▼ If the Tree displays the structure of model, the first level components are located on the first level of section "Components".

2.15.6.2. Additional Information

Additional information on object:

- ▼ Color and visual properties of object
- ▼ Relations in form of lists of initial and derivative objects
- ▼ For faces: parameters of bounding edges, for edges: parameters of final vertices
- ▼ For a variant (i.e. Variant Tree object): numbers of initial and derivative variants.
- ▼ For assemblies: number of components of all levels, i.e., total of components of the first level and other components.

2.15.7. Exploding of Assembly Components

Sometimes, it is necessary to view an assembly in an “exploded” state (so that to see all its components).

Before exploding components, you need to set up the exploding parameters: select components and set the direction and value of their relocation.

To set explosion parameters, call command **Service— Explode Components — Options**.

The same component can be involved in several exploding steps.

One exploding step may involve several components.

A component belonging to a sub-assembly (at any nesting level), can be involved in an explosion step irrespective of other components in the sub-assembly.

Fig. 2.15.13. Exploding Properties

On Property Bar (Fig.2.15.13) a list of components of explosion steps will pop up.

If the exploding parameters setup of the current assembly was not done yet, the list will be empty.

To add explosion step, click **Add** button.

Then select components, included in explosion step, and parameters of this step:

1. To select components, enable option button **Components** and select the objects required.

2. To define components explosion direction, enable option button **Object**. Components can be exploded in the direction, coinciding with the model's edge (for this, select the required edge in the assembly window) or in the direction, perpendicular to the face (for this, select the required face).

3. Enter the **Distance** in the appropriate field where a component should be moved with respect to its original position.

4. Select direction of displacement of components— **Forward** or **Reverse** by enabling the corresponding option button in group **Direction**.

After setting the components explosion step parameters, click the button **Apply**. The selected components will be exploded according to the specified parameters.

If the resulting exploded state of components is other than expected, edit the exploding parameters.

Similar to that set the required number of explosion steps and tune their parameters.

To delete a step or a component from the list, click button **Delete** in the upper part of the list. Upon completion explosion step setting button **Interrupt Command** on Advanced Control Panel.

After exit from the step setting command, the assembly in the window is displayed in the exploded view mode.

To enable the normal mode of the assembly display, call the command **Service— Explode Components — Explode**. Button for command calling is on panel **Modes**. This command serves to switch between the exploded mode and the normal assembly display. When components are exploded, the button is enabled, and the words “Exploded View” in round brackets are added to the document name in the window title. The document window will display the mode icon notifying that the assembly is currently displayed in the exploded view. To exit the exploding mode, simply click this icon.

When an assembly components are exploded, no assembly editing commands are available (including the **Edit in Window** command), nor the commands for creating 3D curves, surfaces, auxiliary objects, appearance elements, mating commands and commands to work with a BOM.

A subassembly cannot be displayed in assembly window in the exploded state.

2.15.8. 3D Macro Element

A **3D macro element** is a group of model objects. By grouping objects logically into macro elements, you can lay out the Design Tree in a more compact way. This simplifies navigating through the Tree, especially, when working with complex models containing numerous objects.

It is helpful to group objects into macro elements, sharing common function or design purpose.

Objects included in a macro element are displayed in the Design Tree as dependent objects of that macro element and are marked with icons-folders. The procedure of working with them is the same as with objects not included into macro elements: they can be edited, excluded from calculations, deleted etc. Besides, the objects included in a macro element can be used in operations (i.e., copying).

3D macro elements can be nested into each other. The number of nesting levels is unlimited. In other words, you can include into a macro element:

- ▼ several existing macro elements,
- ▼ objects, belonging to any of the existing macro elements.

On Fig. 2.15.14 a macro element *Lug* is shown as an example. It contains the following objects: a lug with outer and inner bosses and a hole, also holes for screws. The bosses and the screw holes are, in their turn, grouped in the same-named macro elements, dependent on the *Lug* macro element.

Fig. 2.15.14. Lug Macro element: a) display in the Design Tree, b) model objects, included in the macro element (marked)

By selecting a macro element icon in the Design Tree, all objects included into that macro element are highlighted.

2.15.8.1. Creation of 3D Macro Element

To create a new macro element in the model, call **Service— Create Macro Element** command.

Below the Design Tree macro element shall appear, not containing any object. You can add model objects to it (see Section 2.15.8.3 on p. 840).

To group several existing object in a macro element, select them in the Design Tree and call the **Group into Macro Element** command from the context menu or from the **Service** menu.

A macro element containing indicated object will appear in the position of the bottommost object in included in that macro element. The icons of the objects will be placed at the level following the macro element level. The objects placement order in a macro element is the same as their placement in the Tree before the macro element creating.

If the model design sequence is displayed in the Tree (see section 2.1.2.1 on p. 106), all macro elements are in the *Macro* section.

Pay attention to the fact that macro element can group only such objects that belong to the same “parent” object and are located on the same level, except:

- ▼ Bends in a sheet element (i.e., bends making up a cutting down of)
- ▼ Array instances.

Thus, it is impossible to combine into the macro element the objects, belonging to:

- ▼ Different components of an assembly
- ▼ The macro element and the whole model

- ▼ An assembly component and the whole assembly, etc.

2.15.8.2. Handling the Contents of Macro Element Display

There are two modes of displaying a macro element in the Design Tree:

- ▼ With the contents display
- ▼ Without contents display.

If the contents display is enabled, then the “+” symbol is displayed in the Tree by the macro element icon. Clicking the mouse on this sign (turning it to “-”) opens the list of objects included into the macro element.

Fig. 2.15.15.

If the contents display is disabled, then the “+” symbol by the macro element icon is missing. You cannot view the contents of such macro element in the Design Tree.

Fig. 2.15.16.

The way of the macro element display in the Tree does not affect the display of its member objects in the Model window.

By default the display of a newly created macro element contents is enabled.

To disable the display of a macro element contents, select it in the Design Tree and call from the context menu **Hide Contents** command. To restore the contents display, call the **Show Contents** command from the macro element context menu. If several macro elements with different display settings are selected, then both commands are available in the context menu.

2.15.8.3. Altering the Macro Element Contents

As soon as the macro element has been created, you can change its contents by “dragging” objects in the Design Tree with the mouse.

- ▼ To add an object to a macro element, “drag” the object icon on the macro element icon.

When the cursor shape changes, “release” the object. It will be added to the contents of the selected macro element. If the object was located above the macro element in the Design Tree, the macro element position will not be changed after adding of that object. Otherwise, the macro element is moved to the position of the added object in the Design Tree.

- ▼ To exclude the object from a macro element, expand its contents (to do this, it is necessary to enable the macro element contents display, see Section 2.15.8.2 on p. 840). “Drag” the object icon in the Tree outside the Macro element.

When the cursor shape changes, “release” the object. It shall be excluded from the macro element to pop up in that place of Design Tree, where it had been before inclusion into the macro element.

-
- ▼ To move an object from the macro element into a specific position in the Design Tree, “drag” the object to that position. When the cursor takes on the shape of an arrow, “release” the object. If the cursor doesn’t turn into the arrow, that means the object being moved cannot be put in the specified position in the model object hierarchy.

The central point of the coordinates cannot be included into the macro element nor excluded from it with the mouse. To do this, it is necessary to use the **Group into Macro Element** and **Explode Macro Element**, commands accordingly.

You can also move objects between the macro elements with the mouse.

2.15.8.4. Destruction of the Macro Element

The macro element destruction is the reverse to its creation operation.

After the macro element is destroyed, its icon is deleted from the Design Tree, and its member elements are returned to their places.

The macro elements included into the destroyed one are preserved.

To destroy the macro element (macro elements), select it and call the **Destroy Macro Element** command from the contextual menu or from the **Service** menu.

2.15.8.5. Deleting Macro Element

The macro element deletion means both the element itself and its member objects deletion.

To delete a macro element (macro elements), select it and call the **Delete** command from the context menu or from the **Edit** menu.

After that, the object deleting dialog will be displayed. It lists all the objects included into the macro element. You can confirm or reject the deletion.

2.15.9. Deletion of the model construction history

If necessary, you can delete information about the methods of creating objects and links between them from the model's file. As a result, the model's appearance and its mass-centering characteristics will not change, but it will become impossible to trace back how the model was created and edit parameters of its objects.

Construction history can be deleted if it is no longer needed; for example, if model designing is finished. After deletion of construction history, rebuilding of the model will take less time, and the size of the model's file will be reduced.

The **Delete construction history** can be found in the **Editor** menu. Once the command is called, information about construction of the model will be deleted; the Design Tree will be modified, in particular:

- ▼ bodies/surfaces/curves are transformed into operations/surfaces/curves without history;
- ▼ the array transforms into a set of objects located in accordance with the arrays parameters;
- ▼ sketches, auxiliary axes and planes, layout elements, component matings are deleted;
- ▼ assembly components are fixed;
- ▼ if a component was edited by an operation in assembly, all of its objects are transferred to the assembly, while the component is removed from it;
- ▼ local coordinate systems, control and connection points are replaced by ordinary points.

After history deletion, the model can be edited in a standard way: existing objects can be deleted or edited (using available methods) and new objects can be created. If necessary, history of a construction can be deleted again.

You can cancel deletion of the construction history before you close the model's file.

Deletion of construction history is not available in models with variants. If necessary, you can save variants as individual models (see Section 2.13.3.7 on p. 771) and delete their construction histories.

2.15.10. Creation of Current Model Drawing

You can create drawing with an associative view of model (part or assembly) directly under the work with that model.

Model document should be saved into file on disk.

To create a drawing, call the **Operations — Create New Drawing from Model** command. After that a new drawing is automatically created, and the Default associated view in it. In this case, the current three-dimensional model is already selected as the model displayed in the view. Other view parameters are set by default (orientation — front, color — black, scale — 1:1, etc.). Modify the parameters if necessary.

Then select the position of the base point of view.

An arbitrary view will be created in the drawing depicting the current model.

The further work on the layout, i.e., creating other association views, formatting etc. is performed the same way as with a layout created in a regular manner.

2.15.11. Specifications

Specifications are a text included in the design document. Specifications compliment graphical information and ensure that the respective item is manufactured in strict compliance with the design idea.

In the model document, specifications are prescribed and displayed in a special window (see Section 2.15.11.2 on p. 843). You can transfer them in a model's associative drawing or save in a separate document, as well as print them.

After transferring to the drawing, specifications become part of it and can be edited or moved as needed (see Chapter 3.5.7 on p. 1198). At the same time, link is maintained between specifications in model and in drawing: if needed, changes in model specifications can be transferred to a drawing (see Section 3.6.3.9 on p. 1234).

2.15.11.1. Entering and deletion of specifications in a model

In order to enter specifications, call the **Specifications** command from the **View** menu or from the context menu of the Model Window. The **Specifications** window will appear on the screen. Enter text in the window (see Section 2.15.11.2 on p. 843).

In order to remove specifications from a model, delete the respective text in the **Specifications** window.

Specifications of components are not displayed in the assembly that contains them. You can view or modify specifications of a component in its edit mode **in window** or **at place**.

2.15.11.2. The Specifications window

You can use the **Specifications** window to work with specifications in a model.

This window is enabled or disabled using the **View – Specifications** command.

This window displays specifications if they are assigned to the model. The upper section of the window contains the menu of commands.

Fig. 2.15.17. **Specifications** window

You can perform the following actions in the **Specifications** window:

- ▼ enter and edit text,
- ▼ insert special objects and format text using commands from the **Insertion** and **Format** menus,
- ▼ format text using commands from the **Format** menu,
- ▼ save text in a separate text file (*.txt) or KOMPAS-3D text document (*.kdw) using the **Save in Document** command of the **File** menu,

- ▼ print text using the **Print** command from the **File** menu.

You can also edit text in the *mode of specifications handling* window. For this purpose, call the **Editor — Edit in window** command from the **Specifications** window menu. A window will appear on the screen displaying model's specifications in the edit mode.

This mode provides the same controls that are available when working with specifications entered in a drawing (see Section 3.5.7.1.1 on p. 1199). You can edit text, paste text fragments, check spelling in different languages and so on.

In the mode of *specifications handling*, text looks the same as it is when printed. When printed, line length depends on paper width. For more information about specifications printing, see Section 2.15.11.3 on p. 844.

Default text parameters are set up for new documents (see Section 9.2.7.9 on p. 1865). In the current document, settings can be adjusted when working with specifications. Text parameters set for model are not transferred to drawing.

In order to exit the *mode of specifications handling*, use special save and close commands in the **File** menu (see Table 3.5.11 on p. 1199).

To close the mode's window and return to the Model Window, you can also click the **Close** system button in the upper right corner of the window.

2.15.11.3. Printing specifications from model

Specifications in model are printed on sheets without layout. They can be printed using one of the following methods.

- ▼ The **Preview** command is used to print specifications together with the model's image. This command can be used for adjusting parameters in the preview mode and printing the document (see Chapter 8.2.1 on p. 1639). In the preview, specifications are displayed in separate sheets. You can adjust scale and other print parameters.
- ▼ When printing specifications without model, you can use the **Print** command which is called from the **Specifications** window or from the *mode of specifications handling* window (see Section 2.15.11.2 on p. 843).

2.15.12. Password for model access

You can protect access to model with a password. Since then, viewing and editing the model will only be possible as long as correct password is entered.

Assemblies (*.a3d) can be protected by entering password for assembly loading type(s). For more information about assembly loading, see Section 2.12.2.2 on p. 735; details about loading type passwords can be found in Section 2.12.2.3 on p. 741.

A **part** (*.m3d) model can be protected by entering password for access to the model. For this, do the following:

1. Highlight the root element (i.e. the part) in the Design Tree.
2. Call the context menu command **Access**.

3. In the appearing **Access to model** dialog, enter the password and a commentary (optional). Close the dialog by click the **OK** button.
4. In the next dialog, enter the password again and close the dialog by clicking the **OK** button.
5. Save the model file.

Password for access to a part, if there is any, will be requested in the following cases:

- ▼ opening of the part's file;
- ▼ insertion of the part into an assembly as a component;
- ▼ attempt to edit:
 - ▼ part — assembly component (using **Edit in window** and **Edit in place** commands);
 - ▼ base part (using the **Edit source** command);
 - ▼ part — image source in the associative view (using the **Edit in window** command).

In all of the above-mentioned cases, the dialog shown in Fig. 2.15.18 will appear. In order to load the model, password has to be entered in the respective field. If necessary, you can choose an access variant: edit or read only.

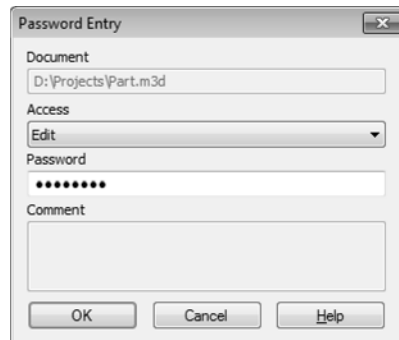

Fig. 2.15.18. Password entry dialog for access to a part's model

Changing and removing password procedures are similar to the password protection procedure. In order to change password, enter the new password in the **Access to model** dialog. If you want to remove password, delete all password symbols. Save the model's file after changing or removing password.

2.15.13. Layers in a model

A layer is a logical group of document's objects. Splitting a model into layers makes it simpler to change the properties of object groups. For example, you can show or hide all objects within a layer at once or transmit them into an associative view, etc.

The system layer is always present in models and, if no more layers had been created by the user, all objects are placed in the system layer.

You can create up to 2,147,483,647 layers in a model. Objects to be placed in a certain layer are selected by the user. Layers can contain objects of any type, including objects from different variants. However, one object cannot belong to two different layers.

To find out a layer where a certain object resides, select the object in the Design Tree or in the Model Window and choose **Object layer** from the shortcut menu. The layers of the selected object will be marked with a tick in the list of layers (see Fig. 2.15.22).

2.15.13.1. Layer statuses

The state of a layer is defined by the values of the following parameter values:

- ▼ This property *Visibility* controls displaying of a view and has two values: **visible** and **hidden**. If a layer is visible, its objects are displayed on the screen.
- ▼ *Color* — this property sets the color of the layer's objects on the screen. The layer color can be assigned in the standard color picker dialog.
- ▼ *Editability* — this property allows or prohibits the editing of the layer's objects and supports two values: **allowed** and **prohibited**.
- ▼ *Projectability into Drawing* — this property allows or prohibits projecting the layer and its objects into associative drawings and supports two values: **allowed** and **prohibited**.

To enable inheriting of the layer property value by the object property, the object property should be set to **By Layer**. For example, suppose that an object is located in *Layer 1*. To hide this object when *Layer 1* is also hidden and display it when *Layer 1* is also displayed, you should set the *Visibility* property of the object to **By Layer**. You can manage the object properties in the **Properties** window (see Section 2.14.3.6.1 on p. 793).

Only one of the layers has the **active (current)** status at a certain moment. The active layers is used for saving new objects.

Any layer can be made current. In this case, it automatically becomes visible. Active layers cannot be hidden until they have this status.

Layer's status and condition does not affect editing of objects. If an object's layer is hidden, the object should be highlighted in the Design Tree. Object editing does not result in any change of the respective layer's condition and status.

If necessary, model's objects can be moved from their layers to any other layer (see Section 2.15.13.6 on p. 850), including hidden ones.

The availability and output of the **Hide/Show** command for an object does not depend on the state of the layer where this object resides. However, note that when the *Visibility* property of an object was set to **By Layer**, then once you call the **Hide** command, it will be set to **Hidden** (and once you call the **Show** command, it will be set to **Visible**).

2.15.13.2. Layers in the Model Document Manager

The Document Manager is used for working with layers in a model. You can use it to perform the following actions:

- ▼ create and delete layers,
- ▼ select current layer,
- ▼ edit property values.

In order to open the Document Manager, perform one of the following actions:

- ▼ call the **Service — Document manager** command,

- ▼ click the **Document manager** button on the **Standard** panel.

- ▼ click the **Layer management** button in the **Current state** bar.

The **Document Manager** dialog for handling layers will appear (Fig. 2.15.19).

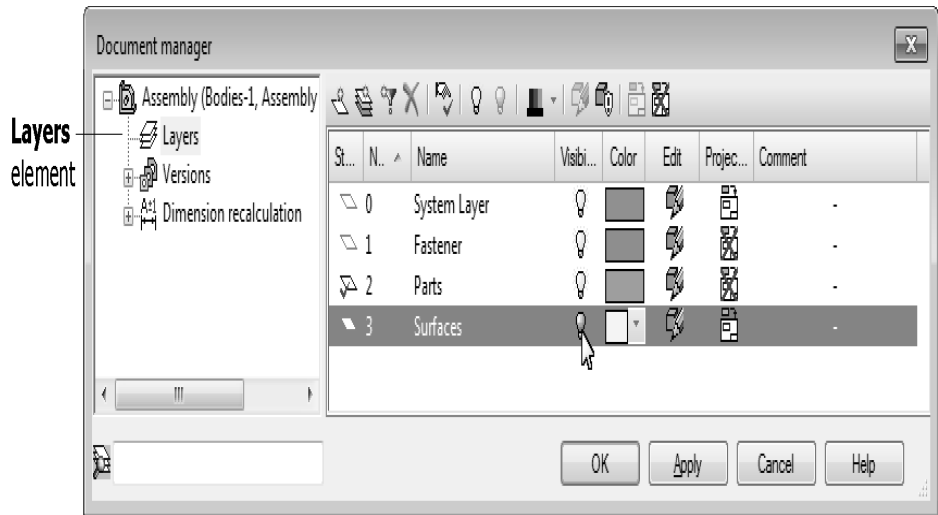

Fig. 2.15.19. Managing layers in the Model Document Manager

The first part of the dialog displays the document's Element Tree. If the dialog is called by the above-mentioned commands, the **Layers** element will be active in the Tree. At the same time, the right section of the dialog will display the list of layers created in the document and a toolbar for handling them.

The list of layers contains the names of layers created in the current model.

Values of the visibility property are displayed as icons in the fields of the List of Layers:

- ▼ *Status*;

- ▼ *Visibility*:

- ▼ visible layer,

- ▼ hidden layer;

- ▼ *color* — as a rectangle with the currently used color;

- ▼ *editability*:

- ▼ allow editing;

- ▼ prohibit editing;

- ▼ *project into drawing*:

- ▼ project into drawing,

- ▼ do not project into drawing.

The current layer is marked with a red check mark in the **Status** field.

An icon of an empty layer has different color than that of the layer with objects: it is gray in the former and blue in the latter.

Clicking a value in the **State**, **Visibility**, **Editing** and **Projection to drawing** field inverses it. Clicking the **Name** field allows modifying the value of the field. The object name can be changed by selecting **Rename** in its context menu. By clicking in the **Color** field, you can assign a color to the layer using the standard color picker.

You can alter the states of several layers at the same time in a similar manner. To do this, select them and then click the necessary button on the toolbar of the Document Manager or call the command from the contextual menu.

You cannot change `and editability` properties.

Objects, located in the List, can be sorted by any of the columns. To select a column for sorting, click on its name. A triangle will appear next to the name. It shows the direction of sorting. If the vertex of the triangle is faced down, then the sorting of the list is done by descending the values in this column, and if up— by ascending.

The toolbar is located in the upper part of the **Document manager** window. Its buttons are described in Table 2.15.4.

Tab. 2.15.4. Document Manager toolbar

The	Function
	Create Layer Create new layer.
	Create Group Create a group of layers.
	Create Filter Create new layer filter.
	Delete Delete selected layers. Deleting a layer means deletion of all objects located on it. Therefore, if you attempt to delete a non-empty layer, the object deletion dialog will appear on the screen. You can confirm deleting the layer with all its objects or cancel the deletion.
	Make current Makes the selected layer active.
	Visible Makes the selected layers visible.
	Hidden Hides the selected layers, i.e. makes them invisible.

Tab. 2.15.4. Document Manager toolbar

	The	Function
	Color	Change Color of Selected Layers. The layer color can be assigned in the standard color picker dialog.
	Enable Editing	Makes the selected layers visible.
	Disable Editing	Makes the selected layers visible.
	Transfer to the drawing	Make the selected layers projectable into an associative drawing.
	Do Not Project into Drawing	Make the selected layers non-projectable into an associative drawing.

The **Search Area** field is located under the Element Tree. This field makes it possible to search a layer by name or number.

In order to begin the search, enter a text line into the field. In this case, you can use masks. The “*” character used in masks replaces any arbitrary number of any characters. “?” character replaces any single character. The layers with names and numbers matching the specified line will be displayed in the List of Layers. The contents of the search area are not saved in the document.

2.15.13.3. Creating a layer in model

In order to create a new layer in model, perform the following operations.

1. Open the Document Manager using one of the above-mentioned methods (see Section 2.15.13.2 on p. 846). For example, lick the **Layer management** button in the **Current state** bar.

2. Click the **Create layer** button on the toolbar of the **Document Manager** dialog.

The new layer will appear in the List of layers. The text cursor will appear in the group name field. You can change the default name and add a commentary to the layer.

By default, a new layer is assigned the first unused number.

3. Set the state of the layer:
 - ▼ *visibility*,
 - ▼ *color*,
 - ▼ *editability*,
 - ▼ *projectability into associative drawing*.

Note that after creating a new layer, the current layer still remains the active one. If you need the new layer to be current, click the **Make Current** button or click the mouse on the **Status** cell. On the layer icon, a red “check mark” will appear, indicating that the layer is current.

4. After finishing entering all new layer parameters, click the **OK** button of the Document Manager.

2.15.13.4. Switching between layers

The current layer's name is displayed in the **Layer Management** field of the **Current State** bar.

The **Layer Management** field is displayed on the Bar, if it is positioned horizontally.

You can make any layer active, or make other layers visible/invisible using the **Document manager** (see Section 2.15.13.2 on p. 846).

However, the following method is the most convenient. Choose or enter using the keyboard the name of the required layer in the **Layer Management** field on the **Current State** bar, and the layer will become active (Fig. 2.15.20).

Fig. 2.15.20. Switching between layers on the **Current Status** bar

Objects of the layer selected in the list are highlighted in the Design Tree and in the Model Window. Icons in front of layers' names denote their visibility: *editability*, *visibility*, *color* and *projectability into associative drawing*. You can change the icon's status to the opposite one by clicking it. However, note that for the current layer, you can change only the *projectability into associative drawing* property.

2.15.13.5. Creating a layer in model

To select objects that reside in one or more layers within a model, choose **Select – By Layer**. The submenus with **By clicking** and **From list...** options will appear. These commands are similar to those in the graphical document, see Table 3.5.10 on p. 1192.

2.15.13.6. Moving model's objects between layers

In order to move objects to a certain layer, you can use the **Service – Modify Layer** command. The command can also be called from the context menu.

Once the command is called, control elements for setting layer modification parameters appear in the Property Bar.

Specify the objects that need to be moved to another layer. You can specify components, bodies, surfaces, curves, points, dimensions, designations, sketches, local coordinate systems, and others. Exceptions are axes and planes of the absolute coordinate system which can only be positioned in the system layer.

Operations are not objects that can be moved to layers separately from bodies containing them.

Selected objects are highlighted in the model. Names of objects and their layers are displayed in the **List of Objects** bar (Fig. 2.15.21).

In order to delete an object from the list, highlight the row and click the **Delete** button above the list. To cancel object selection in the model, re-select it.

Objects can be selected before calling the command.

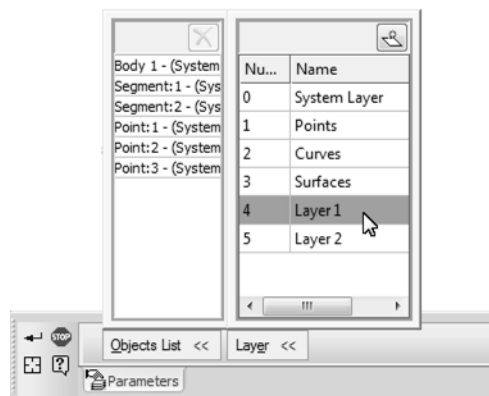

Fig. 2.15.21. Transmitting Objects to Another Layer

In the **Layer** bar, specify the layer to which selected objects have to be moved. For this purpose, click the row with the layer's name.

In order to create a new layer, click the **Create new layer** button above the list.

Once the objects are specified, click the **Create object** button in order to move them to the selected layer.

You can also change a single object's layer by doing the following. Call the **Object Layer** command from its context menu. The command menu contains the system layer and user layers, while the current object's layer is marked with a tick. Specify the required layer in the menu in order to change it (Fig. 2.15.22).

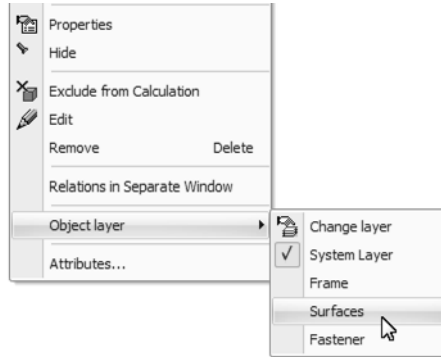

Fig. 2.15.22. Choosing a layer from the **Object Layer** command menu

The value of the property of the object within a layer will be the same as the value of the layer's property, if the object's property is set to **By Layer** in the **Properties** window (see Section 1.4.2.2 on p. 82).

2.15.13.7. Removing a layer from a model

You can delete a layer from the document. Objects positioned on the layer will also be deleted. In order to delete a layer, do the following.

1. Open the Document Manager using one of the above-mentioned methods (see Section 2.15.13.2 on p. 846). For example, lick the **Layer management** button in the **Current state** bar.

2. Select the layers that should be deleted in the List of Layers.

If you know the name of the layer, it can be selected using the Search area located in the lower left corner of the Document manager.

3. Click the **Delete** button on the Document Manager toolbar.

You can delete neither the current nor a system layer.

If the layer being removed contains objects, a dialog will appear on the screen making it possible to view them and confirm deletion, or cancel it.

4. Confirm the deletion.
5. Close the dialog Document Manager by clicking the **OK** button.

When you delete a layer projected into an associative drawing in a document, the layer is also removed from the drawing. If the layer you are deleting contains any non-projective objects, then they are automatically copied to the system layer of the drawing.

2.15.13.8. Layer Groups and Filters in a Model

The purpose of layer groups and filters as well as their workflows are almost the same as in the graphical document. This section briefly describes how to create and remove layer groups and filters in a model. For more details, refer to Section 3.5.6.9 on p. 1192 which describes the sets of layers in a graphical document (in a graphical document, sets of layers include the following: layer groups, layer properties groups and layer filters; models do not support layer properties groups).

To create a layer group in a model, click the **Create Group** button on the toolbar in **Document Manager** (see Fig. 2.15.19). An icon for a new group will appear in the Design Tree.

Drag the layers you want to the icon of the created group.

To create a layer filter in a document, click the **Create Filter** button on the toolbar. After that, the **Layers Filter** dialog will be displayed (Fig. 2.15.23). In the **Conditions** table of this dialog, specify one or more filtering conditions for layers. You can check the results in the **Preview** table.

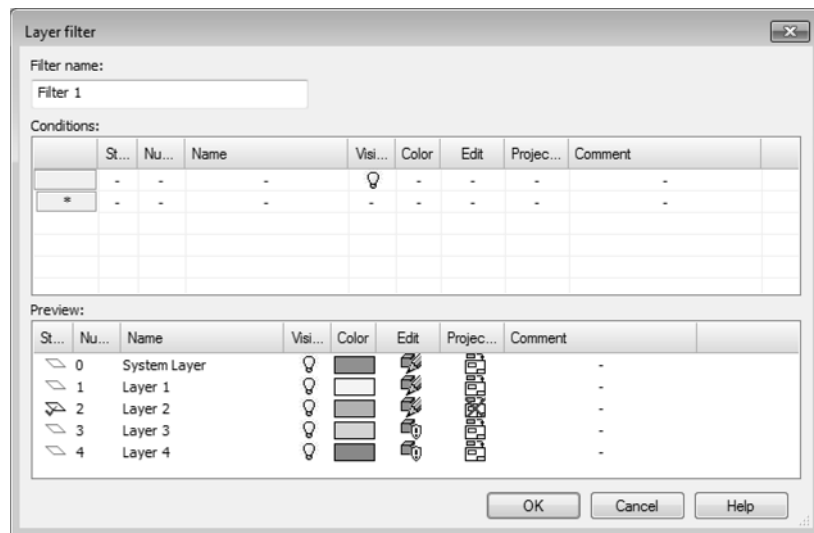

Fig. 2.15.23. The create layer filter dialog for the document model

To finish configuring a filter and close the dialog, click **OK**. The filter icon will appear in the Tree of the Document Manager.

To remove a layer group or a filter, select them in the Tree in Document Manager and click **Delete** or choose the corresponding command from the shortcut menu.

Filters can be converted into groups (see Section *Converting a filter into a group* on p. 1197).

2.15.14. Zones in a Model

You can create zones in a model. Zone is a selected space within the volume of the model.

Zones are useful in models which contain lots of components split into relatively small groups. Using zones, you will be able to select object groups in such models more quickly. For details

on selecting objects using zones, see Section 2.15.14.4 on p. 858.

You can split a zone into multiple zones. The resulting zones, in turn, can also be split into zones, and so on.

You can display or hide zones in the model window by choosing **View – Display – Show Zones** or by clicking the **Display Zones** on the **View** toolbar.

All zones available in the model are listed on the **Zones** tab in the Model Tree (see Section 2.15.14.1 on p. 854). When this tab is active, the zones are displayed in the model window independently of their visibility settings.

Zones are shown in the model as semi-transparent polyhedrons. You can set the zone visibility parameters for the current window using the special dialog (see Section 9.3.4 on p. 1867).

When you create zones in the variant models, they are transmitted just like any other objects (see Section 2.13.3.2 on p. 761).

2.15.14.1. Zone Tree

The zone tree is displayed on the **Zones** tab of the Model Tree (Fig. 2.15.24). The tree displays the zones and splittings starting from the oldest ones.

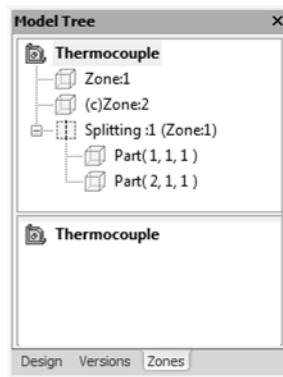

Fig. 2.15.24. Model Zones Tree

Zones and splittings are shown at the first level of hierarchy in the Tree.

The subzones derived from splittings the zones are shown at the second level.

The zones and splittings are automatically assigned the names and numbers during creation.

Letter 's' in parenthesis precedes each system recalculation. To make another zone the current one, select it in the Zone Tree and choose **Current Zone** from its shortcut menu. Upon calling the command, a “tick” appears beside its name in the menu.

To hide the assembly components, highlight them in the model's Tree and call the **Hide** or **Show** command in the contextual menu.

To remove a zone or a splitting, select the required object in the Zone Tree and choose **Delete** from the shortcut menu.

2.15.14.2. Creating a Zone in a Model

A zone is an object that uses coordinate system (for object coordinate system, refer to Section 2.8.3.4.1 on p. 598).

You can set the zone dimensions in a model in the following ways:

- ▼ **By coordinates;**
- ▼ **By object dimensions.**

For your convenience, you can display the zones in the model window or choose the **Zones** tab in the Model Tree.

Call the **Create Zone** command in one of the following ways:

- ▼ from the **Editor — Zones** menu,
-  ▼ by clicking the corresponding button on the **Construction Geometry** toolbar,
- ▼ from the shortcut menu of a part or an assembly on the **Zones** tab.

Once you call the command, the **Parameters** tab on the Properties panel will display the controls for adjusting the zone parameters, see Fig. 2.15.25.

Fig. 2.15.25. Properties panel during creation of a zone

From the **Method** drop-down list, choose how to set the zone dimensions and specify the required parameters. Parameter input for each method is detailed in Sections 2.15.14.2.1 on p. 855 — 2.15.14.2.2 on p. 856.

You can specify the objects for setting the zone dimensions in the Design Tree or in the Model Window before calling the command. In this case, the Properties panel will display the controls for **By object dimensions** by default.

On the **Properties** tab of the Properties panel, you can change the default name of any zone. This tab also displays the name of the curve coordinate system.

This tab also displays the name of the zone coordinate system.

To set other parameters of the zone without leaving the command, click **Select other** on the Advanced Control Panel.

To finish building, click **Create object** button.

The created zone will appear in the model window while its icon and name will appear in the Model Zone Tree.

2.15.14.2.1. Creating a Zone by Coordinates

To set the zone dimensions using the **By coordinates** method, perform the following actions:

1. Choose the box definition type. To do this, enable one of the following switches in the **Option** group:
 - ▼ **By two vertices,**

▼ By center and vertex,

2. Position parallelepiped points.

The position of the first point is set when the **Point 1** switch is active and that of the second one — when the **Point 2** switch is active.

Point coordinates can be input from a keyboard or defined automatically by positioning the point with the mouse in the model window or selecting a point object. These operations are similar to those described in Section 2.5.2.2 on p. 336.

You can also specify the coordinates using the point construction process which can be launched by clicking the **Point Creation** button on the Advanced Control Panel (see Section 2.5.2.11.1 on p. 347). The parameters set during this process define the position of the box point. No new point is created in the process.

2.15.14.2.2. Creating a Zone by Object Dimensions

To set the zone dimensions using the **By object dimensions** method, specify the objects which define the zone dimensions.

The objects can be selected either in the Model window or in the Design Tree. The specified objects are highlighted, and their names appear in the **List of objects Bar**.

The auxiliary planes and axes are not used for defining the zone dimensions.

To delete any object from the list, highlight it and press the **Delete** button, located above the list.

Second selection of the base surface cancels its selection.

The zone looks like a box which covers all the objects you've specified.

When choosing objects in the Design Tree, you can specify either the entire model or any of its components. In this case, the default zone dimensions are defined by the bodies and surfaces included in the model or its component. During the configuration process, you can change the list of objects which define the zone dimensions (see Section 9.2.7.4.14 on p. 1858).

The lists of object types for the model and its components may be different. In this case, the zone dimensions for a model are defined only by the objects included into all these lists. If a zone dimension does not take into account some types of objects when you select the component, this means that they were excluded from the list during configuration process for this component. You can set the required components manually when required.

When the **Specify Parts** button is pressed on the Advanced Control Panel, you can select individual parts at any assembly level. When this button is released, then when you select a part, the entire component of the first level to which this part belongs is selected.

2.15.14.3. Splitting into Zones

You can split a zone into subzones in the following ways:

▼ Uniformly along axes;

▼ By set of planes.

For your convenience, you can display the zones in the model window or choose the **Zones** tab in the Model Tree.

To split a zone, choose **Editor — Zones — Split Zone** or click the corresponding button on the **Construction Geometry** toolbar.

Once the command is called, control elements for setting the zone splitting parameters appear in the Properties panel (see Fig. 2.15.26).

Fig. 2.15.26. Properties panel when splitting a zone

Specify the sketch in the Model Tree or Window.

On the Properties panel, select the zone splitting method and set the required parameters in the **Splitting Method** group of switches.

Parameter input and object specification for each method is detailed in Sections 2.15.14.3.1 on p. 857— 2.15.14.3.2 on p. 857.

Once you've specified the parameters, the model window will display the ghosts of the new zones in the zone being split.

On the **Properties** tab, you can change the default name of the splitting.

To set other splitting parameters of the zone without leaving the command, click **Select other** on the Advanced Control Panel.

You can create a new zone in the model without leaving the command. To do this, click the **Create zone** button on the Advanced Control Panel.

To finish building, click the **Create object** button.

The new zones will be displayed inside the zone being split.

The names of the splitting and new zones are shown in the Model Zone Tree.

A single zone can contain multiple splittings.

2.15.14.3.1. Splitting a Zone by Axes Equally

To split a zone using the **Equally by axes**, specify the values you want in the **Number of Zones by X**, **Number of Zones by Y** and **Number of Zones by Z**.

The number of zones on at least one of axes must be greater than 1.

2.15.14.3.2. Splitting a Zone by A Set of Planes

To split a zone using the **By set of planes**, specify the planes which will divide the zone. The planes must intersect with the zone you want to split. The following can be used as a plane:

- ▼ coordinate and auxiliary planes,
- ▼ flat faces.

The planes can be selected either in the Model window or in the Design Tree. The specified objects are highlighted, and their names appear in the **List of objects**. Bar.

To delete any object from the list, highlight it and press the **Delete** button, located above the list.

Second selection of the base surface cancels its selection.

2.15.14.4. Selecting Objects Using Zones

To select objects using a zone, perform the following actions.

1. Display the zones in the model window or choose the **Zones** tab in the Model Tree.
2. Specify the required object in the Design Tree or Model Window.
3. Choose the required zone from the **Select — By zone** menu or from the context menu:

- ▼ **Select Inside a Zone** — choose the objects within a zone, including the tangential ones.
- ▼ **Select Outside a Zone** — choose the objects outside a zone, including the tangential ones.
- ▼ **Select with a Section Zone** — choose the objects inside the zone as well as objects intersecting the borders of the zone.

If no zone is selected when running the command, then the command is applied to the current zone.

When selecting by zone, the object filters are taken into account (see Section 2.1.4.1.3 on p. 133).

You can use the object group selection by zones to apply the certain commands to all the selected objects at once, e.g. change the loading type (for details on loading types, see Section 2.12.2.1.6 on p. 733).

After running any of the selection command, the list of selected objects is displayed in the lower part of the Zone Tree. When you call a command from the shortcut menu of any object in the list, the command is applied to all objects at once. For example, when you call the **Loading types** command and specify a certain loading type, this type will be applied to the entire object group.

You can use selection by zones either at the level of the current document or at all levels (this can be configured, see Section 9.1.11.14 on p. 1738). In the first case, the system checks whether the components of the model are included in the zone, and in the second case, the system checks object by object. Therefore, in the first case you can choose only the entire components while in the second case you can select individual objects within them.

2.16. Technological preparation of a model

2.16.1. Technological assembly

KOMPAS-3D makes it possible for the user to prepare a model (part or assembly) for the development of the technological process of its manufacturing (or assembly). For this purpose, the technological assembly is used.

The **Technological assembly** is a 3D model that contains technological data, for example, the result of model size recalculation taking account of tolerances, technological objects (center holes, mounting holes, and so on), technological models (lunettes, centers, instruments, and other equipment). The technological assembly is created and saved in a Technological Assembly file with the *t3d* extension.

Examples of using the technological assembly:

Example 1

A part has been created by the designer. In order to develop the technological process of the part's manufacturing, the technologist creates the technological assembly, incorporates the part in it, and adds the required technological data.

Example 2

The general gear box assembly has been created by the designer. Two cases of the gear box should be processed together. Models of the cases are located in different subassemblies of the gear box's general assembly. The technologist creates the technological assembly and incorporates the gear box's cases in it. Then, the technologist adds technological data to the assembly that is required for joint processing of the cases.

The technological assembly may contain any objects that can be part of an ordinary KOMPAS-3D assembly (see Section 2.1.1.1 on p. 99).

Working with technological assembly (adding components, creation and editing of bodies and surfaces, creation of mates and so on) is similar to working with ordinary assembly.

Some toolbars in the technological assembly are disabled by default (for example, the **Arrays** bar).

The following procedure for creating a technological assembly is recommended.

1. Create the new technological assembly document.
2. Add the required components (created previously by the designer of a part and/or assembly).
3. If necessary:
 - ▼ edit the model by performing operations in the technological assembly,
 - ▼ recalculate dimensions of the model based on tolerances;
 - ▼ add:
 - ▼ technological models and standard items in the form of components,
 - ▼ technological data.

If, when working with the technological assembly, the assembly's contents should be changed, it is recommended to fix its components. For this purpose, you can highlight the *Components* section in the Design Tree and click the **Enable fixation** button on the **Edit assembly** bar.

Component changes performed by operations in the technological assembly are not transferred to the component's file. These changes are saved in the technological assembly. At the same time, all changes in the model, made during modifications of the model file, will be transferred to the technological assembly.

If the technological assembly is created on the basis of an ordinary assembly using the **Save as...** command, all other changes of the initial assembly will not be transferred to the technological assembly.

By default, components are added to the technological assembly with nominal dimensions. You can change dimensions of each component in the assembly taking account of tolerances assigned by the designer to the component's dimensions (dimensions of sketches and dimensions corresponding to parameters of operations; see Section 2.9.2.2 on p. 632). More information about managing the dimensions of a component in an assembly can be found in Section 2.16.2 on p. 860.

2.16.2. Taking account of tolerances when controlling dimensions of a component

By default, components are added to the model with nominal dimensions. If necessary, you can recalculate the dimensions of a component taking account of assigned tolerances (see section 2.10.2 on p. 667 for more information about tolerances). Dimensions of a component are calculated in accordance with the current recalculation.

KOMPAS-3D supports three system recalculations of dimensions: **to middle part of the tolerance field**, **by upper limit** and **by lower limit**. The component can also have **custom** recalculations creating in the process of its editing. For more information on recalculations of dimensions, see Section 2.10.3.1 on p. 672.

You can control dimensions of a component taking into account the tolerances after the component has been inserted.

You can adjust recalculation of dimensions only for components of the first level (i.e. for a component inserted directly in the current model). Defined parameters of recalculation of a component's dimensions are applied to dimensions of all objects included in it.

2.16.2.1. Recalculation of a component's dimensions within an assembly

Recalculation of a component's dimensions in an assembly is initiated by the **Component properties** command. The command is available in the context menu of the component selected in the model window or in the Design Tree.

When the command is called, the pages containing control elements for component properties setup will be displayed on the Property bar.

In order to modify the component's dimensions in accordance with the required recalculation, click the **Recalculate Dimensions** button on the **Source File** tab. A list of recalculations will become available (see Section 2.10.3.1 on p. 672). Choose the required recalculation from the list – a system recalculation or a user one (Fig. 2.16.1).

Fig. 2.16.1. Selection of a component's dimensions recalculation

Note that only system recalculations are available for a local part.

Having finished selection of a recalculation, click the **Create object** button on the Advanced Control Panel.

The icon of the edited component image will be marked in the Design Tree by a red “check-mark” which means the assembly needs to be rebuilt.

In order to see how the assembly looks like with modified parameters of the component, click the **Rebuild** button in the **View** bar or call the **View – Rebuild** command.

In the Design Tree, the recalculated component is marked with letter “r” in parentheses.

2.16.2.2. Restoring nominal dimensions of component.

To restore nominal dimensions of the component that was inserted into a model, take the following steps.

1. From the component's context menu, call the **Component properties** command.

2. In the **Source File** tab, disable the **Recalculate Dimensions** button. The list of recalculations will become unavailable.

3. In the Special Control bar, click the **Create Object** button.

4. Rebuild the model. For this purpose, click the **Rebuild** button on the **View** bar or call the **View – Rebuild** command.

3. Drawing. Drawing Layouts

3.1. General working techniques for graphical documents

3.1.1. Snaps

3.1.1.1. General Information on Snaps

While working with a graphic document, you constantly experience the need to place the cursor precisely at a specific point (a coordinate system origin, a circle center, a segment end, etc.), in other words, to snap to existing points or objects. Without such a snap, you cannot create a precise drawing.

KOMPAS-3D offers snaps to **defining points** (intersection, border points, center, etc.) and **objects** (by normal, by coordinate axes directions).

Snaps can be made by means of the keyboard (keyboard snap) or using special commands. Keyboard snap is available any time while command-based snap is only available when creating or editing graphical objects.

Command-based snap may be attributed **globally** (global snap) or **locally** (local snap).

The global snap (if enabled) works always as you create and edit objects. For example, if the global snap to intersections is enabled, then when creating each point, the system will automatically search for the nearest intersection within the reach of the cursor's catcher.

Local snap has a single time effect. For example, if the local snap to intersections is enabled while creating a point, then after completing creation of that point the snap stops working. To make the same snap when creating the next point, it should be re-enabled. This is inconvenient to use local snap if you need to make several similar snaps in a row.

Local snap has higher priority than the global one, i.e. global snaps enabled in the window have no effect when local snap is in effect.

List of keyboard snap shortcuts is presented in Section 3.1.1.3 on p. 870, list of global and local snap commands— in Section 3.1.1.2.

3.1.1.2. Global and Local Snap

List of global and local snap commands used in KOMPAS-3D is shown in Table 3.1.1.

Tab. 3.1.1. Global and Local Snap commands

Name	Description
Nearest Point	Snap to a defining point of an object (e.g., the start point of a line) or the origin of the current coordinate system.
Midpoint	Snap to the midpoint of an object.
Intersection	Snap to the intersection of objects.

Tab. 3.1.1. Global and Local Snap commands

Name	Description
Tangency	When selecting this method, the snap will be performed in such a way that the created object (line segment, arc, etc.) touches the specified object in the point nearest to the current cursor position.
Normal	When selecting this method, the snap will be performed in such a way that the object being created (such as a line segment) will be positioned perpendicular to the specified object.
By Grid	Snap to a point in the construction grid (see Section 3.1.4.1 on p. 885) in the current window (the grid may be enabled or disabled).
Alignment	When you select this snap method, the entered object point will be aligned vertically and horizontally relative to the defining points of the existing objects and the last fixed point. Alignment is done without respect to the slope angle of the local coordinate system.
Angular Snap	When selecting this snap method, the cursor will move at an angle to the last fixed point, which is a multiple of the value defined among the snap settings (see Fig.3.1.3). The angles are measured in the current coordinate system. By default, the angular snap step is equal to 45°.
Centerpoint	Snap to the center point of a circle, ellipse, circular or elliptic arc, rectangle, regular polygon.
Point on Line	Snap to the nearest point on the selected curve. The nearest point will be determined as an intersection of the curve with a normal drawn from the specified point.

The snap is done as follows.

During the graphical object creating and editing set the cursor so that its catcher reaches to the object (or point), which you need to snap to (Fig.3.1.1). For example, to use **Nearest Point** snap, you have to capture a defining point of any object (a few examples of defining points are shown on Fig.3.4.2 on p. 1115); to use **Center** snap— an arc, polygon, or different object with a center point.

A “cross” will appear at the point corresponding to the snap, which means the snap has been activated (Fig.3.1.1).

When using global snaps, the only one snap with the highest priority will be enabled (see Section 3.1.1.2.1).

To finish the snap press the <Enter> key or the left mouse button. The point marked by a “cross” will be fixed.

Fig. 3.1.1. Using the **Center** snap to specify the hole center

You can change the size of the cursor's catcher by calling the **Service — Parameters... — System — Graphic Editor — Cursor** command (see Section 9.1.7.1 on p. 1703).

3.1.1.2.1. Using Global Snaps

To manage global snaps, use the **Snaps** button menu in the **Current Status** tab. To enable a desired snap in the current window, call the relevant menu command.

To enable snaps you can also use **Global Snaps** bar buttons. While the button is in depressed state, the snap will be working. To disable a snap, release the button.

Fig. 3.1.2. Global snaps bar

You can turn on several different global snaps to objects, and all of them will work simultaneously. In this case, the point is calculated “on-the-fly”, and a ghost is displayed that corresponds to this point.

If several snaps can be enabled in the current cursor position, the one with the highest priority will be enabled. The list of priorities coincides with the order of listing the snaps in their setup dialog (Fig. 3.1.3).

Suppose that the snaps **Nearest Point** and **Intersection**, which follow one after another in the list, are activated. If in the current cursor position (for example, when selecting a point for alignment) its “catcher” reaches to a defining point of an object and an intersection point of objects, then the higher-priority **Nearest Point** snap will become activated.

The snaps **Orthogonal**, **Align** and **Point on Curve** (if enabled) can be activated in couples. For example, the combined use of the **Align** and **Point on Curve** snaps allows fixing a point on a curve with the same X or Y axis as the defining point of any object.

You can disable all global snaps and then re-enable them by clicking the **Snaps** button. The Disable Snaps button serves as an indicator of enabled global snaps: the pressed button means the global snaps are enabled, the released button means they are disabled. To switch the button from the keyboard, use the key combination **<Ctrl>+<D>**. To temporarily disable global snaps, press and hold the **<Alt>** key; once the key has been released, the snaps will be enabled.

Enabling and disabling of the global snaps as well as a number of additional settings are available in the global snap setup dialog (Fig.3.1.3). You can open it by clicking the **Set Global Snaps** button on the Current Status bar.

The control elements of this dialog are described in Section 9.1.7.16 on p. 1717.

Fig. 3.1.3. Global snap setup dialog

Note that enabling and disabling of the global snaps using described above methods will be active only in the current window till the end of the current working session.

If a document is open in several windows, then the snap settings made in one of them affect all other windows of this document.

The default setting of global snaps — the one used in the windows of newly created or open documents — will remain unchanged. In order to change it, call the **Service — Parameters...** command. — **System— Graphic Editor— Snaps** command. A dialog shall appear, with controls identical to those shown in Fig. 3.1.3 (the only exception is the absence of the **Disable Snaps** option), where you can enter the required settings.

3.1.1.2.2. Local Snap use

A local snap enabling is possible while you create and edit graphic objects. The commands for enabling local snaps are grouped together in the menu. There are two ways to access this menu.

1. Using the context menu (Fig. 3.1.4).

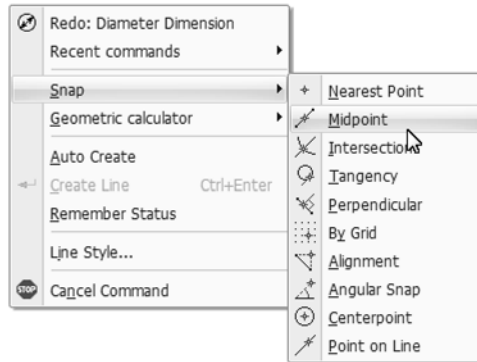

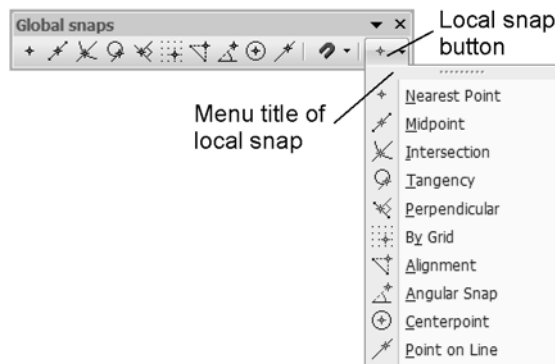

Fig. 3.1.4. Commands for enabling local snaps in the context menu

- Using the **Local Snaps** button. This is the button of the last used local snap on the **Global Snaps** bar (Fig. 3.1.5).

Fig. 3.1.5. Menu of the **Local Snaps** button

The commands in the **Local snaps** button's menu can be placed as buttons on a separate bar, and then move this bar to any convenient location. To do this, drag the **Local Snaps** menu button by its title in any direction.

The **Local Snaps** toolbar will be created. Note the difference of the Orientation bar from other toolbars: you cannot change the composition or the order of buttons on them.

To enable local snap needed call the corresponding menu command or press the button on the **Local Snaps** bar.

Cursor will change its shape, indicating that the snap is active. All global snaps will be suspended until the current operation is finished.

The **Local snaps** button on the **Global snaps** bar is available after calling the object creation or editing command.

3.1.1.3. Keyboard Snaps

Some snaps can be activated using the keyboard by pressing the corresponding keyboard shortcuts. These commands are shown in the Table 3.1.2.

Keys <0>–<9> and <.> have to be pressed on the additional keypad. The keypad has to be in numeric mode (the NumLock indicator has to be on).

Tab. 3.1.2. Snap shortcuts

Combination	Description
<Ctrl>+<0>	Move the cursor to the (0,0) point of the current coordinate system.
<Ctrl>+<5>	Position the cursor in the element defining point nearest to it, independently on what is on Background Views and Layers*
<Ctrl>+<Shift>+<5>	Position the cursor in the element defining point nearest to it, including what is on Background Views and Layers.
<Ctrl>+<.>	Position the cursor normal to the nearest point of the nearest element.
<Alt>+<5>	Position the cursor at the nearest to it point of two entities intersection.
<Shift>+<5>	Position the cursor at the nearest to it mid-entity.
<Ctrl>+<1>	Snapping to the nearest element along the diagonal between the negative direction of the OX axis and the negative direction of the OY axis of the current coordinate system.
<Ctrl>+<2>, <Ctrl>+<⤴>	Snapping to the nearest element in the opposite direction of the OY axis of the current coordinate system.
<Ctrl>+<3>	Snapping to the nearest element along the diagonal between the positive direction of the OX axis and the negative direction of the OY axis of the current coordinate system.
<Ctrl>+<4>, <Ctrl>+<⤵>	Snapping to the nearest element along the opposite direction of the OX axis of the current coordinate system.
<Ctrl>+<6>, <Ctrl>+<⤶>	Snapping to nearest element in the positive direction of the OX axis of the current coordinate system.
<Ctrl>+<7>	Snapping to the nearest element along the diagonal between the negative direction of the OX axis and the positive direction of the OY axis of the current coordinate system.
<Ctrl>+<8>, <Ctrl>+<⤷>	Snapping to the nearest element in the positive direction of the OY axis of the current coordinate system.

Tab. 3.1.2. Snap shortcuts

Combination	Description
<Ctrl>+<9>	Snapping to the nearest element along the diagonal between the positive direction of the OX axis and the positive direction of the OY axis of the current coordinate system.

* This key combination is also available when the NumLock mode is disabled. In this case, it serves to position the cursor in the element defining point nearest to it, including what is on Background Views and Layers

3.1.2. Geometric Calculator

One of the ways to specify numerical parameters of graphic objects is to copy the parameters of existing objects. To do this, use the so-called **Geometric Calculator**.

The geometric calculator commands are available in the context menu after you enter a numeric parameter if the **text cursor is not located** in this field. The set of commands depends on the parameter type (see Table). 3.1.3 on p. 874).

After executing the Geometric calculator command, you should specify the object(s), whose parameters you want to obtain: locate the cursor so that it's "trap" captures the required object and press the <Enter> key or left-click the mouse.

In order to change the cursor's "catcher" size, use the **Service — Parameters... — System — Graphic Editor — Cursor** command.

The Properties bar changes while the geometric calculator is in use. All tabs on the Properties bar are replaced with a single bar whose name corresponds to the selected command of the geometric calculator, and the **Interrupt Command** and **Help** buttons remain on the special control panel. They allow canceling the geometric calculator or receiving advice on the current geometric calculator command, respectively.

Let us consider ellipse construction as an application example of the geometric calculator, with ellipse center being at the point of intersection of line segment extensions, it's axis parallel to one of the segments, and it's semi-axis equal to the arc length (Fig. 3.1.6).

Fig. 3.1.6. Objects, the parameters of which shall be used by the Geometric calculator

Create a new graphic document and construct the objects shown in Fig. 3.1.6, trying to visually maintain the proportions. Then, complete the following actions.

1. Click **Tools — Geometry — Ellipses — Ellipse** command.

Fields will appear on the Properties bar for entering the ellipse parameters — center coordinates, semi-axes end coordinates, semi-axes lengths, and the slope angle of the first semi-axis (Fig. 3.1.7).

Fig. 3.1.7. Property bar when creating a line segment

2. Open the context menu in the coordinate field of the ellipse center. This menu contains geometric calculator commands for specifying the point location (Fig. 3.1.8).
3. Call **At Intersection of Curve Extensions** command from this menu.

Fig. 3.1.8. Geometric calculator menu when specifying the point

The **Ellipse** tab on the Properties bar shall be replaced with the **At Intersection of Curve Extensions** tab.

4. Select with the cursor the line segments, at the extensions of which the ellipse center should be created. The intersection point of line segment extensions is built automatically.

The **Ellipse** tab will appear on the Properties bar again.

The point coordinate value will be calculated, entered in the **Center** field and fixed.

5. Open the context menu in the field of the slope angle of the first ellipse axis. This menu contains geometric calculator commands for specifying lengths (Fig. 3.1.9).

Fig. 3.1.9. Geometric calculator menu when specifying the angle

6. In this menu, call the **Line Direction** command and proceed to specify the line parallel to which the first ellipse axis should be.

The slope angle value of this line relative to the OX axis of the current coordinate system will be calculated, entered in the **Angle** field and fixed.

7. Open the context menu in the field of the first ellipse axis length. This menu contains geometric calculator commands for specifying lengths (Fig.3.1.10).

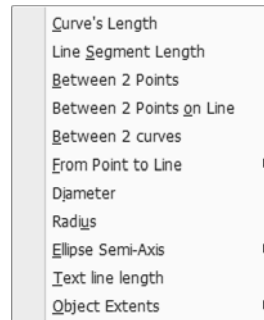

Fig. 3.1.10. Geometric Calculator menu

8. In this menu, call the **Line Length** command and proceed to select the arc to which the ellipse semi-axis length should be equal.

The length value will be calculated, entered in the **Length 1** field and fixed.

9. Specify the length of the second semi-axis on your own.

At this point, the construction of the ellipse with the specified parameters is complete (Fig. 3.1.11).

Fig. 3.1.11. Ellipse construction result

If the value was fixed before you executed the geometric calculator command, a new value will be entered in the parameter field by the calculator and the fixation will be preserved.

When specifying coordinates during object creation (for example, when defining the start and end points of a line segment), you can call the Geometric calculator commands for point creation (fig.3.1.8 on p. 872) not only from the context menu for coordinate fields of this point, but also from the context menu of a document window.

Tab. 3.1.3. Geometric calculator commands

Command	Purpose
When entering coordinate values	
At Intersection of Curve Extensions	Obtaining coordinate values of the point located at the intersection of extensions of the specified elements.
At Distance from Point	Obtaining coordinate values of the point located at the preset distance from the reference point.
At Distances from Two Curves	Obtaining coordinate values of the point located at the preset distances from specified elements.
Align by Two Points	Obtaining coordinate values of the point aligned by two points. The point is considered to be aligned by two other points if they are the point's projections on the current coordinate system axis.
Intersection Notation	Obtaining coordinate values of the point located at the intersection of extensions of the specified elements with intersection notation construction. For details about intersection notation see Section 3.3.12.19 on p. 1065.
Curve's Point, Nearest to Another Curve	Snapping and obtaining coordinate values of the point located on the specified element and nearest to another specified element.
When entering linear values	
Line Length	Copying the length (perimeter) value of the selected element.
Line Segment Length	Copying the length value of a polyline or layout segment as well as a polygon side.
Between Two Points	Serves to read the distance between two selected points.
Between Two Points On Line	Copying the length of a curve section limited by two points selected on this curve.
Between Two Lines	Copying the value of the minimum distance between two selected objects.
From Point to a curve — By Normal	Copying the value of the shortest distance between the selected point and the curve.
From Point to a curve — Along Y	Copying the value of the distance between the selected point and object in the positive direction of the Y axis of the current coordinate system.

Tab. 3.1.3. Geometric calculator commands

Command	Purpose
From Point to a curve — Against Y	Copying the value of the distance between the selected point and object in the negative direction of the Y axis of the current coordinate system.
From Point to a curve — Along X	Copying the value of the distance between the selected point and object in the positive direction of the X axis of the current coordinate system.
From Point to a curve — Against X	Copying the value of the distance between the selected point and object in the negative direction of the X axis of the current coordinate system.
Diameter	Copying the diameter value of the selected circle or arc.
Radius	Copying the radius value of the selected circle or arc.
Ellipse Semi-axis— Major	Copying the length of the major semi-axis of the selected ellipse.
Ellipse Semi-axis— Minor	Copying the length of the minor semi-axis of the selected ellipse.
Text Line Length	Copying the length of the selected text line.
Object Extents— Horizontal	Copying the value of the horizontal dimension of the selected object.
Object Extents— Vertical	Copying the value of the vertical dimension of the selected object.
When entering angular values	
Line Direction	Serves to read the angle between an infinite line or segment and the positive direction of the X axis of the current coordinate system.
Tangent Slope	Copying the value of the angle between the tangent to a selected element passing through the selected point on this element and the positive direction of the X axis of the current coordinate system.
Normal Slope	Serves to read the angle between the normal to an element going through a specified point on that element and the positive direction of the X axis of the current coordinate system.
Included Angle	Copying the included angle value of the selected circular arc.
Between Lines	Copying the value of the angle between two selected lines.
Slope of the Ellipse Axis	Serves to read the angle between the major axis of the specified ellipse and the positive direction of the X axis of the current coordinate system.

Tab. 3.1.3. Geometric calculator commands

Command	Purpose
By Two Points (with the X Axis)	Serves to read the angle between the imaginary line going through two specified points and the positive direction of the X axis of the current coordinate system.
By three Points	Copying the value of an angle formed by three selected points. Selection procedure: angle vertex, points on its sides.
Text Line Direction	Serves to read the angle between the line of text and the positive direction of the X axis of the current coordinate system.
By Point on Circle/ Arc	Serves to read the angle between the radius constructed from the circle center to a specified point on the circle and the positive direction of the X axis of the current coordinate system.

3.1.3. Selection of Objects. Using the Clipboard

3.1.3.1. Selecting Objects with the Mouse

To select items by the mouse, complete the following steps.

1. Move the cursor to the required object so that the cursor “trap” will capture the object.
2. Click the left mouse button. The object color will change— it will be highlighted with the color set for the selected objects (see Section 9.1.7.11 on p. 1713).

To de-select an object, click the left mouse button anywhere outside that object or press the *<Esc>* key. The selection will be removed — the object will revert to its original color.

If you need to select several objects, press the key *<Shift>* or *<Ctrl>* and, while holding it down, click the left mouse button on the desired objects. After completing your selection, release the *Shift* key (*Ctrl*).

You can select several objects using another method — by the **surrounding** or **cutting** marquee. Set the cursor at a free space (so that it does not reach to any objects), press the left mouse button and drag the cursor while holding the mouse down. The marquee will be rubber banding on the screen following the cursor.

- ▼ The surrounding marquee is formed when you move the cursor from left to right. It is displayed as a solid line. After you release the mouse button, those objects will be selected that are entirely inside the marquee frame.
- ▼ The cutting marquee is formed when you move the cursor from right to left. It is displayed as a dotted line. After you release the mouse button, those objects will be selected that are entirely or partially inside the marquee frame (the latter means those were intersected by the frame).

To deselect individual objects, click them with the left mouse button, while holding down the *<Shift>* or *<Ctrl>* key. You can deselect multiple objects by a rectangular marquee frame. This is done similarly to selecting, but with the *Shift* key pressed.

When deselecting by a marquee frame, watch that only selected objects are within the frame. Otherwise, the selection is not cleared; rather, it is applied to the previously not selected objects.

Sometimes, the objects that need to be selected are positioned closely to each other or even overlapping each other. At the same time, it is difficult (or sometimes utterly impossible) to precisely select one of them by the cursor.

The command **Object Picking Over** is used for selecting any of the nearby objects (including superimposed objects) (see Section 3.1.3.4 on p. 881).

3.1.3.2. Selecting Objects by Commands

The graphic objects selection commands are grouped together in the **Select** menu, and the commands for removing the selection — in the **Select — Exclude** menu.

The buttons for executing the commands are located on the **Selection** bar (Fig.3.1.12).

Fig. 3.1.12. **Selection** bar

The general selection commands are described in Table 3.1.4; for special selection commands see the following sections:

Select — Group — Section 3.9.2.4 on p. 1281,

Select — Layer — Section 3.5.6.7 on p. 1192,

Select — View — Section 3.5.5.4 on p. 1173,

Select — By Line Style — Section 3.2.1.1.1 on p. 894,

Select — By Attribute — Section 12.3.3.5 on p. 2069,

The objects, from which you want to remove the selection, are specified in the same way you specify objects for selection. The selection removal commands are available when the document has selected objects.

Tab. 3.1.4. General commands for selecting graphic objects

Command	Description
 Select All	Selects all objects contained in the current drawing view (about changing the view state see Section 3.5.5.2 on p. 1171) or in a fragment.
 Select Object	<p>Selects a separate object.</p> <p>After executing the command, point the cursor at the object you want to select.</p> <p>You can pick an arbitrary number of objects to select in a single command call.</p>

Tab. 3.1.4. General commands for selecting graphic objects

Command	Description
	<p>Select by Marquee It serves to select objects of the active document using a rectangular marquee frame.</p> <p>After executing the command, point the cursor at the first and second vertex of the rectangular marquee frame. The elements that are entirely within the set frame will be selected.</p> <p>You can define an arbitrary number of marquee frames in a single command call.</p>
	<p>Select Outside Marquee Serves to select objects of the active document that are outside the specified rectangular marquee frame.</p> <p>After executing the command, point the cursor at the first and second vertex of the rectangular marquee frame. The elements that are entirely outside the set frame will be selected.</p> <p>You can define an arbitrary number of marquee frames in a single command call.</p>
	<p>Select by Cutting Marquee Serves to select objects of the active document that are fully or partially within the specified rectangular marquee frame.</p> <p>After executing the command, point the cursor at the first and second vertex of the rectangular marquee frame. The elements that enter fully or partially into the set frame will be selected.</p> <p>You can define an arbitrary number of cutting marquee frames in a single command call.</p>
	<p>Select by Cutting Polyline Serves to select objects of the active document by crossing them with a polyline.</p> <p>After executing the command, point the cursor at the vertexes of the polyline. The objects intersecting with polyline segments will be selected.</p>
	<p>Select Previous List Serves to select objects that were selected on the previous occasion (elements of the previous list).</p>
	<p>Select by Type Serves to select all objects in the active document according to their type.</p> <p>After executing this command, you will see a dialog where you will have to specify the object types to be selected.</p>
	<p>Select by Properties Selects geometric objects of the active document according to a set of properties, excludes objects from selected objects according to a set of properties, and inverts selection. The Select by Properties command is examined in detail in Section 3.1.3.3.</p>

3.1.3.3. Select Objects by Properties

The **Select by Properties** command allows performing selection operations with objects (geometric, dimensions, designations) matching the specified conditions.

The following selection operations are available:

- ▼ adding objects to a group of selected objects,
- ▼ removing the selection of an object group,
- ▼ inverting the selection of an object group.

Inversion should be understood as selecting all objects in the document (or removing the selection of all objects in the document) with the exception of objects meeting the specified conditions.

The condition for including an object in a group is the correspondence of its properties to specified values. The properties, according to which objects are selected, are parameters that are specified on the Properties bar when creating a specific object. Belonging to types and layers is a common property of all objects.

To call the command, click the button **Select by Properties** on the **Selection** toolbar or select its name in the **Select** menu.

The dialog of object selection by properties will appear (Fig. 3.1.13). The control elements of this dialog allow selecting object types and conditions for performing selection operations on them.

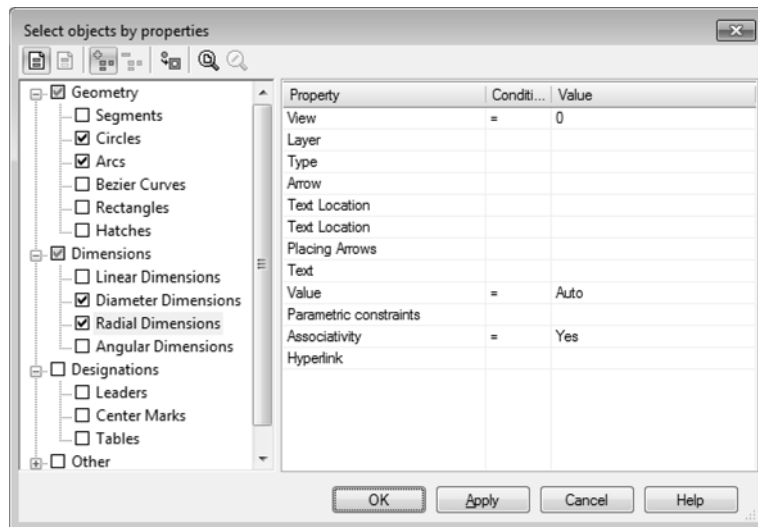

Fig. 3.1.13. Dialog of object selection by properties

The dialog toolbar buttons allow controlling the result of the object selection operations and changing the document view scale.

The object tree contains names of object types present in the current document. This set is formed automatically. The option next to the name allows controlling the inclusion of objects of this type in the group of objects being selected.

The table of selection conditions contains a list of properties of the object selected in the tree and allows specifying the conditions for including the object in the selection group, i.e., forming a selection filter.

To create a filter for selecting objects of a specific type, perform the following actions.

1. In the object tree, enable the option corresponding to the object type.
2. Select the property in the table.
3. In the **Condition** dropdown list, select the required option (Fig. 3.1.14). The set of available conditions depends on the property type.
4. Specify the condition value in the **Value** field. The method of specifying the value also depends on the property type. The values of numerical properties, such as *Length*, *Angle*, or the defining point coordinates must be entered from the keyboard. The values of other properties, such as *View*, *Style*, *Placing Arrows*, are selected from the dropdown list.

Fig. 3.1.14. List of conditions

To quickly specify properties common for all objects in the group, enable a root section option, such as **Geometry**. Select the common conditions and parameter values. In the object tree, disable the options of the object types to be excluded from the group. Proceed to specify the remaining parameters for each object type in the group.

Bear in mind the following specifics when specifying conditions.

- ▼ If the **View** has been selected in the *Property* column and its number has been specified in the **Value** column, when you select a layer the drop-down list will include only layers that belong to this view. If no view has been selected, all layers will be available for selection.
- ▼ If no property value has been specified in the table, the group will include all objects of a given type.
- ▼ If the property values have been specified but the object type option has been disabled, the objects will not be included in the group.
- ▼ If an option in the **Condition** column has not been selected, but the value has been specified, the option = will be used as the condition.
- ▼ If an option in the **Condition** column has been selected, but the value has not been specified, the properties are considered not to have been specified, meaning that the group will include all objects of the given type.
- ▼ If no condition has been specified for a property, no restrictions on selection operations with this object will be applied according to this condition.
- ▼ The group of objects for selection operations includes only those objects of the selected type which satisfy all of the specified conditions.

The buttons **Apply to All Objects** and **Apply to Selected Objects** allow specifying the application range of the filter — all objects in the document or only selected objects. The **Apply to Selected Objects** button is available if the document contains selected objects; it is pressed automatically if the document contained selected objects at the moment the dialog was opened. When this button is pressed, the object tree contains only those object types which are present among the selected objects.

The button **Add to Group** allows adding to the selection group those objects that satisfy the specified conditions.

The button **Exclude from Group** allows excluding from the selection group the previously selected objects that satisfy the specified conditions. The button is available if the document contains selected objects.

The button **Invert Selection** allows inverting the selection state of the objects in the document.

The result of the inversion depends on the status of the **Add to Group** and **Exclude from Group** buttons. If any objects are selected in the object selection tree when the **Add to Group** button is depressed, these objects will be added to the selected objects and the result inverted. When the **Exclude from Group** button is depressed, the selection will be removed from these objects and the result inverted.

After executing the command a single time, you can perform several actions of adding and excluding documents of several types as well as inverting the selection. To perform the action without exiting the dialog, use the **Apply** button.

You can change the document image scale in the following ways without interrupting the command.

The button **Show All** will change the display scale in the active window in such a way as to fully show the entire document.

The button **Selected Objects Scale** serves to automatically change the display scale in the active window in a way as to have all selected objects fit in the largest possible scale. The command is not available if no object is selected.

Selected construction lines and empty (containing no objects) views are ignored when performing the command. A single selected point is also disregarded.

To complete the selection operations, click the **OK** button in the dialog.

After selecting several objects with the selection command, you can execute a different selection command and continue selecting objects — the selection of the previously selected objects will not be removed.

3.1.3.4. Object Picking Over

Sometimes an object you need to specify is located near other objects or overlaps other objects. At the same time, it is difficult (or sometimes utterly impossible) to select it with the cursor.

To select any of the nearby-located objects (including the overlapping ones), use the object pick-over mode. Picking over is possible when the system waits for an object to be **selected** or **specified**, and at the same time several objects fall in the cursor's catcher.

You often need to **select objects** before running a command. For example, to get a copy of an object, you have to select the source object.

Objects must be selected in order to perform certain commands. For example, to construct a parallel line segment you have to specify an object to which the line segment being created should be made parallel.

Picking Over when Selecting Graphical Objects

1. Point the cursor to the group of objects containing the desired one, and select any of them.
2. Call the context menu command **Object Picking Over** or press the `<Ctrl>+<t>` keys.
3. Pick over objects by pressing the `<Space>` key or calling the **Next Object** command from the context menu. Objects grabbed by the cursor catcher at the time of selecting the first object will be highlighted one after another.
4. 4. When the desired object is highlighted, call the **Finish Object Picking Over** command. You can also press the `<Enter>` or left-click the selected object. Picking over will end at the current object.

You do not need to end the picking over. You do not need to end the picking over. You can call the command that requires an object selection right after the latter highlights.

Picking Over Graphic Objects

1. Point the cursor to the group of objects containing the desired object.
2. Without selecting any of them, call the context menu command **Object Picking Over**. You can also press the `<Ctrl>+<t>` keys.
3. Pick over objects by pressing the `<Space>` key or calling the **Next Object** command from the context menu. Objects pointed at by the cursor at the time of calling the picking over command will be highlighted one after another.
4. When the desired object highlights, finish the pick-over mode by confirming the selection. To do this, call the **Select highlighted object** command from the context menu or press the `<Enter>` key. You can also click the mouse on the highlighted object or at any free space of the document window.
5. To exit the picking over mode without selecting any object, call the context menu command **Cancel Picking Over**. You can also press the `<Esc>` key.

The system will return to the mode of executing the command for which the object was selected.

3.1.3.5. Using the Clipboard

When working with drawings, it may become necessary to copy or move some portion of the image within one document or to other documents.

For these purposes, KOMPAS-3D uses its own clipboard, not the standard Windows clipboard.

Sometimes (usually when moving text fragments) the Windows clipboard can be used. It is indicated in the descriptions of the relevant operations.

The amount of information that can be put in the clipboard is unlimited. The clipboard content is saved on disk in a special system file. When copying or cutting to the clipboard again, its previous contents are deleted.

The clipboard helps quickly and conveniently copy or move drawing objects. However, when you need to perform a precise move or complex copying (e.g. on a rectangular or concentric grid), use special edit commands (see Section 3.4.2 on p. 1120 and Section 3.4.3 on p. 1122).

Information can be copied and moved via the clipboard only between documents opened in the same KOMPAS-3D application.

3.1.3.5.1. Placing Objects into Clipboard

Objects can be placed into the clipboard with or without it being cut out from the document.

In the first case, the objects are **cut to the clipboard**. The process that involves cutting to the clipboard and pasting from the clipboard is called **moving via clipboard**.

In the second case, the objects are **copied to the clipboard**. The process that involves copying to the clipboard and pasting from the clipboard is called **copying via the clipboard**.

When copying or cutting to the clipboard again, its previous contents are lost.

To place objects into the clipboard, perform the following actions.

1. Select all objects (for selecting methods see Section 3.1.3 on p. 876) you want to place into the clipboard.

2. Call The **Edit — Cut command** (to cut to the clipboard) or **Edit — Copy** (to copy to the clipboard).

The cursor appearance will change.

3. Select a point that will serve as the base for the selected set of objects.

You do not have to specify a base point, if you have selected:

- ▼ objects belonging to different drawing views,
- ▼ several views in their entirety.

In this case, the origin of the absolute coordinate system is automatically adopted as the base point (the bottom left corner of the drawing sheet).

Also, you do not have to specify a base point if you are placing a text fragment into the clipboard.

3.1.3.5.2. Insert from the Clipboard

To paste objects contained in the clipboard into the active document, call the command **Edit — Paste**.

If the clipboard contains objects belonging to different views of a drawing and/or entire views, they will be immediately pasted into the drawing. The inserted documents are placed in the views with the same parameters as the source objects.

Since a fragment cannot contain views, you cannot paste views or objects belonging to different views into a fragment.

If the clipboard contains objects belonging to a fragment or one kind of drawing view, the ghost of the objects being pasted will be shown on the screen and on the Properties bar — paste control elements. These elements are presented in Table 3.1.5.

Tab. 3.1.5. Clipboard paste control elements

Element	Description
Base point	Coordinates of the base point of the objects being pasted.
Angle of Rotation	Object rotation angle around the base point.
Scale	Object scale factor.
Mode	A group of switches controlling the placement of the objects in multi-layer pasting. Available if the clipboard contains objects belonging to different layers (for layers see Section 3.5.6 on p. 1181). The activation of the To Current Layer switch means the whole image will be placed on one (current) layer of the active document. The activation of the To Source Layers switch means that the missing layers for the object placement will be created in the active document.
Extension Lines	Group of switches controlling the scale of the extension lines and the dimension leaders (see Section 3.4.4.2.1 on p. 1131) *.

* When you copy via the clipboard an object that is a fragment insertion (see Chapter 3.7.2 on p. 1248), the leaders and the extension lines are scaled if the option **Scale Extension Lines** was enabled when pasting this fragment, and not scaled if this option was not enabled, meaning that in this case the status of the **Scaling of Extension Lines** button does not matter.

Once the anchor point is fixed, the clipboard contents are pasted into the document.

You can keep inserting objects, placing them in the appropriate positions within the document, and setting the desired scale and rotation angle. An unlimited number of insertions can be made from the clipboard within one command call.

3.1.4. Grid. Orthogonal drawing

3.1.4.1. Using the Grid

When you work with a graphic document or an operation sketch, it is often very convenient to enable the grid on the screen and establish a link to its nodes. In this case, the cursor will not move smoothly, but discretely through the grid nodes. This working mode can be compared with drawing an image on a square-ruled plotting paper.

The grid is not a part of the document and is not printed to paper.

The grid may appear differently in different windows, even in windows of one and the same document. It is possible to set different grid steps by the respective axes, to draw a grid with nodes, or to assign a grid that is reversed with respect to the current coordinate system or a non-rectangular (skewed) grid.

Management of the grid display in the current window is performed by means of the **Grid** button on the **Current Status** bar.

This button also indicates whether the grid is present in the window: a depressed button means that the grid is enabled, while a released button means it is disabled.

The grid is controlled by means of a special menu that opens when you click the arrow button next to the **Grid** button.

The commands of this menu are described in Table 3.1.6.

Tab. 3.1.6. Grid control commands

Command	Description
Customize parameters	Allows configuring the grid settings in the active window. After you execute the command, the grid setup dialog appears (see Section 9.1.7.2 on p. 1705).
Show parameters	Controls the display of the basic grid parameters — distances between its visible nodes* along the axes X and Y of the current coordinate system — on the Current Status bar (Fig. 3.1.15)**. After you execute the command, the grid parameters will be displayed regardless of whether the grid view is enabled or disabled.
Show Settings if Grid Is On	Controls the display of the basic grid parameters on the Current Status** bar. After you execute the command, the grid parameters will be displayed on the bar only if the grid is enabled.

* When the image is zoomed out, not all grid points are visible on the screen (the grid will be resampled down), which is why the distance between the nearby visible points differs from the distance between the points specified in the grid setup dialog.

If the grid is disabled, the grid parameters under any scale match the grid steps along the axes X and Y specified during setup (see Section 9.1.7.2 on p. 1705).

** The grid parameters are displayed on the bar when it is located horizontally.

Fig. 3.1.15. Displaying grid parameters on the **Current Status** bar

3.1.4.2. Snapping by Grid

The fact that the grid is present on the screen does not mean that the cursor is attached to its points. The activation of the desired snapping option is done separately (see Fig.3.1.3 on p. 868).

The opposite is also true: The opposite is also true: the grid view in the window can be disabled, but this does not prevent the attachment to the grid.

The global snapping to the grid (as any other global snapping) works only in the window in which it was set.

If no constant attachment to the grid is needed, disable the global attachment to the grid.

In this case, you can attach the cursor to a grid node by enabling a local snap (see Section 3.1.1.2.2 on p. 868).

3.1.4.3. Grid View in Zoomed Out Windows

If the grid view in the window is enabled, each time you change the view scale (see Section 1.4.1.2 on p. 76), the system will take into account this change when redisplaying the grid. When the view is zoomed out to a point where the grid with the specified spacing cannot be displayed correctly because of its density, a **resampled down** grid will be displayed.

The grid density limit is determined by the value specified as the **Minimum Grid Spacing** (see Section 9.1.7.2 on p. 1705). As long as the number of pixels between the points exceeds the minimum grid spacing value, the grid is not resampled down. The grid is resampled down when the view is zoomed out beyond this point.

The resampling of the grid is performed taking into account the resampling down step specified during setup.

If the grid spacing divisibility is set to **From Sequence** (see *ibid.*), the grid spacing will be divisible by numbers from the sequence of 2, 5, 10, 20, 50, 100, 200, 500, 1000, 2000, 5000, 10000, 20000, 50000, 100000, 500000. This means that when you set the display scale not allowing to that does not permit correctly displaying every point, there will be displayed every second grid point will be displayed; with further scaling down— every fifth, then tenth, etc.

If the **Ratio** resampling down step has been set (see *ibid.*), the grid spacing will be always divisible by the specified number. For example, setting the resampling-down step a multiple of 2 means that upon decreasing the image scale, first every second of the grid nodes will be shown, then every fourth one, then every sixth, and so on.

3.1.4.4. Orthogonal Drawing

The orthogonal drawing mode is intended for quick creation of objects or their portions that are orthogonal to the axes of the current coordinate system.

Enabling and disabling of this mode can be achieved by clicking the **Orthogonal Drawing** button on the **Current Status** bar. Another way to control the orthogonal mode is to press the *<F8>* key.

This key also serves as an indicator of the orthogonal drawing mode: the pressed button means that the Orthogonal Drawing is enabled, the released button means it is disabled.

If in the process of inputting an object you need to temporarily disable (or enable) this mode, press and hold the *<Shift>* key.

The orthogonal mode is used for drawing horizontal and vertical lines, designations of stepped cuts, mutually perpendicular portions of geometric tolerance branches, and in other cases — form tolerance.

To get familiar with working in the orthogonal drawing mode, complete the following steps.

1. Create a new graphic document (drawing or fragment). Make sure that the orthogonal drawing mode is disabled. Enable it, if necessary.
2. Call the **Tools — Geometry — Lines — Line** and specify the start point of the line with the cursor.
3. Move the cursor around the document field and watch the line segment ghost.
The end point of the line segment coincides with the cursor; it can be fixed at any position on the drawing by clicking the left mouse button.
4. Enable the orthogonal drawing mode.
5. Move the cursor.
Now the line ghost is strictly horizontal or vertical depending on the direction to which the cursor is closer.
6. Set the end point of the segment.
7. Enter the start point of the other line.
8. Move the pointer across the document area. Make sure the line ghost is being constructed orthogonally to the axes of the current coordinate system.
9. Press and hold the *<Shift>* key and continue moving the cursor.
Make sure that the orthogonal mode has switched off, and the segment is being created in the normal mode, following the cursor motion.
10. Release the *<Shift>* button. Make sure that the system is back in orthogonal mode.
11. Create a local coordinate system (see Section 3.1.5.2.1 on p. 888).
12. Create several line segments, selecting their start and end points by the cursor. Make sure that the line segments are created orthogonal to the current LCS axes.

3.1.5. Coordinate Systems in a Graphic Document

3.1.5.1. Absolute coordinate system

Each drawing has an **absolute coordinate system**. Its origin is always in the bottom left corner of the external border. The notion of absolute coordinate system has no meaning for the

fragment (there are no apparent bounds, as in the case of a drawing); therefore, when creating a new fragment, the coordinate system origin is displayed in the center of the window.

3.1.5.2. Local coordinate systems

Using the absolute coordinate system alone is not always convenient. When designing, one often needs to measure distances or corners not from the bottom left corner of the sheet but from a different point.

KOMPAS-3D uses local coordinate systems (LCS) to enable this method of specifying object properties. By setting the LCS at certain points of a part or node being designed, you can quickly select any of them and it current. In this case, all coordinates will be calculated and displayed relative to this coordinate system. When an LCS is no longer needed, you can quickly delete it from the document.

3.1.5.2.1. Creating a Local Coordinate System

To create a local coordinate system in the document, call the command **Insert — Local CS** or press the **Local CS** button on the **Current Status** toolbar.

The LCS control elements will appear on the Properties bar. These elements are presented in Table 3.1.7.

Tab. 3.1.7. The LCS control elements on the Properties bar

Element	Description
Select LCS	A bar containing the list of LCSs in the current document.
Name of the Local CS	Name of the LCS selected in the list. You can enter any name for any LCS in this field.
Origin of the Local CS	Coordinate fields of the origin of the selected LCS. The point coordinates are set up in the current coordinate system.
Slope of the Local CS X Axis	X axis rotation angle field of the selected LCS. This angle is calculated from the X axis of the current coordinate system.
Settings...	Button that lets you configure the way the LCS is displayed. After you click this button, the LCS setup dialog appears (see Section 9.1.7.10 on p. 1712).

3.1.5.2.2. Managing Local Coordinate System

To configure LCSs in the document, make some of them current or remove, call the **Insert — Local CS** command or click the **Local CS** button on the **Current Status** bar.

The elements shown in Table 3.1.7 will appear on the Property bar.

- ▼ To set any LCS as the current coordinate system, select it in the list (when you do so, it will be displayed on the screen) and click the **Current Local CS** button in the **Select LCS** window. A checkmark will appear next to the current LCS in the list.

If none of the LCS is selected as the current one, the absolute coordinate system will be considered the current one.

- ▼ To remove the selected LCS, click the **Delete Local CS** button.
- ▼ In order to create a new LCS, click the **New Local CS** button.

Moreover, selecting any LCS in the list, you can enter a new name, coordinates of the origin, and rotation angle.

You can cancel any of the actions mentioned above by clicking the **Undo** button on the **Standard** bar.

3.1.6. Controlling the Order of Displaying Objects

When displaying and printing graphics documents, the order of drawing objects is taken into account. The default order of drawing is determined by the system automatically depending on the object type: first drawn are hatches and fills, on top of them — auxiliary (construction) lines, then line segments, circles, ellipses, etc. As a result, the objects overlap each other in the order they were drawn.

The overlapping effect is particularly noticeable when working with multicolor fields and hatches as well as with colored lines of enhanced weight.

For example, suppose there are a rectangle, a hatch and a linear dimension in a document. By default, they are ordered as follows: hatch, rectangle, dimension, i.e., the hatch is overlaid by the rectangle and the dimension, while the rectangle is overlaid only by the dimension.

At any time while working with the document, you can modify the default order of the objects with respect to each other. To do this, select the object, whose order needs to be modified, and call the appropriate command from the menu **Edit — Order**. These commands are described in Table 3.1.8.

Tab. 3.1.8. Commands for controlling object visibility

Command	Description
 To Front	Sends the highlighted object on top of the rest. As a result, the relocated object will be on the top, overlapping all the rest.
 To Back	Sends the highlighted object behind the rest of the objects. As a result, the relocated object will be overlapped by all the rest.
 Before Item	Sends the highlighted object before the current one. After calling the command, you need to pick by the cursor the object before which the selected one should be placed. As a result, it will overlap the selected object and all previous objects.

Tab. 3.1.8. Commands for controlling object visibility

	Command	Description
	Behind Object	Sends the highlighted object behind the current one. After calling the command, you need to select the object behind which the selected one should be placed. As a result, it will be overlapped by the selected object and all objects to follow.
	One forward	Swaps the selected object and the object before it.
	Back One	Swaps the selected object and the object behind it.

The visibility control commands are also available in the context menu of the selected object.

The visibility modifying commands can be applied to several selected objects at the same time. In this case, the neighboring objects (those located on the neighboring levels) are moved as a single object.

When you attempt to select with the mouse (see Section 3.1.3.1 on p. 876) one of the overlapping objects, the one in the front will be highlighted. To select objects located under this object, use the pick over command (see Section 3.1.3.4 on p. 881).

When setting up the visibility of the objects in graphic documents, keep in mind of the following special considerations.

- ▼ The visibility can be changed for objects belonging to the current and active layers of a fragment (for details on layers, see Section 3.5.6 on p. 1181) or to the current view of a drawing (for details on views, see Section 3.5.4 on p. 1160).
- ▼ The visibility of the objects belonging to different views is determined by the system automatically: the views that were created more recently are considered in position in front of the views that were created earlier. Therefore, for example, the objects of the very first — the system — drawing view are overlapped by the objects of all the rest of the views. You cannot modify the relative order of the views.
- ▼ The following objects are always in front of all the rest in the drawing objects:
 - ▼ outer and inner frames,
 - ▼ title block,
 - ▼ Specifications,
 - ▼ unspecified surface finish,
 - ▼ BOM in Drawing.
- ▼ Objects forming an embedded fragment (see Section 3.7.2.1 on p. 1248) are arranged relative to one another just as they are arranged in the source fragment. A fragment insertion occupies **one level** of visibility in the main document. Therefore, when working with the main document,

you cannot change the order of the objects that make up the insert. To do this, you need to edit the inserted fragment itself.

- ▼ A macroelement (see Section 3.7.5 on p. 1254), just like a fragment insertion, occupies one visibility level. Immediately after its creation, the macroelement is positioned in front of all the other objects. The objects within the macroelement are positioned with respect to each other in the same way as before the grouping.

3.1.7. Creation of object by sample

One of the methods of creating a new graphical object is creating an object with the properties of an existing one (sample). In order to create an object similar to an existing one, use the **Object by sample** command.

When performing the **Object by sample** command, properties of the sample object are copied to the new object. Samples may be geometrical objects (except for contours and elliptical arcs), symbols, and dimensions. The set of copied properties depends on the sample object type.

Example. There is a fill inside a circle in a document. The **Object by sample** command makes it possible to create another fill with the same properties (type, color, transparency, and so on) inside a different contour.

In order to create an object by sample:

1. Click the **Object by sample** button on the **Geometry** toolbar (see Fig. 3.2.1) or select its name in the **Instruments** menu.

The cursor will change its appearance.

2. Specify the object that will be used as a sample for copying properties. For this purpose, place the cursor on the object. When the selected object highlights, click the left mouse button.

Once the object is specified, the command, corresponding to the specified object's type, will be run. For example, if the sample object is a segment, the **Segment** command will be run.

3. Specify the parameters of the new object. For example, segment requires vertices to be specified. Style of the segment's line will be the same as the style of the sample segment.
4. Finish creating the object.

The **Object by sample** command can be interrupted prior to running the command, corresponding to the specified object's type. You can do it using one of the following methods:

- ▼ Click the **Interrupt command** button on the Special Control Panel,
- ▼ Call the **Interrupt command** command from the context menu,
- ▼ Press the <Esc> key.

If the sample objects has already been highlighted prior to calling the **Object by sample** command, the command corresponding to the sample object type will be run immediately after calling the command.

3.2. Geometrical Objects

3.2.1. General Information on Geometric Objects

It is possible to create geometrical objects of the following types in KOMPAS-3D system:

- ▼ points,
- ▼ lines,
- ▼ line segments,
- ▼ circles,
- ▼ ellipses,
- ▼ circle arcs and ellipses,
- ▼ rectangles,
- ▼ regular polygons,
- ▼ polylines,
- ▼ splines (NURBS, Bezier curves),
- ▼ multilines,
- ▼ hatches and fills,
- ▼ offset curves,
- ▼ contours.

Commands for creating these objects are grouped under the **Tools — Geometry** menu, and buttons for executing the commands — on the **Geometry** bar (Fig. 3.2.1).

Fig. 3.2.1. **Geometry** bar

If any actions are performed identically for similar commands, such actions will be described only once when you first come across them in this text.

3.2.1.1. Geometric Object Styles

The appearance of a geometric object is determined by its **style**.

KOMPAS-3D comes with system styles for points, lines, and hatches. System styles of lines and hatches correspond to standard styles. You can create custom styles for lines and hatches.

The *Auxiliary* style is one of the system styles for points and lines. It is intended for objects that perform auxiliary functions— points and lines created during layout operations, preliminary design, etc. Once these objects are no longer necessary, they are deleted.

If auxiliary objects have the same style, you can quickly delete all of them by clicking **Edit—Delete— Construction Curves and Points** (see Section 3.4.8.1 on p. 1144). This is why we recommend using a corresponding style when building an auxiliary object. If the object you are

creating is not going to be deleted together with auxiliary objects, you should select a different style for this object.

When you are creating a geometric object, the current style is shown in the same-titled field on the Property bar. To change the style, open the **Style** list and select the required style name (Fig.3.2.2).

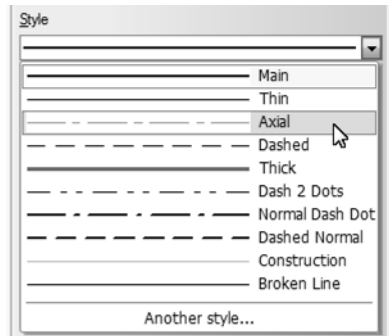

Fig. 3.2.2. Selecting the line style

The list and sequence of line styles in the **Style** list as well as the default style are determined by the line style list setting (see Fig.9.2.6.6 on p. 1763).

When you create lines (see Section 3.2.3 on p. 901), they are automatically assigned the *Auxiliary* style. It is impossible to choose a different style.

The appearance of points and lines with system styles depends on the system settings. If necessary, you can modify it (see Sections 9.1.7.4 on p. 1707 and 9.1.7.5 on p. 1708).

3.2.1.1.1. Selecting Curves by Style

To select all same-style lines in the document, perform the following steps.

1. Call the **Select — By Line Style...** command. A dialog listing all line styles used in the document will appear.
2. Select the required style(s) in the dialog.
Objects having the specified style(s) will be selected.

3.2.1.1.2. Changing the Object Style

To change the style of an existing geometric object(s), perform the following steps.

1. Select the object(s) whose styles you want to change (for selection methods see Section 3.1.3 on p. 876).
2. Call the **Service— Change Style** command. A style modification dialog will appear (Fig.3.2.3). The number of dialog tabs depends on the type of selected objects (lines, points, hatches, text).
3. Specify the settings and confirm style change.
See section 3.6.2.7.1 on p. 1220 for more information about changing the style of hatches in associative views of a drawing.

Fig. 3.2.3. Style change dialog

3.2.1.2. List of line styles

Every graphic document stores a **list of line styles**: the information on what styles can be used in this document.

By default, the list contains system line styles only. If necessary, the user can add styles to the list from style libraries or sets.

You can apply the **style filter** to the line style list to limit the set of styles displayed in the **Style** list on the Property Bar (see Fig.3.2.2) when creating geometric objects. It is recommended to show several most used styles only. When needed, you can choose any other style **or create a new one** to draw an object using the **Another Style...** row in the Style list. Line style filter settings are described in Section 9.2.6.6.1 on p. 1763.

3.2.1.2.1. Line Style Manager

The Line Style Manager (Fig.3.2.4) serves to manage a line style list of the current or new documents.

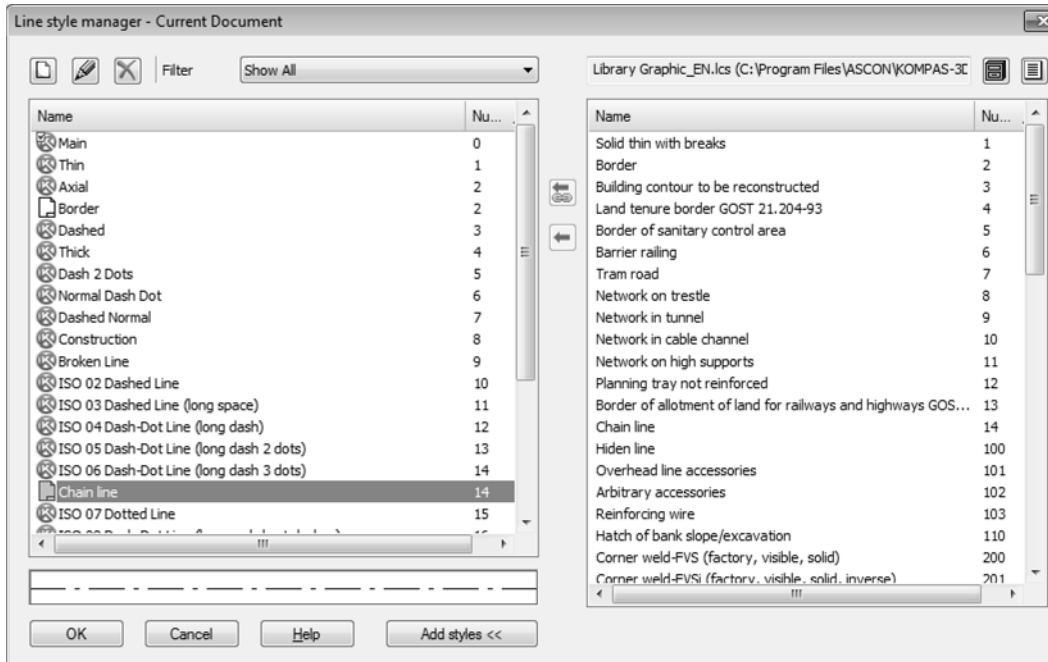

Fig. 3.2.4. Line Style Manager during the line style list setting up for the current document

By default, the Line Style Manager is opened in minimized view, i.e.

only its left part is displayed. It contains the list of line styles: The styles are marked with the following signs:

- ▼ **System** style,
- ▼ **Embedded** in a document style,
- ▼ **Library** style.

In the line style list of the current document the marks can be accompanied by a “check” showing that the style is involved in the document, i.e. is **used**. For instance, Figure 3.2.4 shows the *Main* and *Auxiliary* styles that are used.

The right part of the Line Style Manager appears after clicking the **Add Styles** button. This part serves for selection of a library (set) of styles and embedding of styles from it to the list of document styles.

The Line Style Manager controls are described in Table 3.2.1.

Tab. 3.2.1. Line Style Manager Controls

Element	Description
 New	The button allowing creation of a style. A new style is added to the document style list as an embedded one. The curve style creating or editing dialog is displayed after this button is clicked.

Tab. 3.2.1. Line Style Manager Controls

	Element	Description
	Edit	<p>The button making it possible to edit a selected style. It is available when an embedded style is selected in the document style list.</p> <p>The curve style creating or editing dialog is displayed after this button is clicked.</p>
	Delete	<p>The button allowing to delete selected styles. It is available if unused styles (embedded and/or library ones) are selected in the document style list.</p> <p>After clicking this button, the dialog that allows to confirm or revoke the deletion.</p>
	Filter	<p>List of filters for the list of document styles:</p> <ul style="list-style-type: none"> ▼ Show All, ▼ System Styles, ▼ Embedded Styles, ▼ Library Styles, ▼ Used Styles, ▼ Unused Styles. <p>To apply a filter, select it from the Filter list. Only those styles, which correspond to the applied filter, will remain in the list.</p>
	Add styles	<p>This button allows to add styles from a library or set to the document style list. After clicking it an additional area with control elements will appear in the Line Style Manager.</p> <p>To close this area, the Add Styles button shall be clicked repeatedly.</p>
	Show Library	<p>The button serves for line style library selection. After its clicking, the dialog where it is required to indicate the line style library file (*.lcs) and click the Open button, appears on the screen.</p> <p>The list of library styles of lines appears in the preview window.</p>
	Show Set	<p>The button serves for line style set selection. After its clicking, the dialog where it is required to indicate the set name and click the Select button, appears on the screen.</p> <p>The list of line styles from a set appears in the preview window.</p>
	Add library style	<p>It allows to add one or several library styles to the document style list. It is available when there are selected styles in the list of library styles.</p> <p>After clicking this button, the selected styles will be included into the document style list as the library styles.</p> <p>Library styles maintain the link with library files, from which they were added to the document.</p>

Tab. 3.2.1. Line Style Manager Controls

Element	Description
	<p>Embed Style into Document</p> <p>It allows to embed one or several library styles or styles from a set to a document.</p> <p>It is available when there are selected styles in the list of library styles or styles form a set. After clicking this button, the selected styles will be included into the document style list as the embedded styles.</p> <p>Styles embedded to a document from libraries do not maintain the links with the files of these libraries.</p>

Library styles with broken connection

Document library styles lose connections with the library in the following cases:

- ▼ you move the library file from which the styles were added to the document to another folder;
- ▼ you delete respective styles from the library.

When you open the document which style list contains styles with broken connection, the message pops up saying that styles or style libraries are not found.

Library styles with broken connection have an exclamation mark within a red circle in the Line Style Manager.

Connections can be restored in one of the following ways:

- ▼ place the library file using the previous path and then close and open the document— the library and its styles will be found;
- ▼ without moving the library, open it in the Line Style Manager and add its styles to the document style list once more— the previous library file path will be replaced with the current one.

If there are several library styles with broken connection in the list, you can use the **Library, with Broken Connection** filter for convenience in operation.

If a library or its styles cannot be restored, edit the objects that use styles with broken connection by setting other styles for them and then delete the styles with broken connection from the document style list. For instance, you can do the following.

1. Open the Line Style Manager, remember the style name that lost connection with the library and close the Line Style Manager.
2. Select the document objects that use this style with the **Select— By Line Style...** command.
3. Replace the style of the selected objects with another one (see Section 3.2.1.1.2 on p. 894).
4. Open the Line Style Manager, delete the style that lost connection with the library and close the Line Style Manager.

The lines that use the style with broken connection retain their typeface, therefore you may leave their style unchanged (e.g. if there are no styles to be replaced). But you won't be able to delete the style with broken connection in this case; a warning will pop up when the document is opened.

3.2.2. Points

KOMPAS-3D offers a variety of ways to draw points as well as several point layout styles. This allows using points both as auxiliary elements and independent geometric objects.

3.2.2.1. Random Point

To draw a randomly located point, click **Point**.
Define the point position.

3.2.2.2. Points on Curve

To draw several points dividing a curve into several equal sections, click **Points on Curve**.
In the relevant field on the Property bar, enter the number of sections that you want the curve divided into.

Select a curve to set points.

If a curve is not closed, then the points will be created right after its selection. The first point will coincide with the start point of the curve, the last point—with the end point.

If a curve is closed, then, after selecting it, you need to define the position of the first point on it (define the point **p1**).

Fig. 3.2.5. Example of curves (closed and open) divided into equal sections

If the specified point does not belong to the selected curve, then the first point position will be determined by the projection (mapping) of the specified point on the curve. Use snaps for precise positioning of the cursor (see Section 3.1.1 on p. 865).

If you want to break a curve into several equal sections without drawing points, use the **Break Curve into N Parts** command (see Section 3.4.6.2 on p. 1136).

3.2.2.3. Intersection Points of Two Curves

To draw points at intersections of curves, click **Intersection Points of Two Curves**.

Select a curve to search for intersections. Then, sequentially select the curves that intersect it.

After selecting each subsequent curve, the points are automatically created in the locations of its intersection with the first curve.

Fig. 3.2.6. Example of drawing points at intersections of an ellipse and circle

To select another line to process for intersections, click the button the **Reselect** button and proceed to specify the required lines.

3.2.2.4. All Intersection Points of Curve

To draw points at all intersections of the selected curve with other lines, click **All Intersection Points of Curve**.

Select a curve to search for intersections.

Points will be created automatically at its intersections with other curves located in current and active views (for drawing views see Section 3.5.5.2 on p. 1171) and layers (for layer types see Section 3.5.6 on p. 1181).

Fig. 3.2.7. Example of setting all intersection points of an ellipse with two curves

You can draw all intersection points of an auxiliary line immediately after creating it using the **Mode** switch (see Section 3.2.3.1.1 on p. 901).

3.2.2.5. Point at Specified Distance

To draw points on a curve located at a specified distance from a selected point on this curve (reference point) and from each other, click **Point at Specified Distance**.

In the relevant field on the Property bar, enter the number of points you want to create.

Select a curve to set points.

The **Reselect** button allows selecting a different curve for drawing points.

Specify the base point on a curve— the **p** point.

If the specified point does not belong to the selected line, then the base point position will be determined by the projection (mapping) of the specified point on the line. Use snaps for precise positioning of the cursor (see Section 3.1.1 on p. 865).

In the **Distance** field of Properties bar, enter the distance between the reference point in the first point being created. If several points are being created, then the specified value will also define the distance between them.

As the cursor moves around the reference point, the ghosts are displayed for the point (points) that can be created. Fix the required ghost.

Fig. 3.2.8. Example of three points drawn along an arc at a distance of 5 mm from the reference point

3.2.3. Construction lines

Straight lines are the equivalent of thin lines used by the designer on the drawing board. They are required for preliminary construction that is subsequently used to draw the final contour of a part, and sometimes— to specify projection correlations between views.

Straight lines have the *Auxiliary* style that cannot be changed.

Auxiliary straight lines (as well as other lines with the *Auxiliary* line style) are not printed out to paper.

3.2.3.1. Arbitrary Straight Line

To draw an arbitrary straight line, click **Auxiliary Line**.

Specify the first point through which the straight line should pass— **p1**.

- ▼ If you know the location of the second point belonging to the straight line (**p2**), specify it. The line inclination angle (the angle between the line and the X-axis of the current coordinate system) will be determined automatically.

Fig. 3.2.9. Creating a line by two points

- ▼ If you know the tilt angle of the straight line you are creating, enter it into the relevant field on the Property bar.

3.2.3.1.1. Drawing Intersection Points

When building auxiliary elements, you sometimes need to draw points where lines intersect between each other and with other objects.

By default, these points are disabled, and the **Do not Set Intersection Points** switch is active in the **Mode** group. To enable the points, activate the **Set Intersection Points** switch.

If the mode of setting intersection points is enabled, then, when creating a new auxiliary line, the system will automatically put intersection points of that line with all graphical objects lying on the active layers of the current view (See Section 3.5.5.1 on p. 1171).

Fig. 3.2.10. Creating auxiliary lines a) with auxiliary points, b) without auxiliary points

Automatically drawn points have the *Auxiliary* style.

If necessary, you can delete them all by a single command together with other auxiliary (construction) elements (see Section 3.4.8.1 on p. 1144).

If you need to select not all intersection points on the line, but only its points of intersection with certain objects, use the **Intersection Points of Two Curves** command (see Section 3.2.2.3 on p. 899).

3.2.3.2. Horizontal Line

To create a horizontal straight line, click **Horizontal Line**.

Then define the point, through which the created line should go.

A line which is parallel to the X-axis of the current coordinate system is a horizontal line. Therefore, if you create a horizontal line on a view, whose coordinate system is rotated relative to the absolute coordinate system, then this line will not be parallel to horizontal borders of the sheet.

3.2.3.3. Vertical Straight Line

To create a vertical straight line, click **Vertical Line**.

Then define the point, through which the created line should go.

A line which is parallel to the Y-axis of the current coordinate system is a vertical line. Therefore, if you create a horizontal line on a view, whose coordinate system is rotated relative to the absolute coordinate system, then this line will not be parallel to vertical borders of the sheet.

3.2.3.4. Parallel Line

To draw a line parallel to a rectilinear object, click **Parallel Line**.

Rectilinear objects include:

- ▼ construction lines,
- ▼ line segments (also as a part of polylines, polygons, contours),
- ▼ dimension lines and dimension leaders,
- ▼ table lines.

Specify a straight object relative to which you want to draw a parallel line.

Specify the distance from the straight object to the parallel line. You can do this by the following methods:

- ▼ enter the distance value into the relevant field on the Property bar,
- ▼ then define the point, through which the created line should go.

By default, the system shows the ghosts of two lines positioned at the specified distance on either side of the straight object. In this case, the **Two Straight Lines** switch is active in the **Number of Straight Lines** group.

To enable the creation of a single line parallel to the object, activate the **One Straight Line** switch.

Fix the ghost of a line (or two lines).

Fig. 3.2.11. Lines parallel to a line segment

To proceed to building lines parallel to a different object, click the **Reselect** button and proceed to select the required straight object with the pointer.

3.2.3.5. Perpendicular Straight Line

To build a straight line perpendicular to another object, click **Perpendicular Line**.

Select the object, which the straight line should be tangent to. Proceed to specify a point on the straight line.

The ghosts will be displayed for all possibilities of straight lines perpendicular to the selected object and going through the specified point.

Activate a suitable ghost and fix it.

Fig. 3.2.12. Lines perpendicular to the spline

To proceed to building lines perpendicular to a different object, click the **Reselect** button and select the required object.

3.2.3.6. Straight Line Tangent to Outside Point

To draw a line tangent to an object and passing through a point specified outside of this object, click **Straight Line Tangent to Outside Point**.

Select the object to which the straight line should be tangent. Proceed to specify a point on the straight line.

The ghosts of all possible lines tangent to the object and passing through the specified point will be displayed.

Activate a suitable ghost and fix it.

Fig. 3.2.13. Straight lines tangent to ellipse

To proceed to building lines tangent to a different object, click the **Reselect** button and proceed to select a different object.

3.2.3.7. Straight Line Tangent to Point on Curve

To draw a line tangent to an object at point on the object, click **Straight Line Tangent to Point on Curve**.

Select the object to which the straight line should be tangent. The arc ghost will be displayed.

- ▼ If you know the tangent point location, specify it.

If the specified point does not belong to the selected line, then the dividing point position will be determined by the projection of the specified point on the line. Use snaps for precise positioning of the cursor (see Section 3.1.1 on p. 865).

- ▼ If you know the inclination angle of the tangent line (the angle between the line and the X-axis of the coordinate system), enter it in the **Angle** field on the Property bar.
Fix the ghost(s).

Fig. 3.2.14. Line tangent to the spline: a) passing through a spline point, b) having a specified tilt angle

To proceed to creating straight lines tangent to another object, click the **Reselect** button and proceed to specify the required object.

3.2.3.8. Straight Line Tangent to Two Curves

To create a line tangent to two objects, call the **Straight Line Tangent to Two Curves command**.

Select the first and second objects with the cursor, to which the line should be tangent.

The ghosts of all possible tangency cases will be displayed.

Activate a suitable ghost and fix it.

Fig. 3.2.15. Straight lines tangent to ellipse and circle

To proceed to building lines tangent to other objects, click the **Reselect** button and proceed to select two objects.

3.2.3.9. Bisector

To build a bisector of an angle formed by two selected rectilinear objects, click **Bisector**.

Select any two rectilinear objects one by one.

The ghosts will be displayed of the bisectors of the angles made up by the selected objects.

Activate a suitable ghost and fix it.

If you select two parallel objects, the system will build a line equidistant from these objects.

To select other objects for building a bisector, click the **Reselect** button and proceed to select two rectilinear objects one by one.

Fig. 3.2.16. Bisectors of angles formed by a line segment and a polygon side

3.2.4. Line Segments

3.2.4.1. Line Segment

To draw an arbitrary line segment, click **Line Segment**.

Specify the start point of the line segment **p1**.

- ▼ If you know the location of the end point of the line **p2**, specify it. In this case, the length and inclination angle of a line segment will be determined automatically.
- ▼ If you know the length and tilt angle of the line segment, enter them in the relevant fields on the Property bar. The location of the end point will be defined automatically.

3.2.4.2. Parallel Line Segment

To draw a line parallel to a rectilinear object, click **Parallel Line Segment**.

Select an object to which the line segment should be made parallel.

Specify the start point of the line segment **p1**. The distance from the object to the parallel line segment will be determined automatically.

You can enter this distance in the relevant field on the Property bar before specifying the location of the start point of the line segment.

- ▼ If you know the location of the end point of the line **p2**, specify it.
- ▼ If the line segment length is known, enter its value in the Length field on the Property bar.

Fig. 3.2.17. Creating a line segment parallel to a rectangle side

To proceed to creating line segments parallel to another object, click the **Reselect** button and proceed to specify the required object.

3.2.4.3. Perpendicular Line Segment

To build a line segment perpendicular to a rectilinear object, click **Perpendicular Line Segment**.

Select an object to which the line segment should be made perpendicular.

Specify the start point of the line segment **p1**.

- ▼ If you know the location of the end point of the line **p2**, specify it.
- ▼ If the line segment length is known, enter its value in the Length field on the Property bar.

Fig. 3.2.18. Building a line segment perpendicular to a polygon side

To proceed to building line segments perpendicular to a different rectilinear object, click the **Reselect** button and proceed to select the required object.

3.2.4.4. Line Segment Tangent to Outside Point

To draw a line segment tangent to an object, click **Line Segment to Outside Point**.

Select the line to which the line segment should be tangent.

Then select the segment start point **p1** off the curve.

By default, the line end point is the tangency point. If necessary, you can modify the line segment length by entering the appropriate value in the respective field on the Property bar.

The ghosts of all possible line segments tangent to the given object and passing through the point **p1** will be displayed.

Activate a suitable ghost and fix it.

Fig. 3.2.19. Building line segments tangent to an arc

To proceed to building lines tangent to another object, click the **Reselect** button and proceed to select the required object.

3.2.4.5. Line Segment Tangent to Point on Curve

To draw a line segment tangent to an object and passing through a specified point on this object, click **Line Segment Tangent to Point on Curve**.

Select the object to which the line segment should be tangent. The arc ghost will be displayed.

- ▼ If you know the tangent point location, specify it.

And the value of the inclination angle and **p2** point coordinates of the tangent segment are determined automatically.

- ▼ If you know the inclination angle of the tangent line segment (the angle between it and the X-axis of the coordinate system), enter it in the **Angle** field on the Property bar.

Once the angle value is entered, ghosts for all variants of tangents positioned at a certain angle are displayed. Choose the appropriate variant of the tangent. For this purpose, move the cursor to the desired ghost. Once its respective tangent point appears on the screen, fix it by clicking on it with the mouse.

Fig. 3.2.20. Selection of tangent point

Select the point **p1** defining the segment length. If the tangent line segment length is known, enter its value in the **Length** field on the Properties bar.

Use snaps to position the cursor precisely (see Section 3.1.1.3 on p. 870) or the geometric calculator (see Section 3.1.2 on p. 871).

Fig. 3.2.21. Creating a tangent line segment:
a) specifying the tangent point, b) specifying the tilt angle

3.2.4.6. Line Segment Tangent to Two Curves

To draw a line segment tangent to two curves, click **Line Tangent to Two Curves**.
Select the first and the second curve, to which the line segment should be tangent.

By default, the system offers to create line segments with the end points in the tangency locations. If necessary, you can enter the desired line segment length value in the respective field on the Property bar.

The ghosts will be displayed for all possible segments tangent to the specified curves.
Activate a suitable ghost and fix it.

Fig. 3.2.22. Line segments tangent to an ellipse and circle

To proceed to building line segments tangent to other objects, click the **Reselect** button and proceed to select two curves with the cursor.

3.2.5. Circles

3.2.5.1. Circle

To draw an arbitrary circle, click **Circle**.
Select the circle centerpoint.

- ▼ If you know the location of the point **p** through which the circle passes, specify this point.

Fig. 3.2.23. Creating a circle by center and point

▼ If you know the value of the circle radius or diameter, enter it in the relevant parameter field on the Property bar. The system awaits diameter entry by default. In the **Parameter** group, the **Diameter** switch is active.

To enter the circle radius, activate the **Radius** switch.

3.2.5.1.1. Circle with Axes

By default, circles are built without axis lines. In this case, the **No Axes** switch is active in the **Axes** group on the property panel.

For the circle you are creating to have axis lines, activate the **With Axes** switch. Axes drawn along the directions of the current coordinate system will appear on the circle ghost.

Axes are created similarly when you build circles of other types.

If you have drawn a circle without axes but then discovered you need the axes as well, you do not need to delete the circle and create a new one with axes. Enter the circle editing mode by double-clicking the circle. Enable the drawing of axes and click the **Create Object** button on the Advanced Control panel.

You can also build axes using the **Center Mark** command (see Section 3.3.7.14 on p. 1048).

Axis lines represent a system macro element—the center mark. By default, the center mark is not linked with the circle and is not rebuilt during subsequent editing of the circle (changes made to the radius or location).

3.2.5.2. Circle by Three Points

To draw a circle passing through three specified points, click **Circle by Three Points**.

Specify the points **p1**, **p2** and **p3**, through which the circle should pass. The circle center coordinates and its radius will be determined automatically.

Fig. 3.2.24. Circle by Three Points

3.2.5.3. Circle with Centerpoint on Object

To draw a circle with a centerpoint on a specified curve, click **Circle Centerpoint on Object**. Select the object, to which the centerpoint of a circle should belong.

Specify the first point **p1** through which the circle you are creating will pass.

- ▼ If you know the location of the second point **p2** on the circle, specify it.

- ▼ If you know the value of the circle radius or diameter, enter it in the relevant parameter field on the Property bar. The system awaits diameter entry by default. In the **Parameter** group, the **Diameter** switch is active.

To enter the circle radius, activate the **Radius** switch.

The ghosts of all circle configurations satisfying the specified parameters will appear on the screen.

Activate a suitable ghost and fix it.

Fig. 3.2.25. Circles with centerpoints on the spline: a) passing through points **p1** and **p2**, b) with equal radii and passing through point **p1**

To proceed to building circles with a centerpoint on a different object, click the **Reselect** button and proceed to select a new object with the pointer.

3.2.5.4. Circle Tangent to One Curve

To draw a circle tangent to a selected curve, click **Circle Tangent to Curve**.

Select an object to which the circle should be made tangent.

- ▼ If you know the location of points **p1** and **p2** belonging to the circle you are creating, specify them (Fig. 3.2.26, a).

You can enter the circle radius or diameter in the relevant field on the Property bar before specifying the second circle point. However, building a tangent circle is possible not with all combinations of the point location on the circle (**p1**) and the radius value. If the circle ghost disappears after you enter the radius value, this means that building the circle is impossible.

- ▼ If you know the point of the circle center, enter it (Fig.3.2.26,b).

Ghosts of all circles with specified parameters and tangent to the selected curve will appear on the screen.

Fig. 3.2.26. Circles tangent to ellipse:
a) passing through points **p1** and **p2**, b) concentric

Activate a suitable ghost and fix it.

To proceed to building circles tangent to another object, click the **Reselect** button and proceed to select a new object with the pointer.

3.2.5.5. Circle Tangent to Two Curves

To draw a circle tangent to two selected curves, click **Circle Tangent to Two Curves**.

Select objects to which the circle should be made tangent.

- ▼ If you know a point **p** belonging to the circle you are creating, specify it.
- ▼ If you know the value of the circle radius or diameter, enter it in the relevant parameter field on the Property bar. The system awaits diameter entry by default. In the **Parameter** group, the **Diameter** switch is active.

To enter the circle radius, activate the **Radius** switch.

Ghosts of all circles with specified parameters and tangent to the selected curves will appear on the screen.

Select the intended ghost and fix it.

Fig. 3.2.27. Circles tangent to arc and spline:
a) passing through point **p**, b) of equal radii

To proceed to building circles tangent to other objects, click the **Reselect** button and proceed to select two objects with the pointer.

3.2.5.6. Circle Tangent to Three Curves

To draw a circle tangent to three selected curves, click **Circle Tangent to Three Curves**. Select the first, the second and the third object to which the circle should be tangent.

If there is an ellipse or spline among the selected objects, then you will need to specify an approximate circle position.

The ghosts will be displayed for all possible circles tangent to the specified objects. Activate a suitable ghost and fix it.

Fig. 3.2.28. Circle tangent to two ellipses and a line segment

To proceed to creating circles tangent to other objects, click the button **Reselect** on the Advanced Control Panel, and then select sequentially three objects using the cursor.

3.2.5.7. Circle by Two Points

To create a circle going through two specified points, click **Circle by Two Points**.

Specify the first point **p1** through which the circle will pass.

Enter the diameter or radius in the parameter entry field on the Property bar, when the **Diameter** or **Radius** switch is active.

Specify the second point **p2** through which the circle will pass.

If the points **p1** and **p2** are diametrically opposite, you do not have to enter the radius or diameter— it will be calculated automatically.

Fig. 3.2.29. Creating a circle by two points

3.2.6. Ellipses

When you build ellipses using all of the commands described below, the drawing of axis lines is controlled in the same way as when you are creating circles (see Section 3.2.5.1.1 on p. 910).

3.2.6.1. Ellipse

To draw an arbitrary ellipse, click **Ellipse**.

Specify the ellipse centerpoint.

Specify the value of the first ellipse semiaxis. This can be completed by the following methods.

- ▼ Specify the end point of semiaxis **p1**.
 - ▼ enter the semiaxis length into the relevant field on the Property bar.
- The tilt angle of the first semiaxis to the X axis of the current coordinate system is determined automatically.

If necessary, before specifying the value of the first semiaxis, you can specify the exact value of its tilt angle in the relevant field on the Property bar.

Specify the value of the second ellipse radius. You can also do this in two ways.

- ▼ Specify the end point of semiaxis **p1**.
- ▼ enter the semiaxis length into the relevant field on the Property bar.

Fig. 3.2.30. Ellipse by centerpoint and semiaxis dimensions

3.2.6.2. Ellipse by Diagonal of Circumscribed Rectangle

To draw an ellipse inscribed in a rectangle with a specified diagonal, click **Ellipse by Diagonal of Rectangle**.

In the respective field of the Property bar, enter the value of the ellipse's first semiaxis inclination angle with respect to the X-axis of the current coordinate system (by default, this value is 0°).

Then, select the start (**p1**) and end (**p2**) points of the diagonal of the rectangle circumscribed about the ellipse being created. The lengths of the ellipse's semi-axes will be calculated automatically.

Fig. 3.2.31. Ellipse by diagonal of circumscribed rectangle

3.2.6.3. Ellipse by centerpoint and vertex of circumscribed rectangle

To draw an ellipse inscribed in a rectangle with a specified centerpoint and vertex, click **Ellipse by Centerpoint and Vertex of Rectangle**.

In the respective field of the Property bar, enter the value of the ellipse's first semiaxis inclination angle with respect to the X-axis of the current coordinate system (by default, this value is 0°).

Then, select the centerpoint and a vertex of the rectangle circumscribed about the ellipse being created. The lengths of the ellipse's semi-axes will be calculated automatically.

Fig. 3.2.32. Ellipse by centerpoint and vertex of circumscribed rectangle

3.2.6.4. Ellipse by Centerpoint, Midpoint of Side and Vertex of Circumscribed Parallelogram Command

To draw an ellipse inscribed in a parallelogram with a specified centerpoint, midpoint and vertex, click **Ellipse by Centerpoint, Midpoint of Side and Vertex of Parallelogram**.

Specify the center point, and then the mid-side (**p1**) and the vertex (**p2**) of the parallelogram circumscribed about the ellipse being created.

The lengths of an ellipse's semi-axes and the inclination angle of its first semi-axis with respect to the X-axis of the current coordinate system will be calculated automatically.

Fig. 3.2.33. Ellipse by centerpoint, midpoint of side and vertex of parallelogram

3.2.6.5. Ellipse by Three Vertices of Circumscribed Parallelogram

To draw an ellipse inscribed in a parallelogram with three specified vertices, click **Ellipse by Three Parallelogram Vertices**.

Specify the positions of the vertices **p1**, **p2** and **p3** of the parallelogram circumscribed above the ellipse being created.

The lengths of an ellipse's semi-axes and the inclination angle of its first semi-axis with respect to the X-axis of the current coordinate system will be calculated automatically.

Fig. 3.2.34. Ellipse by 3 vertices of circumscribed parallelogram

3.2.6.6. Ellipse by Centerpoint and Three Points

To draw an ellipse with a specified centerpoint and passing through three specified points, click **Ellipse by Centerpoint and Three Points**.

Specify the location of the ellipse centerpoint and then points **p1**, **p2** and **p3**, which belong to it.

Fig. 3.2.35. Ellipse by centerpoint and 3 points

3.2.6.7. Ellipse Tangent to Two Curves

To draw an ellipse tangent to two specified objects, click **Ellipse Tangent to Two Curves**.

Specify the first and second objects at points **p1** and **p2** where they are tangent to the ellipse.

Use snaps to position the cursor precisely (see Section 3.1.1.3 on p. 870).

Specify the point **p3**, through which the created ellipse should go.

Fig. 3.2.36. Ellipse tangent to a line segment and circle

3.2.7. Arcs

This section is devoted to building circular arcs. Hereafter the word “circular” in the word combination “circular arc” will be omitted for brevity. The term “arc” should be understood to mean circular arc. Where other arc types are mentioned, e.g. ellipses, it will be stated specifically.

3.2.7.1. Arc

To draw an arbitrary arc, click **Arc**.

Set centerpoint of an arc.

Set starting point of an arc. You can do this by the following methods:

- ▼ select a point with the cursor,
- ▼ enter the angle and radius (or diameter) values in the relevant fields on the Property bar.

By default, the system awaits the radius value as you create a circle. In the **Parameter** group, the **Radius** switch is active.

To enter the diameter, activate the **Diameter** switch.

Set arc ending point. You can also do this in two ways:

- ▼ select a point with the cursor,
- ▼ enter the value of the end angle of the arc in the relevant field on the Property bar.

Fig. 3.2.37. Building an arc by centerpoint and two points

3.2.7.1.1. Selecting the Arc Direction

By default, the arc is built counterclockwise. In this case, the **Counter-Clockwise** switch is active in the **Direction** group on the Property bar.

To reverse the direction, activate the **Clockwise** switch.

The direction is set similarly when you build arcs of other types¹.

3.2.7.2. Arc by Three Points

To draw an arc with specified end points and a point on the arc, click the **Arc by Three Points** command.

Specify the arc start (**p1**), the point at which the arc should go (**p2**), and the arc end (**p3**) in any order. The arc center and its radius will be calculated automatically.

Fig. 3.2.38. Creating an arc by three points

3.2.7.3. Arc Tangent to Curve

To draw an arc tangent to a specified object, click **Arc Tangent to Curve**.

Select an object, to which the arc should be made tangent.

The **p1** point position, through which the arc should go.

Select the end point **p2** of the arc.

The arc center coordinates and its radius will be calculated automatically. Start point of arc is the tangent point.

You can enter the arc radius or diameter in the relevant field on the Property bar before specifying the point **p2**. However, building a tangent arc is possible not with all combinations of the point location on the arc (**p1**) and the radius value. If the arc ghost disappears after you enter the radius value, this means that building the arc is impossible.

The ghosts of all arc configurations satisfying the specified parameters will appear on the screen.

Activate a suitable ghost and fix it.

Fig. 3.2.39. Arc tangent to a line segment

To proceed to building arcs tangent to another curve, click the **Reselect** button and proceed to select a new reference curve with the pointer.

1. When you build an arc by three points, its direction is determined by the sequence in which you specified the points, which is why there will be no direction switch on the Property bar.

3.2.7.4. Arc by two points

To draw an arc with specified end points, click **Arc by 2 Points**.

Enter the radius or diameter value of the arc you are creating in the relevant field on the Property bar.

By default, the system awaits the radius value as you create a circle. In the **Parameter** group, the **Radius** switch is active.

To enter the diameter, activate the **Diameter** switch.

Specify the start point **p1** of the arc.

Select the end point **p2** of the arc.

To build an arc by diametrically opposite points, you do not have to enter the radius or diameter value; it will be determined automatically after you specify the points.

Fig. 3.2.40. Arc by two points

3.2.7.5. Arc by Two Points and Angle

To draw an arc beginning and ending at specified points and having a specific included angle, click **Arc by 2 Points and Angle**.

Enter the included angle value in the relevant field on the Property bar (the default value is 90°).

Specify the start point **p1** of the arc.

Select the end point **p2** of the arc.

The arc center coordinates and its radius will be calculated automatically.

Fig. 3.2.41. Arc by two points and angle 60°

3.2.7.6. Ellipse Arcs

KOMPAS-3D does not have a special command for building elliptical arcs. However, you can create elliptical arcs by applying trim commands (see Section 3.4.7 on p. 1137) to whole el-

lipses. Using snaps (see Section 3.1.2 on p. 871) and auxiliary elements (see Section 3.2.3 on p. 901), you can create elliptical arcs with specific parameters.

Fig. 3.2.42. Sample of elliptical arc obtained by trimming a whole ellipse at points **p1** and **p2**

Elliptical arcs are edited by means of handles (see Section 3.4.1.1.3 on p. 1114).

3.2.8. Rectangles and polygons

When you build rectangles and polygons with an even number of angles, axis lines can be drawn automatically. You can control the drawing of axis lines in the same way as when you create circles (see Section 3.2.5.1.1 on p. 910).

In KOMPAS-3D, rectangles and polygons are whole objects and not just sets of line segments. They are selected and edited wholly.

3.2.8.1. Rectangle

To draw an arbitrary rectangle, click **Rectangle**.

There are two methods of creating rectangles:

- ▼ By opposite two vertices.

Enable the **By two vertices** switch in the **Method** group of the Property bar. Specify the opposite vertices of the rectangle: **p1** and **p2**. If necessary, specify the rectangle's angle of slope in the **Angle** field. The rectangle's height and width are defined automatically.

Fig. 3.2.43. Creating a rectangle by opposites vertices

- ▼ By center and vertex.

Enable the **By center and vertex** switch in the **Method** group of the Property bar. Specify the rectangle's center and one of its vertices – **p1**. If necessary, specify the rectangle's angle of slope in the **Angle** field. The rectangle's height and width are defined automatically.

Fig. 3.2.44. Creating a rectangle by centerpoint and vertex

The angle of the rectangle's slope is counted from the X axis of the current coordinate system. By default, the angle is equal to zero.

In order to build a square, specify the second point keeping the `<Ctrl>` key pressed.

3.2.8.2. Rectangle by three points

In order to build a rectangle by three points, call the **Rectangle by three points** command.

There are two methods of creating rectangles:

▼ By three vertices.

Enable the **By three points** switch in the **Method** group of the Property bar. Specify the rectangle's vertices: **p1**, **p2** and **p3**. The rectangle's height, width and angle of slope are defined automatically.

Fig. 3.2.45. Creating a rectangle by three vertices

▼ By centerpoint, midpoint of a side and vertex.

Enable the **By center and two points** switch in the **Method** group of the Property bar. Set the rectangle's center, midpoint **p1** of a side and vertex **p2**. The rectangle's height, width and angle of slope are defined automatically.

Fig. 3.2.46. Creating a rectangle by centerpoint, midpoint of a side and vertex

3.2.8.3. Polygon

To draw a regular polygon, click **Polygon**.

By default a polygon is built by an inscribed circle. The relevant switch is enabled in the **Construction method** group. To enable the construction by a circumscribed circle, activate the **By Circumscribed Circle** switch.

Enter the number of the polygon vertices in the relevant field on the Property bar.

Specify the polygon centerpoint.

- ▼ If you know the location of point **p**, i.e., of one of the vertices (when building by a circumscribed circle) or midpoint of one of the sides (when building by an inscribed circle) of the polygon you are creating, specify this point.
- ▼ If you know the polygon radius or diameter as well as the tilt ¹angle enter them in the relevant fields on the Property bar.

By default, the system awaits entry of the diameter value upon circle parameter input. In the **Parameter** group, the **Diameter** switch is active.

To enter the radius, activate the **Radius** switch.

Fig. 3.2.47. Hexagon: a) by circumscribed circle, b) by inscribed circle

1. The polygon tilt angle is determined as the angle between the X-axis of the current coordinate system and the radius vector constructed from the polygon center into its first vertex (when constructing by the circumscribed circle) or into the middle of the first side (when constructing by the inscribed circle).

3.2.9. Polyline and splines

3.2.9.1. Polyline

To draw a polyline consisting of straight lines, click **Polyline**.

Specify polyline vertices.

Each vertex of the polyline is characterized by a set of parameters displayed in the **Vertex coordinates** table (see Section 3.2.9.1.1 on p. 923).

Fig. 3.2.48. Polyline: a) open, b) closed

Select an option of curve construction: closed or open. To do this, activate the desired switch in the **Mode** group: **Open object** or **Closed object**.

You can modify the polyline configuration without exiting the command. To do so, click the **Edit points** button on the Advanced Control Panel. The system will go into the object defining points editing mode. Make the required changes (see Section 3.2.9.1.2).

The created polyline is a whole drawing object. It will be selected, edited, and deleted entirely.

Fix the created polyline by clicking the **Create Object** button.

3.2.9.1.1. Table of Vertex Coordinates

Every vertex of a polyline or a spline is characterized by a set of parameters. Their values are displayed in the **Vertex Coordinates** table, which is located on the Properties Bar.

Each row of the table corresponds to a single vertex.

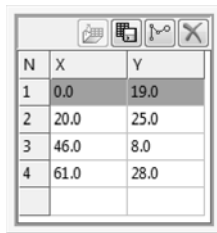

The following parameters are common for all splines and polylines:

- ▼ vertex number;
- ▼ vertex coordinates on axis X and axis Y.

When constructing a spline by points, the table displays both common parameters and ones dependent on the type of curve:

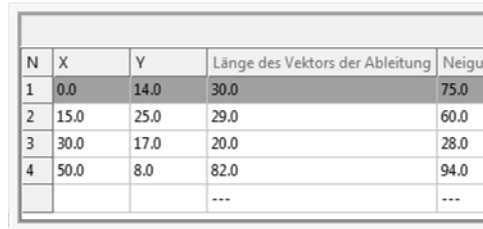

- ▼ NURBS-curve by points:
 - ▼ derivative vector length;
 - ▼ derivative vector slope angle;
 - ▼ curvature.
- ▼ Bezier Curve:

- ▼ length 1, 2 — lengths of the first and second derivative vectors;
- ▼ angle 1, 2 — slope angles of the first and second derivative vectors.

N	X	Y
1	0.0	19.0
2	20.0	25.0
3	46.0	8.0
4	61.0	28.0

a)

N	X	Y	Länge des Vektors der Ableitung	Neigung
1	0.0	14.0	30.0	75.0
2	15.0	25.0	29.0	60.0
3	30.0	17.0	20.0	28.0
4	50.0	8.0	82.0	94.0
			---	---

b)

Fig. 3.2.49. **Vertex Coordinates** table:
a) polyline and spline by poles, b) spline by points

The table rows are formed automatically during vertex construction in the document window. Editing a table row results in changed parameters of the respective vertex.

To change a vertex parameter, activate the respective cell in the parameters table by a double click and enter the new value in it. To move between cells, use arrow keys.

Above the **Vertex Coordinates** table are the following buttons used for working with parameters.

- ▼ **Read from file** — allows adding data stored in a file to the table. The button is available if the vertex parameters table is empty, i.e. right after the polyline/spline creation command is called. After the button is clicked a standard Select File dialog appears, where you need to select the desired fragment. The table of parameters will be filled in with the data from this file. The ghost of the spline constructed by the table data will appear in the document window.

- ▼ **Save to file** — allows saving the vertex parameters to a file for later use. Upon clicking this button, a standard Windows file save dialog will appear on the screen. In this dialog you need select a file name and the directory to save. By default the file shall be assigned the *txt* extension, but it can be changed if required. Coordinates can be saved to a file if at least one row in the table of parameters is filled.

- ▼ **Create new vertex** — allows creating a vertex next to an existing one. To do this, highlight a line with the number of the required vertex and click **Create New Vertex** or press the *<Insert>* key. In the document window a new vertex will appear. It will have the number of the current vertex plus one. Numbers of vertices starting from the one before which the new one was inserted will be increased by one. The newly created a vertex parameters line will be active.

- ▼ **Delete Vertex** — allows a vertex to be deleted. To do so, highlight the respective row of parameters and click **Delete Vertex** or press *<Delete>*. It is impossible to delete the last remaining row.

To perform actions with vertex parameters you can also use context menu commands of the **Vertex Coordinates** table.

3.2.9.1.2. Editing handles (when creating or editing an object)

You can change position, add or delete defining points of an object in the process of creation— after pressing the button **Edit Points** on the Advanced Control Panel.

In this mode, the defining points (handles) are displayed as small black squares in vertices, and the object is displayed as a ghost.

Move the cursor to a defining point that need to be edited. Shape of the cursor will change: it will turn into a four-sided arrow. Press the <Enter> key or click the left mouse button — the point will be selected.

You can edit object points as follows.

- ▼ **Point "dragging" with the mouse.**
- ▼ **Moving a point from the keyboard.**
For that, the point must be selected by pressing <Enter> key.
Move the cursor by the arrow keys.
- ▼ **Specify the Defining Point Coordinates.**
Specify new coordinates of the selected point on the Properties tab.
- ▼ **Adding or deleting a defining point.**
 - ▼ To add a point, click the mouse on the required segment of the object. It will be broken down into two parts by a new point in the specified location. You can move it to any position.
 - ▼ To delete a selected point, click the *Delete* button. This causes the defining point to disappear, and the object will be rebuilt according to the position of the remaining defining points.

When selecting a point position you can use the Snaps (see Section 3.1.1 on p. 865) and the Geometrical Calculator (see Section 3.1.2 on p. 871).

To exit the point editing mode and resume line constructing, release the **Edit Points** button.

3.2.9.2. Spline by poles

Spline by poles — a spline that goes through the extreme vertices tangent to outermost segments of the reference polyline and does not go through intermediate vertices (they are called the spine's "poles").

To construct a spline by poles, call the **Spline by poles** command.

Set spline vertices. To do so, specify the vertices of the reference polyline.

Each vertex of the spline is characterized by a set of parameters displayed in the **Vertex coordinates** table (see Section 3.2.9.1.1 on p. 923).

Set spline characteristics: spline order and weight of each handle. To do so, enter the required values in the fields **Order** and **Weight** on the Properties Bar. The order ranges from 2—10 whereas the weight falls between 0.0001—999.

For details on spline order and point weight refer to Section 2.5.1.4 on p. 329.

Fig. 3.2.50. Pole spline: a) open, b) closed

Select an option of spline construction: closed or open. To do this, activate the desired switch in the **Mode** group: **Open object** or **Closed object**.

You can change spline configuration without leaving the command dialog. To do so, click the **Edit points** button on the Advanced Control Panel. The system will go into the object defining points editing mode. Make the required changes (see Section 3.2.9.1.2 on p. 924).

Fix the created spline by clicking **Create Object**.

3.2.9.3. Spline by points

To construct a spline passing through given vertices call the command **Spline by points**.

Spline by points can be a curve of one of the following types:

▼ **Bezier Curve**

▼ **NURBS-point curve**

Select the required type of curve from the list **Curve Type** on the Properties Bar.

When constructing a NURBS-point curve select from the list **Method** on the Properties Bar the required method of forming parameters of spline points (see Section 3.2.9.3.2 on p. 928).

Set spline vertices. To do so, specify the points through which the spline will pass.

Each vertex of the spline is characterized by a set of parameters displayed in the **Vertex coordinates** table (see Section 3.2.9.1.1 on p. 923).

Fig. 3.2.51. Bezier Curve: a) open, b) closed

Select an option of spline construction: closed or open. To do this, activate the desired switch in the **Mode** group: **Open object** or **Closed object**.

To change spline configuration click the button **Edit Points** on the Advanced Control Panel. The system will go into the object defining points editing mode. In this mode you can:

- ▼ change the position and the number of vertices, see Section 3.2.9.1.2 on p. 924;
- ▼ change spline shape in a vertex:
 - ▼ Bezier curve — by controlling the length and direction of a derivative vector,
 - ▼ for a NURBS-point curve — by controlling tangency and curvature, see Section 3.2.9.3.1 on p. 927.

Fix the created spline by clicking **Create Object**.

All objects on drawings of the **Polyline and Splines** chapter have the same set of base points. You will notice the different shapes of objects having the same base points, depending on the object type and whether it is open or closed.

3.2.9.3.1. Controlling spline shape

When constructing a spline that is a NURBS-point curve, you can change its shape by controlling tangency and curvature in any vertex.

Tangency indicates how close is the spline's form to the tangent circle near its current vertex, curvature characterizes the radius of the circle (see Section 2.5.1.6 on p. 331 for more information about curvature and tangent circle).

Changing the spline's shape is possible in the object defining point editing mode for the current vertex. To enter the mode click **Edit Points** on the Advanced Control Panel.

After the mode is activated, the Properties Bar will have the list **Management** with spline management options in the current vertex.

Specify the vertex in which the spline shape needs to be changed in the document window or the **Vertex Coordinates** table.

Select the required option on the **Management** list:

- ▼ **Tangency** — allows setting the length and slope angle of the derivative vector in the selected vertex,
- ▼ **Tangency and curvature** — allows setting curvature, apart from the length and slope angle of the derivative vector.

After selecting one of management options, a notation of the option and managing ghost will appear next to the current vertex: one or two dashed arrows.

Set the parameters of the selected option using the Properties Bar or the managing ghost in the document window. Note that derivative vector length can only be set on the Properties Bar.

While in the spline shape management mode, you can also change the position of the current vertex by dragging it in the document window (see Section 3.2.9.1.2 on p. 924) or entering destination vertex coordinates in the parameters table (see Section 3.2.9.1.1 on p. 923).

After finishing editing the spline's form at one of vertices, you can:

- ▼ move to managing spline shape in another vertex — to do so, select the required vertex in the document window or in the table of parameters – the row with the number of that vertex,
- ▼ exit spline shape management mode — click **Edit Points** on the Advanced Control Panel,
- ▼ finish spline creation — click **Create Object**.

3.2.9.3.2. Methods of forming spline points

When constructing a spline that is a NURBS-point curve, you can select a desired curve parameterization method.

NURBS-point curve has parametric representation (see Section 2.5.1.2 on p. 327). The points used for creating the spline correspond to certain values of the parameter t . The shape of a spline passing the same points can be different (see Fig. 3.2.52). This depends on the method of forming spline point parameters:

- ▼ **Linear** — the values of the parameter that correspond to the user defined points are considered evenly distributed within the curve parametric range.
- ▼ **Chord length** — location of parameter values that correspond to user-defined points within the curve parametric range depends on the distance between neighboring points.
- ▼ **Centripetal** — location of parameter values that correspond to user-defined points within the curve parametric range depends on the square root of the distance between neighboring points.

Fig. 3.2.52. Splines with different methods of forming point parameters:
I – **Linear**, II – **Centripetal**, III – **Chord length**

To set a method of forming spline point parameters, select the required option on the **Method** list on Properties Bar.

3.2.10. Continuous Drawing of Objects

To draw a sequence of lines, arcs, and splines, click **Continuous Drawing of Objects**.

During the line input, an end point of the created object automatically becomes the start point for the next object. This command is convenient to use, for example, when creating a part contour consisting of objects of different types.

Fig. 3.2.53. Sample of sequence of objects created using the continuous drawing command

The created sequence is not a single object. Line segments will be selected, edited and deleted separately.

3.2.10.1. Creating Sequence Objects

After you click the command on the Property bar, the **Type** group will be displayed in addition to parameter entry fields. It contains switches that let you specify the type of a segment you are creating. To select a type, activate the relevant switch (see Table 3.2.2).

Tab. 3.2.2. Segment type switches

	Segment Type	Segment creation method
	Line	Arbitrary
		Parallel to an object
		Perpendicular to an object
		Tangent to an object
	Arc	By three Points
		Tangent
	Spline	Bezier Curve
		NURBS

By default, upon the first call of the command, the current type of object is **Line Segment**. This means that when you specify these points, the system will build a polyline consisting of lines that connect these points.

You can modify the current object type at any time while constructing the line. To do this, activate the desired speech in the **Type** group.

Ways to build various objects in the continuous drawing mode, as well as the techniques of controlling their parameters, are identical to the methods and techniques mentioned above for building individual objects.

3.2.10.2. Completing the Entry of Objects

The entry of objects can be completed by means of **Close** and **Draw New** switches on the Property bar.

Upon calling the **Close** command, a point that coincides with the first point of the sequence of objects is automatically created, and the sequence creation terminates. The automatically added point belongs to the object type, whose creation was active at the time of closing. If the number of already entered object points is not enough to automatically create an object to close the sequence, then the **Close** switch is inaccessible. After closing up the input sequence, the system waits for the input of a new continuous sequence of objects.

After activation of the **Draw New** switch, the drawing of a sequence is completed without closing and the system awaits entry of a new sequence.

3.2.10.3. Line Style during Continuous Drawing of Objects

The current style applies only to the object being formed and not to all objects in the sequence. This is why you can draw objects of different styles without interrupting the entry of the sequence.

3.2.11. Line

To draw a line consisting of line segments and/or circular arcs whose position can be either determined automatically by the system depending on the selected drawing objects, or specified by the user, click **Line**.

During the line input, an end point of the created object automatically becomes the start point for the next object.

The created sequence is not a single object. Arcs and line segments will be selected, edited, or deleted separately.

Two object types can be used to compose a line: a straight segments and an arc. You can modify the current object type at any time while constructing the line.

The method of constructing a straight segment or arc is determined by the system automatically depending on what objects are specified by the user. For example, if a straight object is specified when constructing a line segment, then the segment can be parallel or perpendicular to it. This is determined by the cursor motion direction.

When creating the first object in a sequence, there are additional construction methods, since this object, unlike the following ones, has none of its points fixed.

Ways to create the first objects of the line are described in Sections 3.2.11.2 on p. 932 and 3.2.11.4 on p. 936, and ways to create subsequent objects—in Sections 3.2.11.3 on p. 935 and 3.2.11.5 on p. 937.

The **Draw New** switch on the Property bar serves to terminate current line creation and start a new one.

Continuous Drawing of Objects switch lets you specify whether you will be creating individual objects or their sequence. By default, when the **Line** command is called for the first time, this switch is active and the start point of each subsequent object coincides with the end point of the previous one. To be able to define start points of objects arbitrary, disable the **Continuous Drawing of Objects** switch. To return to the chain creation, activate the switch again.

3.2.11.1. General Procedure of Building Line Objects

1. Specify the segment type by activating the relevant switch in the **Type** group on the Property bar:

▼ **Line segment,**

▼ **Arc.**

The current segment type of a line can be changed without referring to the Property bar by using the keys **<Ctrl> + <Tab>**.

2. Specify an object(s) for building a segment. For example, a line segment or arc can be tangent to a circle, a line segment can be parallel or perpendicular to a straight line or be located on an angle bisector, etc.

To select an object, move the cursor to it. When the object gets highlighted, left-click.

If you cannot select an object, verify that the **Point on Curve** snap is disabled. If the snap is enabled, disable it.

The failure to select an object when the snap is active is because the latter has a higher priority than the object selection.

To change the object, click the **Reselect** button on the Advanced Control panel. Highlighting will be cleared off the previously selected object, and you can select a new object.

After you select an object(s), a ghost will appear on the screen: a straight line or arc containing a segment.

3. Specify the start and (or) end points of the object. If the start (end) point is specified outside of the segment ghost, the location of the object start (end) is determined by projection of the specified point on the ghost.

While constructing segments of a line, the object parameter fields are displayed on the Property bar: the start and end point coordinates, the radius or diameter (for arcs), the length and angle (for line segments). These fields are used in the same way as when creating segments and arcs using the dedicated commands.

Ways of building line objects are detailed in chapters 3.2.11.2–3.2.11.5. In some cases, the sequence of actions may differ from the general procedure mentioned above.

After you create the object, the system waits to build the next object of the same type.

Note the following specifics of building line segments. In the cases when there are several possible methods to construct segments, the one is selected that is nearest to the selection point of the object. This is the difference between creating line segments and their counterparts created by dedicated commands. This approach helps speed up the construction, but requires a certain skill.

As we know, there are two variants of a line going through a given point and tangent to a circle. When constructing a line segment tangent to an arc by the **Line Tangent through Outside Point** command, you can select one of the tangency variants; you do not have a choice, however, when constructing a tangent segment as part of a line. The segment will be positioned on the line that is tangent to the circle at the point nearest to the circle selection point.

3.2.11.2. Ways to Build the First Line Segment

3.2.11.2.1. Parallel or Perpendicular to Object

To draw the first line segment parallel or perpendicular to another object, complete the following steps.

1. Use the cursor to select a straight object to which the line segment being created should be made perpendicular or parallel.
2. Set the start point of the segment.

The order of selecting a straight object and the start point of the segment doesn't matter.

3. Move the pointer across the document area. The line segment ghost will be displayed. Depending on the cursor position relative to the start point, the ghost may be parallel or perpendicular to the object. If the cursor is in area 1 (Fig.3.2.54, a), the line ghost is built parallel to the reference object (Fig. 3.2.54, b), and if it is in area 2, perpendicular to the reference object (Fig. 3.2.54, c).

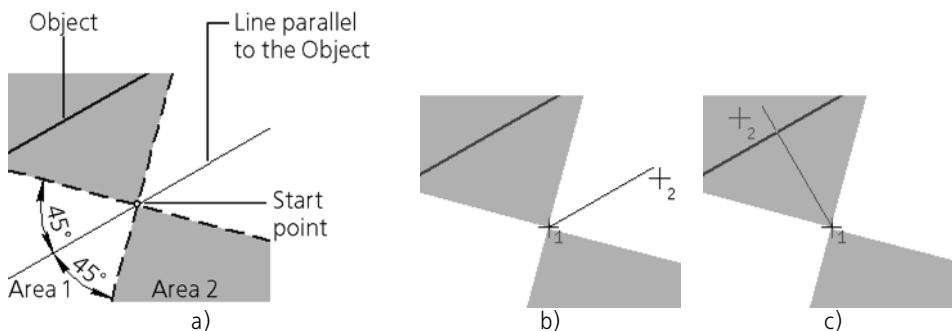

Fig. 3.2.54. Building a line parallel/perpendicular to a straight object

4. Move the cursor to set the desired segment direction and specify its end point.

3.2.11.2.2. Tangent to Object

To draw the first line segment tangent to an object, complete the following steps.

1. Use the cursor to select an curvilinear object, to which the line segment being created should be made tangent.
2. Move the pointer across the document area. You will see how the tangent line ghost follows the cursor.

To change the direction of the tangent to the circle (ellipse), move the cursor so as to cross the circle (ellipse).

3. Set the start and end point of the segment.

Fig. 3.2.55. Constructing of the first line segment tangent to another object:
a) selecting an object, b) selecting the segment start point, c) selecting the segment end point

To start (finish) the segment exactly at the tangency point, use the **Tangency** snap (see Fig. 3.2.59).

3.2.11.2.3. Tangent to One Object and Parallel to Another

To draw the first line segment tangent to an object and parallel to another one, complete the following steps.

1. Use the cursor to select an curvilinear object, to which the line segment being created should be made tangent.

Similarly, specify a straight object to which the second should be made parallel.

The sequence of selecting objects is not relevant.

2. Move the pointer across the document area. You will see how the tangent line ghost follows the cursor.
3. Set the start and end point of the segment.

Fig. 3.2.56. Constructing of the first line segment tangent to one object and parallel to another: a) specifying objects, b) specifying the start point of a line, c) specifying the end point of a line

To start (finish) the segment exactly at the tangency point, use the **Tangency** snap (see Fig. 3.2.59).

3.2.11.2.4. In between Two Parallel Lines

To draw the first line segment positioned on a line going in between two straight objects parallel to each other, complete the following steps.

1. Select the first and second straight object with the cursor.
2. Set the start point of the segment.
3. Move the pointer across the document area. A ghost segment will be displayed, positioned on a line centered between two selected straight objects.
4. Set the end point of the segment.

Fig. 3.2.57. Constructing the first line segment on a line centered between two parallel lines: a) selecting objects, c) selecting the segment end point

3.2.11.2.5. Tangent to Two Objects

To draw the first line segment tangent to two objects, complete the following steps.

1. Select the first and second curvilinear objects with the cursor, to which the segment being created should be made tangent.
- After selecting the second object, a ghost segment will be displayed, positioned on a line tangent to the selected objects at the points nearest to those, at which the objects were picked.
2. Set the start and end point of the segment.

Fig. 3.2.58. Constructing the first line segment tangent to two objects: a) selecting objects, b) selecting a segment start point, c) selecting the segment end point

To start (finish) the segment exactly at the tangency point, use the **Tangency** snap (see Fig. 3.2.59).

Fig. 3.2.59. Example of constructing the first line segment

3.2.11.2.6. On the Angle Bisector

To draw the first line segment positioned on the bisector of the angle between two straight objects, complete the following steps.

1. Select two straight nonparallel items with the mouse cursor.
2. Set the start point of the segment.

Move the pointer across the document area. A ghost segment will be displayed positioned on the bisector of the selected angle.

3. Set the end point of the segment.

Fig. 3.2.60. Constructing the first line segment positioned on an angle bisector:
 a) specifying objects, b) specifying the start point of a line,
 c) specifying the end point of a line

3.2.11.3. Ways to Build Subsequent Line Segments

3.2.11.3.1. Parallel or Perpendicular to Object

To draw a subsequent line segment parallel or perpendicular to another object, complete the following steps.

1. Use the cursor to select a straight object to which the line segment being created should be made perpendicular or parallel.
2. Move the pointer across the document area. The line segment ghost will be displayed. Depending on the cursor position relative to the start point, the ghost may be parallel or perpendicular to the object Fig.3.2.54 on p. 932).
3. Move the cursor to set the desired segment direction and specify its end point.

Fig. 3.2.61. Constructing a subsequent line segment perpendicular/parallel to another object: a) specifying an object, b) drawing a perpendicular line, c) drawing a parallel line

3.2.11.3.2. Tangent to Object

To draw a subsequent line segment tangent to an object, complete the following steps.

1. Use the cursor to select an curvilinear object, to which the line segment being created should be made tangent.
2. Move the pointer across the document area. You will see how the tangent line ghost follows the cursor. It is positioned on a line tangent to the selected object at the point nearest to the one at which that object was picked.
3. Set the end point of the segment.

Fig. 3.2.62. Constructing a subsequent line segment tangent to another object: a) selecting the object, b) selecting the segment endpoint

To finish the segment exactly at the tangency point, use the **Tangency** snap (see figures. 3.2.63).

Fig. 3.2.63. Example of constructing a subsequent line segment

3.2.11.4. Ways to Build the First Arc

3.2.11.4.1. Tangent to Object

To draw the first arc of the line tangent to an object, complete the following steps.

1. Set the start point of an arc.
2. Select an object, to which the arc should be made tangent.

3. Move the pointer across the document area. You will see how the arc ghost moves along. If you need to flip the arc direction, move the cursor through its start point.

The ghost is made tangent to the selected object at the point in which that object was selected. The arc radius is determined automatically and fixed.

 - ▼ To modify the radius, enter the desired value in the **Radius** or **Diameter** field on the Property bar.
 - ▼ To define the radius by specifying the end point, unfix the **Radius** or **Diameter** field, but do not enter a value.
4. Set the end point of an arc.

Fig. 3.2.64. Constructing the first arc of a line tangent to an object:
a) selecting the start point, b) selecting the object, c) selecting the end point

If the positions of the start and end point of the arc are fully constrained, then those uniquely define the arc radius. In this case, you can first specify the start and end point of arc, and then the object to which it should be tangent (Fig.3.2.65). The arc will be fixed with an automatically determined radius.

Fig. 3.2.65. Constructing the first arc of a line tangent to an object:
a) selecting the start and end point, b) selecting the object

3.2.11.4.2. Arbitrary

To draw the first arc arbitrarily, complete the following steps.

1. Set the start and end point of the arc. The arc ghost will be displayed.
2. Enter from the keyboard the arc radius or select with the mouse the point through which the arc should go.

3.2.11.5. Ways to Build Subsequent Arcs

3.2.11.5.1. Tangent to Object

A subsequent line arc can be drawn tangent to:

- ▼ previous line segment,
- ▼ previous segment and an arbitrary object,

▼ arbitrary object.

By default, the next arc in the line is constructed tangent to the previous segment. The segment is highlighted in the document window.

To build an arc tangent to a previous segment, perform the following steps.

1. If you know the arc radius or diameter, enter the required value in the **Radius** or **Diameter** field on the Property bar and fix it.
2. Move the pointer across the document area. You will see how the arc ghost moves along. If you need to flip the arc direction, move the cursor through its start point.
3. Set the end point of an arc.

Fig. 3.2.66. Building a subsequent arc tangent to a previous line segment

To build an arc tangent to a previous segment and an arbitrary object, perform the following steps.

1. Select the second object, to which the arc should be made tangent. It will be highlighted in the document window.
2. Move the pointer across the document area. You will see how the arc ghost moves along. The arc radius cannot be modified— it is fully constrained by the two objects to which the arc is tangent. If you need to flip the arc direction, move the cursor through its start point.
3. Set the end point of an arc.

Fig. 3.2.67. Constructing a subsequent arc of a line tangent to the previous segment and to an arbitrary object: a) object selection, b) specifying the arc endpoint

To build an arc tangent to an arbitrary object, perform the following steps.

1. Click the **Reselect** button on the Advanced Control panel. Highlighting will be cleared from the previous segment.
2. Select an object, to which the arc should be made tangent.
3. Move the pointer across the document area. You will see how the arc ghost moves along. It is made tangent to the selected object at the point in which that object was selected. The arc radius is determined automatically and fixed. To change the radius or diameter, enter the required value in the **Radius** or **Diameter** field on the Property bar. The ghost will rebuild.

If you need to flip the arc direction, move the cursor through its start point.

4. Set the end point of an arc.

Fig. 3.2.68. Constructing a subsequent line arc tangent to an arbitrary object: a) object selection, b) specifying the arc endpoint

3.2.11.5.2. Normal to the Previous Segment

A subsequent arc of a line can be drawn tangent to the normal to the previous line segment constructed at its end point. The tangency point is the start point of the arc. Construction of an arc normal to the previous segment is shown on Fig.3.2.69. The previous segment is drawn in a normal line, the dashed line is the normal to it at its end point, and the thin line is the arc along the normal.

Fig. 3.2.69. Arc by normal: a) to an arc, b) to a line segment

To proceed To drawing a normal arc, press the <Ctrl> key, move the mouse and release the key. You will see that the ghost arc rebuilds so as to be tangent to the previous segment normal constructed in its end point.

An arc by a normal can be tangent to an object or be arbitrary.

To draw an arc normal tangent to an object, complete the following steps.

1. Select an object, to which the arc should be made tangent. To do this, move the cursor to the desired object. When the object gets highlighted, left-click.
2. Move the pointer across the document area. You will see how the arc ghost moves along. The arc radius cannot be modified—it is fully constrained by the two objects to which the arc is tangent.

If you need to flip the arc direction, move the cursor through its start point.

If you need to change the object to which the arc is tangent, click the **Reselect** button on the Advanced Control panel. Highlighting will be cleared off the previously selected object, and you can select a new object.

3. Set the end point of an arc.

Fig. 3.2.70. Arc by a normal, tangent to an object:
a) object selection, b) specifying the arc endpoint

To draw an arbitrary normal arc, complete the following steps.

1. If you know the arc radius or diameter, enter the required value in the **Radius** or **Diameter** field on the Property bar and fix it.
2. Move the pointer across the document area. You will see how the arc ghost moves along.
If you need to flip the arc direction, move the cursor through its start point.
3. Set the end point of an arc.

Fig. 3.2.71. Constructing an arbitrary arc by a normal

A consequent arc of a line will also be constructed by a normal. To go back to drawing tangent arcs, press the <Ctrl> key, move the mouse and release the key. The arc ghost will rebuild.

3.2.11.5.3. Arbitrary

By default, the next arc in the line is constructed tangent to the previous segment. The segment is highlighted in the document window.

To cancel building a tangent arc, click the **Reselect** button on the Advanced Control panel. Highlighting will be cleared from the previous segment. Then, complete the following actions.

1. Set the end point of an arc. The arc ghost will be displayed.
2. Type in the arc radius or diameter in the **Radius** or **Diameter** field or click a point through which the arc should pass.

3.2.12. Multiline

3.2.12.1. General information

Multiline is a geometric object which consists of one or several lines built equidistant from the base line. Multiline may be used to draw piping, walls, partitions, fences, and other extended objects with a contour made of several lines (Fig. 3.2.72).

Fig. 3.2.72. Example of using multilines

It is not recommended to represent several objects with a single multiline (e.g. the group of parallel pipelines).

Lines in a multiline may have various styles.

The maximum number of lines in a multiline is 64.

All lines of a multiline are laid in one layer.

It is possible to change a configuration of a base line.

You can configure default multiline parameters in the setup dialog (see Section 9.2.6.9 on p. 1770) and also customize user parameters during multiline creation.

The multiline parameters can be saved in the multiline template file for further use. Using them you can create multilines of the same type.

Multiline may be included into a macroelement and a group.

3.2.12.2. Terms and Definitions

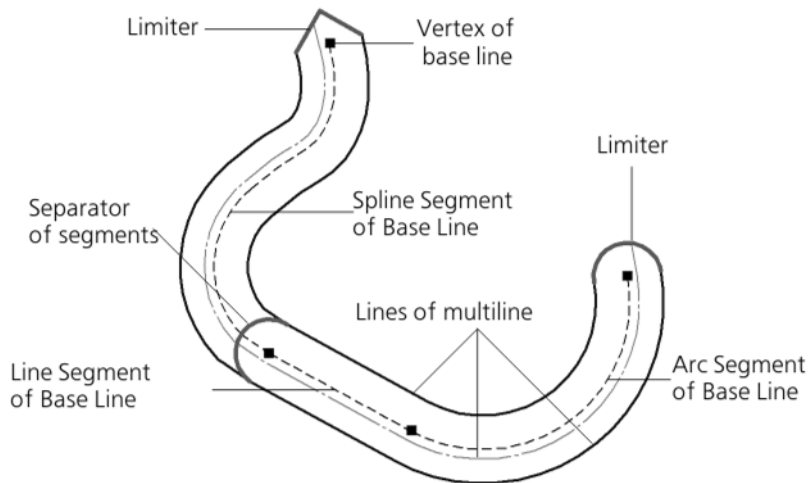

Fig. 3.2.73. Multiline (base line is shown as a dashed line)

Base line of a multiline— an invisible line of a multiline, the vertices of which are defined during the creation of a multiline and from which all other lines of the multiline are equidistantly built.

Segment of the base line of a multiline— a part of the base line between the neighboring vertices.

Line of a multiline— a complex geometric object consisting of successively connected linear, spline segments, circular, and elliptical arcs.

Segment of a multiline— a part of a multiline built based on one segment of the base line.

Multiline limiter— a line connecting end points of the outermost lines of the end multiline segment in a certain manner.

Separator of multiline segments— a line connecting the outermost lines of a multiline at the segment joint.

The **multiline's width** is the distance between the outmost lines of the multiline; the base line is not considered an outmost one. The width of a multiline consisting of a single line is equal to 0.

Multiline type— a set of the following multiline settings:

- ▼ Number of multilines and their settings— an offset from the base line and style;
- ▼ type of multiline limiters and their settings— height and style of a line

Same-type multilines— these are the multilines of one type. But the location of the base line vertices, their number, and separators of segments in the same-type lines may be different.

3.2.12.3. Creation of a multiline

To create a new multiline, call the **Multiline** command. The controls of multiline construction will appear on the Properties toolbar (Fig.3.2.74).

Fig. 3.2.74. Property toolbar for multiline construction

By default adding of segments to a multiline is switched on— **Add segment** button is depressed.

Specify the multiline parameters: number, offset and styles of lines. This can be completed by the following methods:

- ▼ define settings on the Property toolbar (See Section 3.2.12.4 on p. 943),
- ▼ get the settings from the multiline template (See Section 3.2.12.5 on p. 945),
- ▼ copy the settings of a previously built multiline (See Section 3.2.12.6 on p. 946).

Add the segments of the base line (see Section 3.2.12.6 on p. 946) and select the methods of passing the corner in vertices — variants of the multiline lines connection on segment joints (see Section 3.2.12.7 on p. 948).

The document window displays the ghost of the multiline being created. You can edit base line configuration directly while creating the multiline (see Section 3.2.12.10 on p. 952)— change vertex position and corner rounding method in it as well as add or delete a vertex. All changes made have an immediate effect on the multiline ghost.

Construction mode group of switches determines whether it's necessary to close a multiline. The multiline is closed by a straight segment.

A multiline comprising a single straight or spline segment cannot be closed.

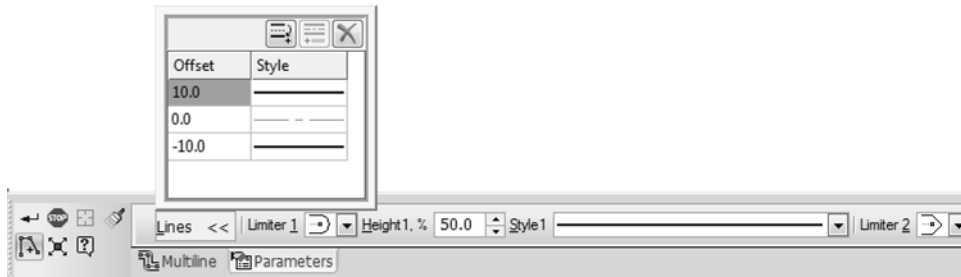

For open multiline you may define a type of limiters (See Section 3.2.12.8.1 on p. 951) and their settings: height and style of drawing lines (See Section 3.2.12.8.2 on p. 951).

To complete the creation of a multiline, click the **Create Object** button on the Special Control Panel.

3.2.12.4. Lines of a multiline

Multiline lines are listed on the **Lines** of the **Settings** tab (Fig. 3.2.75).

Fig. 3.2.75. Lines **Toolbar**

The styles of lines and their offset in relation to the base line are displayed in the list. The lines are listed in the ascending order of their offsets. Offset limits: from -50000000 to 50000000. The default line set is specified during the setup of multiline settings for new or current drawings (See Section 9.2.6.9 on p. 1770).

The **Lines** toolbar also contains buttons to control the lines. The description of the buttons is given in Table 3.2.3.

Tab. 3.2.3. Multiline lines control

The	Description
	<p>Create a new line Adds a new line to a multiline.</p> <p>After pressing the key the multiline is supplemented with a new line, and a new string containing the new line parameters is added to the list. The line has <i>Normal</i> style by default and a negative offset. Adding step is <i>10</i>. You may also add a new line by pressing the <i><Ins></i> key.</p> <p>To change an offset, enter the required value in the first field of the line, to change the style — select the required variant from the list in the second field.</p>
	<p>Create a symmetrical line Adds a line to the multiline which is symmetrical to the line highlighted in the list.</p> <p>After pressing the key the multiline is supplemented with a new line, and a new string containing the new line parameters is added to the list. The added line has the style of the highlighted line and its offset with an opposite sign. The new line on the list has a position corresponding to its offset.</p> <p>The button is unavailable if in the list there's selected the line that already has a symmetrical one or if the selected line has zero offset.</p>

Tab. 3.2.3. Multiline lines control

	The	Description
	Delete line	<p>Deletes the line highlighted in the list from the multiline. After pressing the key the highlighted line will be deleted from the multiline and from the list.</p> <p>You can also delete the line by pressing the <code><Ctrl>+<Delete></code> key combination.</p> <p>The key is not available if there is just one line in the list or if all lines are highlighted.</p>
		<p>Degenerate lines of a multiline are not displayed in a document. If such lines appear in a multiline a message flashes on the screen to signal that it will be impossible to display them. Degenerative lines are not removed from the multiline— they are seen in the list of multilines on the Lines toolbar of the Settings tab. If the form of the baseline and/or values of offsets are changed, these lines become visible.</p> <p>If all lines become degenerative during the multiline construction, only the ghost of the basic line will be displayed, and the Create object button will become unavailable.</p>

3.2.12.5. Multiline template

The multiline parameters can be saved in the multiline template file for further use. A template file has *mlt* extension.

Templates of multilines are located in the folder defined by the KOMPAS-3D environment variable MULTILINETEMPLATES. By default, this folder is *\Templates* in the main system installation folder. In order to define another folder for multiline templates, create and edit the *KOMPAS.ini* file (for more information about the KOMPAS-3D environment's variables, see Section 9.5.4 on p. 1886; for more information about *KOMPAS.ini* file see Section 9.5.3).

The multiline's template contains the parameters of the multiline:

- ▼ the number of lines and their parameters: style and displacement from the base line;
- ▼ the types of limiters on the multiline ends and their parameters: the limiters height and the lines' style.

To save settings of the current multiline, press the **Save template** button in the **Settings** tab of the Properties toolbar. Windows-standard File Save dialog will be displayed. Enter a template name and click the **Save** button.

To use the template in creation and editing of a multiline, press the **Load Template** button in the Settings tab of the Properties toolbar. The standard File Open dialog will appear on the screen. Select a file name and click the **Open** button. The multiline will receive parameters from the template. The multiline's ghost will be changed in line with the obtained parameters.

If required, you may edit the settings received from the multiline template (See Section 3.2.12.4 on p. 943 and Section 3.2.12.8 on p. 951).

If the message *Cannot open file* pops up during the template loading, this means that the selected file is not a template or the template file is incorrect.

3.2.12.6. Base line

The base line of a multiline consists of segments.

The group of switches **Type** (Fig.3.2.76) allows to select type of the segment to be added to the base line:

Straight-Line Segment or **Arc Segment** (see Section 3.2.12.6.1 on p. 946);

Segment by Object (see Section 3.2.12.6.2 on p. 946).

Fig. 3.2.76. The group of switches **Type**

You can add segments to the base line when creating and editing a multiline.

3.2.12.6.1. Straight-line and arc segments

Straight-line and arc segments can be added to the base line by constructing them directly during the creation (or editing) of the multiline.

To add a straight-line or arc segment, enable the required switch in the **Type** group: **Straight-line Segment** or **Arc Segment**. Build a segment of the base line. The procedure for construction of the straight-line and arc segments is similar to that for the line objects (See Section 3.2.11.1 on p. 931).

Please, pay attention to the following features of construction of base line segments.

- ▼ By default an arc segment is made on the tangent to the previous segment of any type.
- ▼ By default the straight-line segment is made on the tangent to the previous arc segment.

To cancel the construction of the segment on the tangent to the previous segment, press the **Define Again** key on the Special Control Panel. You may then randomly construct an oriented segment of the base line.

The segment adding is reflected in the ghost of the multiline.

After the segment adding the system will wait for the following segment of the same type. The end vertex of the created segment will automatically become a start vertex of the following segment.

3.2.12.6.2. By Object Segment

The opened geometrical object previously created in the graphical document may be added to the base line.

- ▼ segment;

- ▼ arc of a circle or ellipse;
- ▼ NURBS, Bezier curve or polyline;
- ▼ contour;
- ▼ multiline.

To add the opened geometrical object to the base line, activate the **Segment by Object** switch in the **Type** group.

Define an object to add to the base line. To do this, move the cursor to it. When the object gets highlighted, left-click.

If the multiline already has segments, the object adding is possible only if the end vertex of the last segment matches the start or end point of the added object.

Several successively connected objects may be added to the base line. These objects should be specified by their location order.

The Bezier curve, NURBS and the polyline should be added to the base line in whole. The Bezier curve or NURBS is added as one segment, the polylines added as several segments the number of which is equal to the number of the polyline segments.

You may define another multiline as an object. In this case the base line will be added with all segments of the defined multiline with its specified methods of passing the corner in the base line vertex (See Section 3.2.12.7 on p. 948).

To cancel the object selection, press the **Cancel** button on the **Standard** bar.

Control Mode group switches specify whether to leave initial objects after they've been added to the base line.

3.2.12.6.3. Base line modification

After the multiline is built, its base line may be added with straight-line or arc objects using the **Chamfer on Object Corners** (See Section 3.2.15.2 on p. 972) and **Fillet on Object Corners** (See Section 3.2.15.4 on p. 973). Vertices of new segments will have default settings — the corner passing with cut without a segment separator (See corner passing methods in Section 3.2.12.7 on p. 948).

Besides, you can add a segment at the beginning and/or in the middle of the base line of the multiline by splitting this multiline into parts and creating a new one from a new segment (segments) and parts of the original multiline.

For instance, the document has a multiline built with vertices A, B, C, D (Fig. 3.2.77, a). Add curves at the beginning and in the middle (between vertices B and C) of this multiline (Fig. 3.2.77, b).

Fig. 3.2.77. Adding segments to the multiline:
a) initial multiline; b) result of addition

For this, do the following.

1. Divide the multiline into three sections in vertices B and C. For this, use the **Divide curve** command.
2. Remove the BC section.
3. Build a curve of the required form.

The end point of the curve should match the start point of A multiline.

4. Build the second curve.

The start and end points of the curve should match B and C vertices.

5. Call the **Multiline** command.
6. Copy the initial multiline properties to the new multiline.
 - 6.1. Press the **Copy Properties** button on the Special Control Panel.
 - 6.2. Specify the properties source in the document window— any of the parts of the initial multiline.
7. Add built objects and parts of the initial multiline to the base line of the new multiline.

- 7.1. In the **Type** group enable the **Segment by Object** switch.
- 7.2. Specify objects to be added to the base line: built objects and parts of the initial multiline. These objects should be specified by their location order.

To remove the initial objects during the construction, enable the **Remove Initial Objects** switch in the **Construction Mode** group of **Settings** tab.

3.2.12.7. Methods of passing the corner in a vertex

The method of passing the corner in the base line vertex— is a method of connection of the multiline lines in the segment joint. There are three methods of corner passing (Fig.3.2.78): passing with cut (See Section3.2.12.7.1 on p. 949), passing via fillet (See Section3.2.12.7.2 on p. 950), passing via fillet with equal radius (See Section3.2.12.7.3 on p. 950).

Fig. 3.2.78. Methods of passing the corner in the base line vertex: a) passing with cut, b) passing via fillet c) passing via fillet with equal radius

- ▼ When creating a multiline, the method of vertex tracing is defined for the start vertex of the segment being added. The defined method is used by default for the subsequent vertices.
- ▼ When editing a multiline, you can define the required method of tracing for any vertex of that multiline except the end vertices.

To select the corner passing method use the **Corner Passing** group of switches on the **Multiline** tab of the Properties toolbar.

To define the required corner passing method enable the required switch: **With cut**, **With fillet**, **Via fillet with constant radius**.

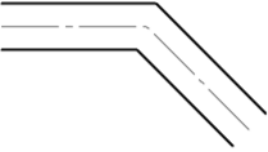

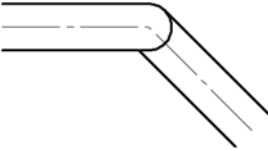

3.2.7.1. Passing with Cut

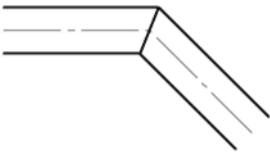

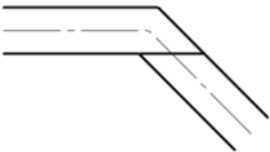

The **Passing with Cut** method allows to insert the separator in the joint of the multiline segments.

To select the required separator, open the **Separator** list in the **Multiline** tab of the Properties toolbar and specify the required line in it (Table 3.2.4).

Tab. 3.2.4. Separators of multiline segments

Delimiter	Symbol
	Without separator 
	Arc 

Tab. 3.2.4. Separators of multiline segments

Delimiter	Symbol
	<p>Angular</p> 
	<p>Overlapping</p> 

For the **Arc** and **Overlapping** separators you can define a direction, i.e. select the one of the two segments to be joined for which a separator will be created.

To select the separator direction use the **Direction** group of switches.

To define the required separator direction enable the required switch: **Direction 1** or **Direction 2**.

The drawing up line of the separator has the *Normal* style by default. Use the **Style** list on the Properties toolbar to change the line style. The list is unavailable if there is no limiter at the segments joint.

Please, note that if the drawing up style of the arc separator differs from the style of outermost lines of the multiline, the joint of the segments will look as shown on Fig. 3.2.79.

Fig. 3.2.79. Segment joint with the arc separator

3.2.12.7.2. Passing via fillet

The **Passing via Fillet** method connects the multiline lines in the segment joints by rounding them off with the equidistant radius.

3.2.12.7.3. Passing via Fillet with Equal Radius

The **Passing via Fillet with Equal Radius** method connects the multiline lines in the segment joints by rounding off. The fillet radius is the same for all lines. By default, the fillet radius is equal to 10.

Enter the required fillet radius in the **Radius** field or define it using the counter.

3.2.12.8. Multiline limiters

The default view and settings of limiters are defined during the multiline setup (see Section 9.2.6.9 on p. 1770). You may change the view of the multiline end segment limiter (See Section 3.2.12.8.1 on p. 951) and its settings: the height and style of the drawing up line (See Section 3.2.12.8.2 on p. 951).

After editing the limiters may stop displaying in the document. This occurs in the following cases:

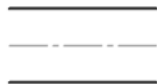

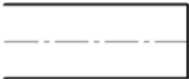

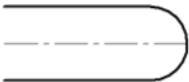

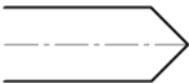

- ▼ one line has been left in the multiline;
- ▼ neither outermost line is displayed in the multiline.

Information of the non-displaying limiters is saved in the multiline.

3.2.12.8.1. Selection of the multiline limiter view

To define a limiter view, define the required line on the **Limiter 1** (or **Limiter 2**) line in the **Settings** tab of the Properties toolbar (Table). 3.2.5).

Tab. 3.2.5. Multiline limiters

Limiters	Symbol
 Without limiter	
 Straight-line	
 Arc	
 Polyline	

3.2.12.8.2. Definition of the limiter settings

To define the limiter height, enter its value in the **Height 1, %** (or **Height 2, %**) field of the **Settings** tab of the Properties toolbar. This parameter's value is set as percentage, from 0 to 100, of the multiline's width.

To change the line style, use the **Style 1** (or **Style 2**) list on the Properties toolbar.

Please note that if the drawing up style of the straight-line limiter differs from the style of the multiline outermost lines, depending on the height value the limiter will look as shown in Fig. 3.2.80.

Fig. 3.2.80. Straight-line limiter:
a) with zero height; б) with the height greater than zero

3.2.12.9. Multiline Operation Modes

During the multiline creation the segment adding mode is enabled by default — the **Add Segments** button on the Special Control Panel is pressed. In this mode a base line is created, multiline settings are defined and methods of passing the corner in the multiline vertex are selected (See Section 3.2.12.3 on p. 942).

The second mode of working with the multiline— item editing mode. In this mode you may change position of the base line vertices (see Section 3.2.12.10.1 on p. 953) and insert new vertices in it (see Section 3.2.12.10.2 on p. 954). In this mode you may also change multiline settings (See Sections 3.2.12.4 on p. 943, 3.2.12.7 on p. 948 and 3.2.12.8 on p. 951). To switch to the editing mode, press the **Edit items** button on the Special Control Panel. Vertices of the base line in the form of small black squares appear on the multiline ghost.

The **Edit Items** button is available if the multiline has at least one segment.

You may switch between the modes of segments adding and editing using the Special Control Panel buttons or commands in the context menu.

By default, when you edit the already created multiline, the element edit mode is enabled automatically.

3.2.12.10. Vertex editing

When needed, you may reconfigure the base line of the multiline by editing its vertex.

Base line vertices shall be edited in the multiline element edit mode (the **Edit Elements** button is pressed on the Special Control Panel). The multiline operation modes are detailed in Section 3.2.12.9 on p. 952.

The group of switches **Operation** (Fig. 3.2.81) allows to select the baseline vertex edit operation:

- ▼ **Vertex Editing** is a change in position, parameters or deletion of a vertex (see Section 3.2.12.10.1 on p. 953);

- ▼ **Vertex Insertion** (see Section 3.2.12.10.2 on p. 954).

Fig. 3.2.81. The group of switches **Operation**

3.2.12.10.1. Vertex editing operation

Vertex editing operation allows:

- ▼ changing the vertex position;
- ▼ removing the vertex;
- ▼ defining the method of passing the corner in a vertex, if this vertex is not an end one (See Section 3.2.12.7 on p. 948).

To edit a vertex, enable the **Edit Vertices** switch in the **Operation** group.

Vertex defining

Move the cursor to the required vertex. The cursor shape will change—it will turn into a four-pointed arrow. Left-click the mouse. The vertex will be activated—its color will change from black to that defined for highlighted objects (see Section 9.1.7.11 on p. 1713).

To cancel the selection, click outside the multiline ghost.

Vertex moving

Define a vertex. Change its position moving the mouse or defining new coordinates (See below). Besides, for this vertex you may define the required method of corner passing (See Section 3.2.12.7 on p. 948).

Defining vertex coordinates

Define a vertex. On the Properties toolbar beside the **Operation** group there are fields with coordinates of this vertex. Enter new values in the coordinate fields and fix them by pressing the **<Enter>** key. After that the highlighted vertex will take a new position.

Vertex removal

Define the vertex and press the **<Delete>** key. The vertex will be removed and the multiline will be reconstructed.

- ▼ During the removal of the multiline end vertex, the segment corresponding to it will be removed.
- ▼ During the removal of any other vertex of the multiline the segments adjoining it will be removed. A straight-line segment will be inserted in the multiline instead.

After the removal of one-segment multiline vertex the system will switch to segment adding mode.

3.2.12.10.2. Vertex Insertion operation

Operation of the vertex insertion into the base line adds a new vertex to the base line.

To add a new vertex to the base line, enable the **Insert Vertex** switch in the **Operation** group.

Insert a new vertex into the base line.

You may define the insertion point for the new vertex with the cursor on the multiline ghost. If the indicated point does not belong to the multiline, the position of the new vertex will be defined by the projection of a point on the base line.

To create a new vertex enter its coordinates into the fields located in the Properties toolbar. The entered coordinates should be confirmed by pressing the *<Enter>* key.

For the new vertex the current corner passing method will be used (see Section 3.2.12.7 on p. 948).

3.2.12.11. Deleting and Restoring segments of multilines

After multiline creation, the **Trim Line** and **Trim Line by 2 Points** commands can be used for its lines (see Sections 3.4.7.1 on p. 1137 and 3.4.7.2 on p. 1138). As a result of executing these commands, the multiline segments will be deleted.

If necessary, you can restore deleted segments of multilines by two methods.

1. To restore one or several deleted segments, call the **Restore deleted multiline's segment** button from the **Editor** menu or press the same-name button on the **Editing** toolbar.

Move the cursor to one of the outermost points of the segment that should be restored. Selected portion will be highlighted. After the mouse click, this portion will be restored. You can restore arbitrary number of portions by sequentially selecting them with cursor.

If you need to restore several deleted segments of multilines or several multilines, it is convenient to use selecting by marquee frame. To select a portion using this method, it is sufficient that one of its end points was inside marquee frame. All segments specified by the marquee frame are highlighted and restored after the frame is formed.

2. To restore all deleted segments of multiline, call the **Restore Multiline Line Integrity** button from the **Editor** menu or press the same-name button on the **Editing** toolbar.

Point the cursor to the multiline line which integrity you need to restore. Selected line will be highlighted. After the mouse click, all the deleted portions of this line will be restored. You can restore integrity of arbitrary number of portions by sequentially selecting them with cursor.

If you need to restore integrity of all lines of a multiline or several multilines, it is convenient to use specification by a cutting segment (see Section *Specifying a group of objects with a cutting segment* on page 357). The selected lines are highlighted. After forming cutting segment, deleted portions of all selected lines are restored.

Multilines that contain deleted portions can be selected in the document window before calling the Restore Multiline Line Integrity command. In this case, a prompt to restore all deleted parts of these multilines appears on the screen after calling the command. To restore the deleted segments, click the **OK** button. The **Cancel** button serves to reject the restoring.

Further working with the command is described above.

3.2.12.12. Multiline editing features

Use all editing commands except the **Align along Border**, **Extend to Nearest Object**, **Clear Area**, **Transform into NURBS** commands. See a detailed description of editing commands in Section 3.4 on p. 1113.

The multiline may be used as a limiting object in commands **Align along Border** and **Extend to Nearest Object**.

Besides, you may split the multiline into separate objects. For this use the command **Editor – Destroy**.

The command **Remove Facet or Fillet** (See Section 3.4.7.5 on p. 1140) removes an arc or straight-line segment of the multiline provided that the remained segments may be extended up to the intersection point.

3.2.13. Hatch and Fill

Hatching and filling areas of a graphic document with color in KOMPAS-3D is similar to the way you build objects.

To create a hatch or fill, you have to specify its border and parameters. The methods of specifying borders, which are the same for hatches and fills, are described in Section 3.2.13.1, techniques of creating hatches— in Section 3.2.13.2 on p. 958, techniques of creating fills — in Section 3.2.13.3 on p. 959.

3.2.13.1. Specifying Borders

The number and numbering level of areas specified at the same time are unlimited.

The objects limiting the hatch (fill) can be selected before the command is executed. In this case, after you execute the command, the system will display a request for the use of selected objects as the hatch (fill) boundary. To confirm, click **Yes**, and the system will immediately build a hatch (fill), if possible.

If no objects were selected or if you chose not to use them, specify a point within the area you want hatched (filled). The system will determine the immediate border within which the point has been specified and create a hatch (or fill) ghost.

The borders of hatch and fill may be system lines of styles *Normal* and *Broken Line* or user style lines during configuring which it was defined that they can be used as hatch borders.

Fig. 3.2.82. Constructing a hatch:
a) points within the areas selected for construction, b) resulting hatch

Specifying a point within an area is the default way to specify the hatch (fill) border. You can also form the border manually or with an arrow. These methods are detailed below.

When you create associative hatches or fills (for associative objects see Section 7.2.1.4 on p. 1602) the modes of drawing borders manually or tracing borders by arrow are inaccessible.

In addition, you can specify the hatch (fill) of existing geometric objects as a border for a new hatch or fill. The commands **Add Border** and **Remove Border** in the context menu are intended for this purpose. Each of them opens a submenu with the list of ways to specify objects.

If the hatch (fill) in several non-connected areas of the document should have similar settings, it should be created as a single object.

For example, the borders of **all hatch areas** of a part section (Fig. 3.2.83) should be specified as borders of the **same hatch**. This will ensure the hatch parameters inside them are identical and simplify further editing.

Fig. 3.2.83. Hatch consisting of several areas

3.2.13.1.1. Manual Drawing of Borders

Drawing borders manually means specifying manually the border of an area where a certain operation will be performed. Borders drawn in this way are displayed only until the command is completed.

To switch to the manual border drawing mode, press the button **Manual Drawing of Borders**.

The set of control elements on the Property bar will change; it will look as shown in Fig.3.2.84.

Fig. 3.2.84. Property bar in the manual border drawing mode

Sequentially select polyline vertices bounding the region.

Switches of the **Mode** group let you control the closing of a polyline.

You can change the position of polyline vertices directly in the process of drawing. To do this, click the **Edit Points** button.

Move the pointer to any handle (displayed as black squares). Shape of the cursor will change: it will turn into a four-sided arrow.

Change the position of handles by an way or delete unnecessary points, similar to editing a polyline (see Section3.2.9.1.2 on p. 924)

You can also add handles. To do this, click the required segment. The selected segment will be divided into two pieces by the new vertex that will be positioned at the specified point. You can “drag” it to any position.

To exit the mode of editing the handle positions, release the **Edit Points** button.

When done drawing the border, press the **Create Object** button.

To cancel manual drawing of the border, press the <Esc> key or the **Interrupt Command** button.

3.2.13.1.2. Trace Border by Arrow

Tracing the border by arrow means specifying the border of an area where you want to perform any operation by tracing intersecting geometric objects.

To switch to the mode of border tracing by arrow, click the button **Border by Arrow Direction**.

The set of control elements on the Property bar will change; it will look as shown in Fig.3.2.85.

Fig. 3.2.85. Property bar in the mode of border tracing by arrow

Select a point near a geometrical object, from which you need to start traversing the contour.

A ghost image of the first contour segment is displayed (overlaid on the base element), and an arrow indicating the system-proposed direction to move in.

To define the necessary direction, click with the mouse on the appropriate object.

You can also select the direction of movement by contour segments using the following buttons on the Special Control panel:

▼ **Previous Direction,**

▼ **Next Direction,**

▼ **Step Forward,**

▼ **Step Backward.**

In addition, you can change the movement direction using keyboard shortcuts listed in Table 3.2.6.

Tab. 3.2.6. Keyboard shortcuts for selecting the tracing direction

Key	Description
<Space>	Choosing among the possible continuation directions from the current node counterclockwise.
<Shift>+<Space>	Choosing among the possible continuation directions from the current node clockwise.
<Enter>	Confirmation of the choice of direction marked with the arrow.
<Shift>+<Enter>	Go one step back.

 Group of switches **Node Passing Mode** lets you specify in what way you will pass nonbranching nodes of the contour, i.e., nodes in which there is only one movement direction (meaning that the node has no branches). By default, automatic processing of such nodes is used (without a prompt to select the direction to continue).

 To reject tracing the border and start forming the contour anew, click **Reselect** and specify the required object from which you want to start tracing.

When you specify a section that closes the contour, i.e., a section whose end point coincides with the start point of the first section, the object becomes fixed automatically.

 To fix an open contour, click the **Create Object** button.

 An open contour existing in a graphic document can be selected as a hatch border only using the method of border tracing by arrow.

3.2.13.2. Hatch

3.2.13.2.1. Creating Hatches

You hatch one or several areas, click **Hatch**.
Specify hatch borders and parameters.

The hatch ghost will appear, enabling you to control whether you have selected hatch areas and parameters correctly.

When all the required areas are hatched, click the **Create Object** button. The hatch will be fixed in the document, and the system will wait for you to specify the border for the next hatch.

3.2.13.2.2. Hatch Parameters

Hatch parameters can be configured using control elements on the **Hatch** tab of the Property bar. They are represented in Table 3.2.7.

Tab. 3.2.7. Hatch control elements

Element	Description
Style	List of hatch styles. To change the current hatch style, open the list and select the required style.
Color	The list lets you select the color of hatch (or fill) lines. Clicking the Another Color item displays the advanced dialog of the color selection.
Base point	A conventional start point for the hatch. When changing its coordinates, hatch lines move vertically or/and horizontally.
Step	Hatch spacing.
Angle	Hatch rotation angle around the datum point.
Type	
	Hatching the entire area inside the border.
	Creating a hatch as a band along the border.
Width*	Value of the hatch band thickness.
Position*	
	Location of the hatch band to the left of the border.
	Location of the hatch band to the right of the border.

* This control element is available if the **Band** switch is active in the **Type** group.

3.2.13.3. Fill

3.2.13.3.1. Fill Types

Fills of the following types can be created in KOMPAS-3D.

- ▼ **Monochromatic** fill representing a solid color fill of a selected area.
- ▼ **Gradient** fill with a gradual or step-by-step color variation, comes in several types (linear, cylindrical, angular, conical, radial and square) and gives a third dimension effect to images in a graphic document (see Fig. 3.2.86).
- ▼ The fill area can consist of one or several closed contours, including disconnected contours.

Fig. 3.2.86. Example of using fills

The following specifics have to be considered when creating gradient fills.

After you have specified one or several fill areas around contours, the system automatically creates a **dimensional rectangle** inside which color distribution will occur. When you change fill parameters, such as the fill angle, the dimensional rectangle will also change (see Fig. 3.2.87). The dimensional rectangle is conventional and is not displayed on the screen.

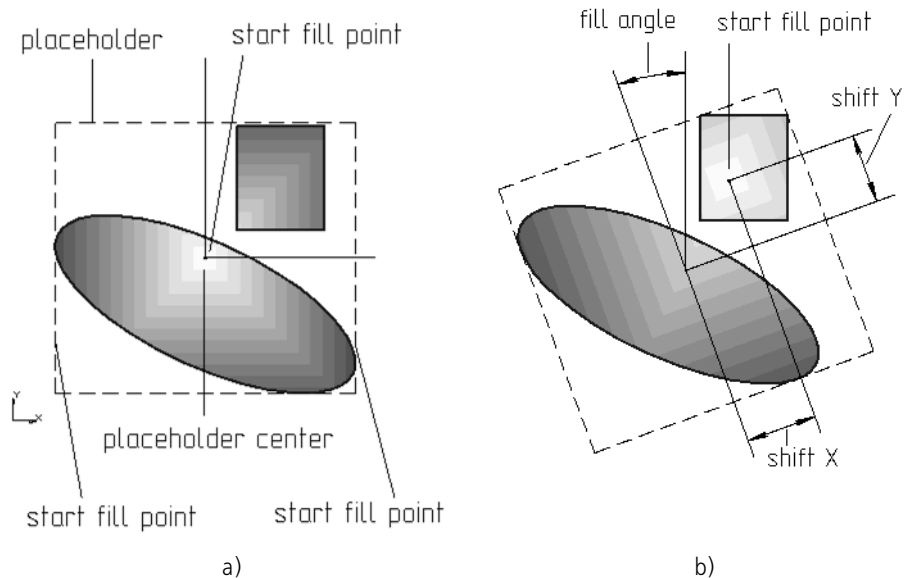

Fig. 3.2.87. Fill parameters when drawing:
 a) in the absence of shift or angle, b) after specifying shift and angle

The **start point** of a fill is a point where you specify the start color. By default, the start point is at the center of the dimensional rectangle.

The **start fill line** is a line passing through the start point. Color graduation for certain fill types begins from the start line or ray.

The **end line** of the fill is an end line or ray in which the end color is set.

The Table 3.2.8 describes gradient fill types. Examples with step-by-step color variation, zero shift of the start point and zero fill angle are provided for illustrative purposes.

Tab. 3.2.8. Description of gradient fill types

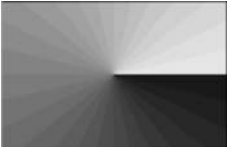

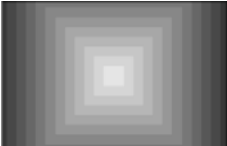

Sample fill
 (with step-by-step
 color variation)

Fill type description

Linear— color changes from the start line to the end line. The start and end lines are on parallel sides of the dimensional rectangle. Linear fill has not start point.

Tab. 3.2.8. Description of gradient fill types

Sample fill (with step-by-step color variation)	Fill type description
	Cylindrical — color changes from the start line to end lines. The end lines are sides of the dimensional rectangle parallel to the start line.
	For angular and conical fills, the start and end lines are rays drawn from the start point. Angular — color changes from the start ray to the end ray in a circular direction. The distance between the start ray and the end ray is 360 degrees.
	Conical — color changes from the start ray to the end ray in a circular direction. The distance between the start ray and the end ray is 180 degrees.
	Radial — color changes in a radial direction from the start point to a most distant point on the side of the dimensional rectangle.
	Square — color changes in directions perpendicular to the sides of the dimensional rectangle. The start color is in the start point, the end color is on the most distant side of the dimensional rectangle.

Fill angle determines the angle of fill rotation relative to the start point inside the fill area. When you change the fill angle, the dimensional rectangle will also rotate by the specified angle. For linear fill, the angle determines the change in the direction of color variation.

The position of the start point of the fill can be changed by the length of the **shift** relative to the center of the dimensional rectangle. If there is no shift, the start point is at the center of the dimensional rectangle.

If necessary, you can increase the **transparency** of each fill color. 100% transparency means that the object is invisible. By default, the values of “Transparency” (“Start Transparency”, “End Transparency”) are 0%, meaning that fills are created non-transparent.

Several intermediate colors and transparency levels may be additionally defined in the fill.

3.2.13.3.2. Creating a Fill

To fill one or several areas, click **Fill**.

Specify fill borders and parameters.

To copy the parameters of a fill previously created in a document, click the **Copy Properties** button on the Special Control panel.

The cursor will change in appearance.

Move the cursor to the contour limiting the fill whose parameters you want to copy. Once the face is highlighted, press the left mouse button. To move the parameters, specify the fill area. The fill with copied parameters will appear in the selected area. If necessary the text can be edited.

One or several filled areas will appear on the screen, letting you control how you specify fill areas and parameters.

When all the required areas are hatched, click the **Create Object** button. The fill will be fixed in the document, and the system will wait for you to specify the border for the next fill.

3.2.13.3.3. Fill Parameters

Fill parameters can be configured using control elements on the **Fill** tab of the Property bar.

The set of control elements depend on the fill type selected in the **Type** group.

They are represented in Table 3.2.9.

Tab. 3.2.9. Fill control elements

Element	Description
Type	List of fill types. To change the current fill type, open the list and select the required type.
If you select the monochromatic fill type, the following control elements are available.	
Color	The list lets you select the fill color. Clicking the Another Color item displays the advanced dialog of the color selection.
Transparency	Control element that lets you set transparency* of the selected color. <ul style="list-style-type: none"> ▼ If Zero-level Transparency% 0% is set, the fill is completely non-transparent. To increase transparency, move the slider to the right. ▼ The slider in the rightmost position sets Transparency to 100%. The fill will be completely transparent.
If you select other fill types in the Type list (gradient: linear , cylindrical , etc.), the following control elements are available.	
Color 1	The lists that enable the selection of the start and end colors of the fill.
Color 2	Clicking the Another Color item displays the advanced dialog of the color selection.

Tab. 3.2.9. Fill control elements

Element	Description
Angle	<p>Control element that lets you specify the fill rotation angle relative to the start point inside the area.</p> <p>Enter a value or select one from the list of previously entered values and frequently used angles.</p> <p>This field is not available for the radial fill.</p>
X-axis Offset Y-axis Offset	<p>The fields for entering or presetting the relative shift of the fill start point from the center to the sides of the dimensional rectangle with a counter. Values can vary between -100 and 100%.</p> <ul style="list-style-type: none"> ▼ If the value is set to 0%, there is no shift — the fill start point coincides with the center of the dimensional rectangle. ▼ The value of 100% for Shift X or Shift Y means that the fill start point is on the side (contour) of the dimensional rectangle. <p>When you move a point with the mouse or rotate the fill, the shift value is calculated and entered into these fields.</p> <p>For cylindrical fill, the Shift field is available for entering the shift value of the start point in the direction toward the start or end line of the fill. These fields are not available for the linear fill.</p>
Transparency	<p>The control elements which are used to specify the transparency* of the selected Color 1 and Color 2.</p> <ul style="list-style-type: none"> ▼ If you set Start Transparency (End Transparency) to 0%, the fill specified in fields Color 1 (Color 2) is completely non-transparent. To increase the transparency of a specific fill color, move the relevant slide to the right. ▼ The slider in the rightmost position sets Start transparency (End transparency) to 100%. The fill will be completely transparent.
 Advanced	<p>When pressing the key, the advanced fill control dialog will be displayed. The dialog defines intermediate colors and transparency levels as well as their location in the fill (See Section 3.2.13.3.4).</p>
Color Gradients	<p>The group of switches enabling the selection of a method of the fill color changing from Color 1 to Color 2.</p> <ul style="list-style-type: none"> ▼ If the switch Smooth Color Gradient is active, the color gradient will be smooth. ▼ If the switch Specified Number of Steps is active, the color gradient will match a specified number of steps. The field for entering or specifying the number of steps with a counter becomes active, from 1 to 255.
	
	

* Some printers do not support printing of transparent fills. In these cases when customizing printing it is recommended to enable an alternative way of printing (see Sections 8.1.2.2 on p. 1634 and 8.2.5.2 on p. 1652).

3.2.13.3.4. Additional color gradients and transparency levels of a fill

When building or editing gradient fill you may create **additional** intermediate colors and/or change transparency level of some of its area (See Fig.3.2.88).

For this, press **Advanced** button on the Properties button and call the context menu command with the same name.

Fig. 3.2.88. Radial fill before and after the adding several colors and levels of transparency

The dialog of advanced fill control will be displayed (See Fig.3.2.89).

In the dialog window there is a rectangle sample with the color gradient defined on the Properties toolbar from **Color 1** to **Color 2** and transparency levels — **Start** and **End**. If non-zero transparency was defined on the Properties toolbar, in the upper half of the rectangle black-and-white cells will be displayed the brightness of which will help assess the transparency level.

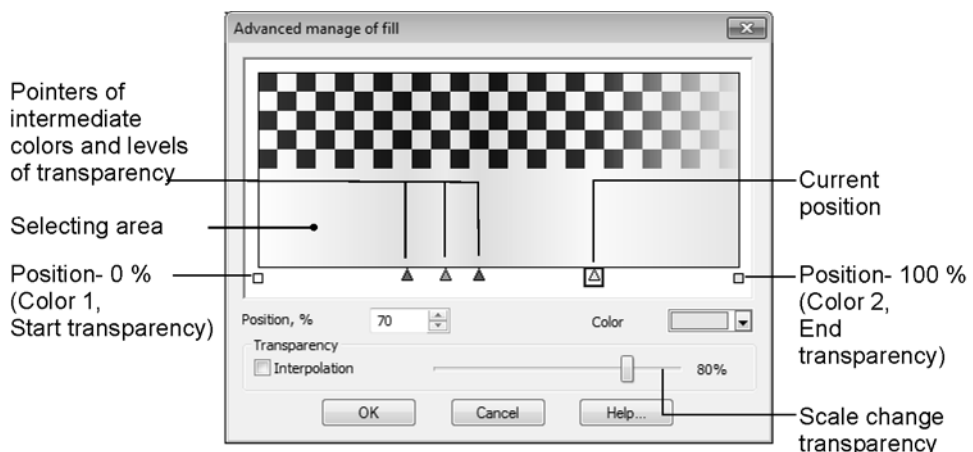

Fig. 3.2.89. Advanced fill control dialog

To define additional colors and/or transparency levels, do the following.

1. Create a new position. In this dialog window double click on the location of a new color or transparency level between **Color1** and **Color2**. In the bottom of the window a triangle-type item pointer will appear.

You can create several positions.

The current position pointer will be displayed in the frame (See Fig. 3.2.89). Change the current position with the mouse click on the required pointed or using the key combinations `<Ctrl> + <▶>`, `<Ctrl> + <◀>`.

2. Move the pointer to the required position with the mouse or keys `<▶>`, `<◀>` or by the input or counter adjustment of the integer from 1 to 99 in the **Position** field. When moving with the mouse the cursor will switch to two-sided arrow.

In the **Position** field a value in percentage will be displayed showing the current position location relative to the original fill point. Initial color corresponds to position 0, end fill color corresponds to 100% .

The **Position** field is available if the pointer of additional position is the current one.

3. Define the color in the current position in the color selection dialog clicking twice the position pointer or using the **Color** control. By default the color in the created position is an intermediate one between the colors in the nearest positions.

▼ To create an area in the fill with the constant color, move the position pointer with the mouse to the required distance with the `<Ctrl>` key pressed.

▼ To remove the intermediate color, “drag” this pointer with the mouse outside the window. After the cursor changes color, release the pointer. You can also delete the intermediate color pressing the `<Delete>` key after the relevant position has been accepted as the current one.

If you need to enter additional colors without changing the transparency, the **Interpolation** option of the **Transparency** group must be enabled.

4. Define additional transparency levels in the fill. To do this, make the pointer the current one at the border of the area where transparency will change.

The **Interpolation** option in the **Transparency** group controls transparency presets, and the scale with the slider is used — to define and display transparency level in the current position. The transparency value is shown in percentage to the right from the scale.

▼ By default the **Interpolation** option is enabled. This means that the transparency in the created position is a value interpolated between the transparency values of the neighboring positions, for example, the start and the end one.

It is impossible to randomly change the transparency in the current position— changing scale is inaccessible.

▼ If the **Interpolation** option is disabled, the transparency changing scale will become accessible. To define a new value, move the slider to the required position with the mouse or keys `<▶>` and `<◀>`.

If the transparency value is equal to 0%, the fill in this position is considered to be fully non-transparent, if it is 100%— it is fully transparent. The color in this case fully corresponds to the color displayed in the **Color** control field.

To cancel the additional transparency level without the position deletion, make the position as the current one and enable the Interpolation option.

After defining intermediate colors and transparency levels press **OK**.

The start and the end color, as well as the start and the end transparency of the fill may be changed making positions 0% and 100% the current ones. After the changes has been effected, the values will automatically be displayed on the Properties toolbar.

3.2.13.3.5. Editing the Fill

Fill handles are the start point and fill contour handles.

Bear in mind the following when editing the fill.

- ▼ In the mode of editing handles for all fill types, except monochromatic and linear fill, you can change the position of the start point.
- ▼ To prevent the fill color from changing when highlighted, enable the option **Always Show Fill in Specified Color** in the dialog that appears after you click **Service— Options— System— Graphic Editor— Edit**. In this case, only the fill contour will be highlighted when you select it.

3.2.14. Complex Objects

In KOMPAS-3D, complex geometric objects include:

- ▼ offset curves,
- ▼ contours.

A common property of these objects is the fact that they are selected and edited in their entirety. You can work with individual objects making up such a complex feature only after exploding it. To explode an object, click **Edit — Explode**.

3.2.14.1. Contour

To create a contour consisting of parts of intersecting geometric objects, click **Create Contour**.

Further steps are identical to those described in Section 3.2.13.1.2 on p. 957.

The control of the source objects is described in Section 3.4.2.1.1 on p. 1121.

Fig. 3.2.90. Sample of contour created through tracing by arrow

3.2.14.2. Equidistant Line

To draw an equidistant line of any geometric object, click **Equidistant Line**.

Specify the object whose equidistant line you want to create. The equidistant line ghost will be displayed.

Configure the equidistant line settings (see Section 3.2.14.2.1). All changes you make are reflected in the ghost.

Once you complete settings, click the **Create Object button**. The equidistant line will be fixed in the document, and the system will wait to specify the border for the next equidistant line.

3.2.14.2.1. Equidistant Line Parameters

Equidistant line parameters are configured using items on the **Equidistant Line** tab of the Property bar. They are represented in Table 3.2.10.

Tab. 3.2.10. Equidistant line control elements

Element	Description
Radius 1	Distance from the object to the equidistant line on the left.
Radius 2	Distance from the object to the equidistant line on the right.
Corner Passing	
	Method of passing corners with cut (Fig.3.2.91, a).
	Method of passing corners via fillet (Fig.3.2.91, b).
Type	
	Creating an equidistant line on the left of the object.
	Creating an equidistant line on the right of the object.

Tab. 3.2.10. Equidistant line control elements

Element	Description
	Building an equidistant line on two sides of an object (Fig.3.2.92, b).
Mode	
	Remove degenerated portions of an equidistant line (Fig.3.2.93, a).
	Retain degenerated portions of an equidistant line (Fig.3.2.93, b).
	If the Retain Degenerated Portions switch is active, the corners are passed only with cut. The group of switches Corner Passing is unavailable.

a)

b)

Fig. 3.2.91. Corner passing: a) with cut, b) via fillet

a)

b)

Fig. 3.2.92. Equidistant line: a) on one side of the object, b) on both sides

Fig. 3.2.93. Equidistant line: a) without degenerated portions, b) with degenerated portions

3.2.14.3. Equidistant Line by Arrow

To draw an equidistant line of a contour formed through tracing by arrow, click **Equidistant Line by Arrow**.

The steps for forming a contour through tracing by arrow are described in Section 3.2.13.1.2 on p. 957.

The parameters of an equidistant line by arrow are the same as in the case of an equidistant line of an object (see Section 3.2.14.2.1 on p. 968).

3.2.15. Chamfers and Fillets

By default, an arbitrary chamfer and fillet are created using the line style of the first of the two objects. A chamfer or fillet on object corners have the same style as the object.

3.2.15.1. Chamfer

To draw a line connecting two intersecting curves, click **Chamfer**.

By using group of switches **Type** on the Property bar, specify the chamfer construction method: by two sides or by a side and angle.

Enter chamfer parameters in the fields on the Property bar.

Select the first and the second object, between which you need to draw a chamfer.

Fig. 3.2.94. Creating a chamfer: a) original image, b) result of the command

3.2.15.1.1. Controlling the Object Trimming

There are two methods of creating a chamfer/fillet:

- ▼ with object trimming,
- ▼ without object trimming.

When using the first method, the pieces of the first/second object remaining after creating a chamfer/fillet, are automatically deleted; when using the second method, they remain.

You can choose the method for creating a chamber for both its elements individually. To do this, in the groups **Element1** and **Element2** on the Property bar, activate the switch **Trim Element** or **Do Not Trim Element**. By default, both of them has the **Trim Object** switch active.

Fig. 3.2.95. Creating a Chamfer/Fillet: a) with element trimming, b) without element trimming

3.2.15.1.2. Creation of the Intersection Notation of Truncated Objects

An intersection notation can be created on trimmed objects. It means that when creating a chamfer/fillet, objects will be extended by thin lines to their intersection point. An intersection notation can be also constructed separately by using the **Intersection Notation** command, see Section 3.3.12.19 on p. 1065.

In order to enable or disable creation of the intersection when creating a chamfer/fillet, enable the required switch in the **Intersection Notation** on the Property bar.

Fig. 3.2.96. Creating a Chamfer/Fillet: a) if the intersection creation is enabled, b) if disabled

The intersection will be created, if the chamfer/fillet is created with trimming of one of the specified objects (see Section 3.2.15.1.1 on p. 971).

Default parameters values defined in the **Intersection Notation** section of the settings dialog are used for constructing (see Section 9.2.6.12 on p. 1785).

By default the created cosmetic intersection is in no way connected to the objects, specified during the course of the command, and can be edited separately.

3.2.15.2. Chamfer on Object Corners

To create chamfers on corners of the following object types: a contour, polyline or polygon, click **Chamfer on Object Corners**.

By using group of switches **Type** on the Property bar, specify the chamfer construction method: by two sides or by side and angle.

Enter chamfer parameters in the fields on the Property bar.

Select a corner of a contour, a polygon or a polyline to create a chamfer. The first object used in building a chamber will be the segment closest to the specified point.

By default, a chamfer is built only on the specified corner of the contour. In this case, the **At Selected Corner** switch is active in the **Mode** group on the Property bar. In order to create chamfers with specified parameters simultaneously at all corners of a selected contour, activate the switch **At All Contour Corners**.

activate the switch **At All Contour Corners**.

Fig. 3.2.97. Building chamfers on all corners of a rectangle

3.2.15.3. Fillet

To draw a fillet by circle arc between two intersecting objects, click **Fillet**.

Enter the fillet radius in the respective field on the Property bar.

Select to objects between which you need to construct a fillet.

Fig. 3.2.98. Building a fillet: a) initial image, b) result of building a fillet

3.2.15.4. Fillet Object Corners

To create a fillet by circular arcs on the corners of the following type of objects: a contour, polyline or polygon, click **Fillet Object Corners**.

Enter the fillet radius in the respective field on the Property bar.

Select a corner of a contour, a polygon or a polyline to create a chamfer.

By default, only the specified contour corner will be rounded. In this case, the **At Selected Corner** switch is active in the **Mode** group on the Property bar. For fillets with specified parameters to be created simultaneously at all corners of a selected contour, activate the switch

At All Contour Corners.

Fig. 3.2.99. Creating fillets on all vertices of a polygon

3.3. Dimensions and designations

3.3.1. General Dimension Handling Techniques

KOMPAS-3D allows creation of any of the standard dimension variants in a graphic document. It is possible to indicate several types of linear, angle, radial, diameter dimensions, as well as height and arc dimensions. Also, a special method of dimensioning is available, in which the system indicates dimensions automatically.

The dimensioning commands are grouped in the menu **Tools – Dimensions**, and the command calling buttons are located on the **Dimensions** bar (Fig. 3.3.1).

Fig. 3.3.1. **Dimensions** bar

The general sequence of steps while dimensioning is:

1. Calling of the command for a specific type of dimension or the automatic dimensioning command.
2. Specifying the object(s) to dimension.
3. Setting up the dimension line view using the Settings bar tabs (see Sections 3.3.1.1 and 3.3.1.2).
4. Editing (if needed) the dimension text (see Section 3.3.1.3) and specifying its position.

3.3.1.1. Property Settings

Fig. 3.3.2. Usage of the **Dimension** tab of the Property bar while specifying a linear dimension

The dimension control widgets located on the **Dimension** tab are presented in Table 3.3.1.

Tab. 3.3.1. Control elements on the **Dimension** tab

Element	Description
p1, p2, p3, p4	Handle coordinate fields. In Fig.3.3.12 on p. 991, four points are shown that define the posing of a linear dimension on a leader shelf. If manual text positioning is selected (see Table 3.3.3 on p. 977), the field p3 specifies also the location of the dimension text; if on-shelf location is selected, the field specifies the leader's start point. The p4 field is available in case one of the on-shelf location variants is selected (see Ibid.).

Tab. 3.3.1. Control elements on the **Dimension** tab

Element	Description
Type	The element specifying dimension line directions. Depending on the type of the dimension created, this element can have different appearance and contents (see Table 3.3.2).
Text	The field containing the dimension text. To edit the default text or input a new text, click in the field. Detailed information about dimension texts is presented in Section 3.3.1.3 on p. 979. Direct symbol input into the Text field is impossible.

Tab. 3.3.2. The **Type** element

Dimension Type	Contents of the Type Element
	Linear Dimension Horizontal
	
	
	Arc dimension Parallel Extension Lines
	Extension Lines from Center
	Level Dimension Front View or Cut
	Top View with Leader
	Top View Immediately in Drawing
	Diameter Dimension Full extension line
	
	Radial Dimension Radial Dimension Not from Circle Centerpoint

Tab. 3.3.2. The **Type** element

Dimension Type	Contents of the Type Element
	Radial Dimension from Circle Centerpoint
	Angular Dimension Minimum (acute) angle
	Maximum (obtuse) angle
	Greater than 180°

* Only for a simple linear dimension.

3.3.1.2. Options Settings

Fig. 3.3.3. The **Options** tab on the Property bar while specifying a linear dimension.

The dimension control elements on the **Options** tab are presented in Table 3.3.3.

Tab. 3.3.3. Control elements on the **Options** tab

Element	Description
	Extension line The radio button specifying the extension line visibility. Only for dimensions with extension lines. For radial dimensions and a linear dimension with a broken line, there is only one switch in the Parameters tab. For any other linear dimensions and for diameter dimension there are two such switches.
	Arrow The list serves to select the type of the dimension arrow. The list of arrows available for selection as well as the order of arrows in the list is defined by the setting of the arrows filter made for the current document (see Section 9.2.6.10.5 on p. 1774).

Tab. 3.3.3. Control elements on the **Options** tab

Element	Description
Text Location	This list serves to specify the desired way of positioning the dimension text: Auto , Manual , On Leader shelf Left , On Leader shelf Right , On Leader shelf Top , On Leader shelf Bottom . For any dimensions, except a linear with a common dimension line, angular with a common dimension line and height dimensions. For details on dimension text location control see Section 3.3.1.5 on p. 987.
Text Location	This list serves to select the choice of positioning a dimension text relative to the dimension line: Parallel, above line , Parallel, in the line break , Horizontally, in the line break . For any dimensions, except a linear with a common dimension line.
Placing arrows	The group of radio buttons for selection of arrow location variants relative to the dimension extension lines. <ul style="list-style-type: none"> ▼ If you need to have the arrows placed inside the range between the extension lines, activate the Inside switch. ▼ If you need to have the arrows placed outside the range between the extension lines, activate the Outside switch. ▼ If you would like the system pick the arrows placement option automatically, then activate the Auto switch.
Branchings	The group of radio button that allow to select the method to create branches: From Shelf Start , From Shelf End . Only for a simple radial dimension. The switches are available if one of the types of arrangement of dimension text on leader shelf has been selected from the Text Location list.
Gap/Length	The group of elements allows creation of dimension lines with gaps or fixed-length (see Section 3.3.1.8 on p. 989). For linear (except dimension with broken line), diameter and radial dimensions. Elements are available when extension lines display is enabled.

Tab. 3.3.3. Control elements on the **Options** tab

Element	Description
Leader Parameters	The group of fields serves to define a leader line parameters. For any dimensions, except a linear with a common dimension line. Creating a dimension with a text placed on a leader shelf, the length of the leader is displayed in the Length field, and the Angle field represents the slope angle between the leader and the main axis. You can input these values from the keyboard if the automatic object creation option is disabled (see Section 1.4.2.10 on p. 93) and only when the leader has been created (the shelf start point has been specified), editing of the created leader is actually performed in these fields.
Bend angle	The field for entering a number of dimension line bend angle. Only for a bent radial dimension.
Pointer from Text to Arc	The option to manage the drawing of the pointer from a dimension text to a measured arc. For arc dimensions only.
By default	If the option is enabled, all current settings on the Options tab will be used to create all the following dimensions of the given type until the end of the session. If the option is disabled, then the setting affects only the current dimension (the one being created).

3.3.1.3. Dimension Text input

Character input into a dimension text is performed in a special dialog (Fig. 3.3.4) called by clicking in the field **Text** on the **Dimension** tab.

The control elements of this dialog are represented in Table 3.3.4.

Inputting and editing a dimension text, you have to pay attention to the following:

- ▼ If the value range limits are included in the dimension text, and the class of accuracy is not, then the nominal value will not be shown in the dimension text.
- ▼ If the dimension value range limits display is enabled, but the class of accuracy is not defined, then changes in the dimension geometry (for example, when rebuilding an associative dimension) do not cause recalculation of the value range limits.

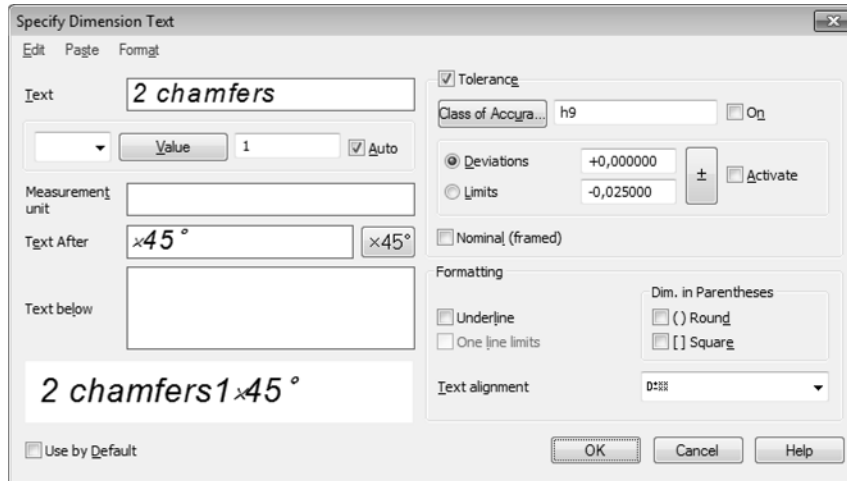

Fig. 3.3.4. Linear dimension text Input dialog

Tab. 3.3.4. Dimension text input dialog

Element	Description
